PROVINCE DEVELOPS ANIMAL HUSBANDRY--The number of draft cattle on hand in 1981 was 6.1 million head and was 18.4 percent more than in 1978. The number of draft cattle on hand by the end of June this year was 6.295 million heads and was 11.5 percent more than in the corresponding period of last year. The province now has some 50,000 specialized and key households in livestock production. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 16 Aug 82]

BRIEFS

GRAIN, OIL PROCUREMENT--By the end of July, Hubei Province had procured 2.47 billion jin of summer grain and stored it in granaries, overfulfilling its procurement quota by 37 percent. The province procured some 340 million jin more than in 1979, a year of a big bumper harvest. By the end of July, the province had stored 4.348 million dan of rapeseeds, overfulfilling its procurement quota by 90 percent. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 5 Aug 82]

BRIEFS

SPECIALIZED HOUSEHOLDS--Since the implementation of the production responsibility system, rural areas in Changde, Yiyang, Yueyang, Hengyang, Lingling and Chenzhou Prefectures have some 311,000 specialized households and key households. These specialized households and key households have made good use of the local natural resources to promote planting, animal husbandry and processing industry. They work very hard to bring their strong points into full play and have become rich. If the average output value of a standard agricultural worker is more than 800 yuan, the average output value of specialized households is as much as 1,500 to 3,000 yuan. A woman peasant in Taoyuan County who is specialized in breeding rabbits is able to get an output value of 4,000 yuan a year. Eighteen specialized households and key households in Huarong County were able to earn 10,000 yuan last year. [Changsha Hunan Provincial Service in Mandarin 1100 GMT 9 Aug 82]

EARLY RICE HARVEST--Hunan Province reaped a good early rice harvest this year despite serious natural disasters. According to statistics, the total output of early rice was 19.96 billion jin, 307 million jin more than last year and an increase of 1.61 percent. This is the highest record of the province. Nine out of the 16 prefectures and municipalities have increased output, of which, Yiyang Prefecture has increased its output by 123 million jin, an increase of 5.29 percent. Sixty-six out of the province's 101 counties have increased output. Of which, 14 have increased it by more than 100 percent. Although the seeded area of early rice was reduced, the per unit area yield has increased by 18 jin overlast year. The province has been able to reap a bumper early rice harvest since the agricultural production responsibility system has been further stabilized and perfected and the peasants' enthusiasm has been promoted. By the end of March, 99.4 percent of the province's production teams had established the production responsibility system. Furthermore, scientific agricultural measures have been implemented, and the weather is favorable for crops. [Changsha Hunan Provincial Service in Mandarin 1100 GMT 9 Aug 82]

EARLY RICE--Changsha, 10 Aug (XINHUA)--Hunan Province has harvested 9.98 million tons of early rice this year, 153,500 tons more than last year, provincial authorities announced today. Total and per unit outputs of early rice this year are all-time highs, authorities said. Hunan Province is a major early rice producer of China's. The crop accounts for 40 percent of the province's annual output of grain. [Text] [Beijing XINHUA in English 1524 GMT 10 Aug 82]

JIANGSU FLOODED FARMLAND QUICKLY DRAINED

OW071353 Beijing XINHUA in English 1201 GMT 7 Aug 82

[Text] Nanjing, 7 Aug (XINHUA)--Most of the 660,000 hectares of low-lying farmland swamped by rainstorms in Jiangsu Province in July were drained in one or two days, according to the provincial government.

Between 9 and 24 July, rain hit 68 of the 75 counties and cities in Jiangsu Province. Precipitation exceeded 100 millimeters. In some places, the rainfall topped 300 millimeters.

Most of the local rivers rose above the warning mark.

No river dike was breached along the hundreds of kilometers protected.

The first and second communist party secretaries and the acting governor gave guidance in the battle. People's Liberation Army units helped the people guard the dikes and drain the fields.

Two million horsepower of pumps were used for drainage.

When the rising water level of the Chuhe River menaced the Beijing-Shanghai Railway, over 10,000 cadres and peasants stood guard on the river dikes. Safe operation of the railway was ensured.

A good wheat harvest was reaped by the province this summer and the people are now working for another good harvest this autumn.

BRIEFS

IMPOVERISHED PRODUCTION TEAMS--Under the support of the Yingkou County CPC Committee, a number of impoverished production teams in the mountainous areas of this county have improved their backward situation. By the end of 1981, production teams with an average per capita income of only 50 yuan decreased from 386 in 1978 to 52, about 2.5 percent of the total number of production teams in the county. In 1980, the Yingkou County CPC Committee organized 21 committees, offices and bureaus to help 101 production teams in five communes develop breeding and planting undertakings, thus succeeding in bringing prosperity to the backward mountain areas. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 3 Aug 82]

WHEAT OUTPUT--Faku County, Liaoning Province, has reaped a bumper wheat harvest this year. According to statistics, the county's total output reached over 15 million jins, a 2.76 million jin increase over the 1981 figure and topping previous peaks. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 14 Aug 82]

LIAONING **INSECT PESTS--Our reporters have learned from the provincial farm crops insect pests forecast station that since early August the snout moth's larva pest is spreading throughout most of Liaoning Province. This serious plague will hit Jianchang County in Chaoyang Prefecture; Heishan, Xingcheng and Suizhong Counties in Jinzhou Municipality. The plague is expected to expand into a number of areas. Localities in the province should vigilantly conduct examinations and prevention work in a timely manner. [Text] [SK090958 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT** 8 Aug 82]

BRIEFS

WHEAT OUTPUT--In spite of the drought this year, Jirem League, Nei Monggol Autonomous Region, has reaped a bumper wheat harvest. The output of its 250,000 mu wheat crop is expected to reach the peak scored in 1981. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 16 Aug 82]

IH JU LEAGUE AFFORESTATION--Ih Ju League, Nei Monggol Autonomous Region, has mobilized the masses to plant trees during the rainy season. As of mid-August, the league forested 1.12 million mu and rushed to plant 386,000 mu of fine-quality forage grass. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 17 Aug 82]

REGIONAL FORESTRY--According to statistics compiled by the Nei Monggol Autonomous Regional Forestry Department, the region planted 5.45 million mu of trees in spring and rainy seasons [this] year, a 980,000 mu increase over the 1978 figure. In addition, the people throughout the region obligatorily planted 31 million trees and 164,000 mu of forests. From 1979 to 1981 the region planted 14.75 million mu of trees and scored a 10 percent increase each year. Rural people in the region planted 270 million trees and scored a 38 percent increase each year. [SK170947 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 16 Aug 82]

LIVESTOCK PRODUCTION--While people throughout the country are jubilant over the imminent convocation of the 12th party congress, good news is reported from the livestock production front in Nei Monggol. According to statistics made available by the Regional Statistical Bureau, by the end of June the region had 47.2 million head of livestock, an increase of 1.52 million head over the corresponding 1981 figure. This figure was higher than the previous record in 1980 by 650,000 head. The total number of cattle, horses, camels, sheep and goats stood at 42.4 million, topping the previous record in 1965 by 420,000. Some 26.6 million head of the livestock, 56.4 percent of the total, are owned by the peasants. [SK141052 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 13 Aug 82]

SUGAR OUTPUT--Since the third plenary session of the 11th CPC Central Committee, Nei Monggol Autonomous Region has made marked progress in sugar refinement. According to statistics, the region has turned out 279,000 tons of white sugar over the past 3 years, from which the region has accumulated about 40 million yuan of funds for the state. In addition, the region increased its beet planted acreage from 790,000 mu in 1978 to 980,000 mu in 1981 and its beet output from 380,000 tons in 1978 to 780,000 tons in 1981. The region has planted 1.01 million mu of sugar beets this year. Its beet output is expected to be over 1 million tons. [SK210558 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 20 Aug 82]

GUIDELINES GIVEN FOR BUILDING SUBURBAN FARMS TO SUPPLY YINCHUAN

Yinchuan NINGXIA RIBAO in Chinese 27 Jun 82 p 2

[Article by Autonomous Region CCP Committee Investigation Unit: "Build Suburban Yinchuan Into a Non-Staple Food Production Base With All Possible Speed--a Survey of Development of Economic Diversification in Suburban Yinchuan"]

[Text] (1)

As a result of the liberalization or rural economic policies, increases in purchase prices paid for farm products, establishment of agricultural production responsibility systems, and readjustment of the internal structure of agriculture in the wake of the Third Plenary Session of the 11th Party Central Committee, simultaneously with continued increases in food production in suburban Yinchuan, definite development has also occurred in forestry, animal husbandry, sideline occupations, fisheries, processing industries, and such economically diversified industries.

In 1981 suburban Yinchuan passed the 100 million jin mark in food production for the first time, to set an all-time high. Despite severe freeze damage done to vegetable production, it fulfilled 79 percent of plansales to the state. Despite reductions in the area sown to oil-bearing crops, increases in yields per unit of area brought an increase over the previous year in total output. Tremendous increases took place in both the area planted to sugarbeets and sugarbeet output, total output increasing by 38 percent over 1980. In 1981 both afforestation and growing of seedlings overfulfilled plan. At the end of the year, large livestock animals in inventory numbered 17,663, a 4.3 percent increase over the previous year. The number of live hogs in inventory decreased by 3.4 percent over the previous year; however, the number of fattened hogs removed from inventory increased by 4.9 percent over the same period during the previous year. Chicken raising and marten raising also saw definite development. During the last 3 years, Yinchuan suburban commune member household sideline occupations have developed fairly rapidly. Throughout the suburbs, a group of specialized households and key households for the raising of livestock and poultry already exist. A representative sampling shows that last year commune member household sideline occupation earnings accounted for a general 20 to 40 percent of gross earnings. At Luhua Fourth Brigade in Luhua Commune, commune member household sideline occupation earnings amounted to more than 70,000 yuan, an average of somewhat more than 1,300 yuan per household or somewhat more than 270 yuan per person and about 60 percent of commune member household gross earnings. Accompanying development of production has been an increase in output of agricultural sideline products. Purchases of agricultural sideline products in suburban Yinchuan substantially fulfilled state plan. Last year, except for purchases of vegetables and fresh eggs, which were less than the previous year, purchases of all other goods increased. Sales of live hogs for the year as a whole totaled 6,384 head, each head averaging an undressed weight of 204 jin, which was the highest undressed weight for fattened hogs sold in the irrigation district. Sheep and goat assigned procurement quotas were fulfilled with 2.693 head for an 18 percent overfulfillment of plan. Seven thousand tons of sugarbeets were sold to the state, making it the only county (or district) in the irrigation district to overfulfill sugarbeet sales quotas.

Though growth has occurred in suburban Yinchuan's economic diversification, speed of growth has not been rapid; kinds of diversification have not been numerous; and development has been also unbalanced from one commune and brigade to another. A trend toward decline still exists in the production of some items. The most prominent problem is 3 consecutive years of decline in production of vegetables. Vegetable sales to the state during 1978 were 103,450,000 jin. In 1979 it was 94.63 million jin; in 1980, 75.48 million jin; and last year only 71.02 million jin, making it impossible to find a solution to the problem of vegetables for the people in the municipality during the slack season in vegetable production. Numbers of hogs, sheep and goats, and chickens raised declined too. At the end of last year, sheep and goats in inventory numbered 56,339, a 1.37 percent decline from the previous year. In 1979 the number of ducks raised increased to somewhat more than 70,000, but declined last year to somewhat more than 10,000. The fish raising area is small and yields low. Last year only 4,500 jin of fish were produced. The foundation for agricultural sideline product processing is frail. Only a small number of communes and brigades in the close-in suburbs operate processing plants for non-staple foods and livestock feeds. Output value from commune and brigade enterprises last year fell by 22.7 percent from 1980. As a result of agricultural sideline products provided the city by state purchases, last year pork sales to the state averaged 13.1 jin per capita; mutton or goat meat sales averaged 0.54 jin per capita, and fresh eggs averaged 1 jin per capita. Quantities of pork, mutton or goat meat, and fresh eggs sold the state by the suburbs as a whole amounted to 14 percent, 6.3 percent, and 6.7 percent respectively of sales by the city as a whole. Supplies of beef, poultry, and aquatic products for state-owned enterprises in the city were virtually entirely dependent on transportation from elsewhere.

(2)

In view of the foregoing, does suburban Yinchuan have the conditions required for the building of non-staple food production bases? The answer is yes. Yinchuan's suburbs have an area of somewhat more than 554,000 mu including almost 210,000 mu of cultivated land, about 100,000 mu that can be cleared for farming, more than 28,000 mu of lakes, more than 34.000 mu of river flats, and more than 50,000 mu of alkaline flats. Following institution of production responsibility systems, about one-third of the workforce is surplus. In the far-out suburbs there are large tracts of land suitable for development of grain and sugarbeet production, the forestry industry, fisheries, and the raising of cattle and sheep. In the close-in suburbs, people are numerous and transportation is convenient, and the city's excrement and residue from its processing industries, and such by-products, may be used for the development of vegetable growing, livestock and poultry raising industries, and processing industries. A very great potential exists for development of economic diversification.

First of all, as far as the farming industry is concerned, sufficient vegetables should be grown to satisfy the needs of the city. Yinchuan's suburbs lie close to the city. It has a plentiful supply of fertilizer and climatic conditions are relatively good, making them suitable for the growing of vegetables. Figured on the basis of the farming area for the suburbs as a whole, between 1976 and 1981, the suburbs provided the state commodity vegetables at an average rate of somewhat more than 6,500 jin per mu. Conditions are particularly favorable for the growing of Chinese cabbage, with yields of more than 10,000 jin per mu being produced between mid-July and the end of October, maximum yields reaching somewhat more than 25,000 jin per mu. Prospects are also very good for the production of vegetables in plastic enclosures during the winter and spring seasons. This plus the learning of advanced vegetable growing techniques and how to store vegetables well during the winter could mean a change in Yinchuan's vegetable shortage during the slack season in production.

Yinchuan's suburbs lie fairly close to sugar refineries, making it easy to get technical guidance and sell sugarcane. There is a lot of land in the far-out suburbs, so development of sugarbeets also offers great advantages. Last year Luhua Fourth Brigade in Luhua Commune grew 300 mu of sugarbeets, most of them intercropped, each household averaging 5.5 mu, producing more than 12,500 jin of sugarbeets for average per capita earnings of more than 100 yuan. Some brigades used scientific intercropping methods, making full use of cultivated land to develop sugarbeet production. The building of a forestry industry has far-reaching significance for the beautification of the city and the suburban environment, for regulating the climate, and for improving the ecological balance. It is also a very important way in which to generate and amass wealth. Lojiazhuang Brigade in Yinxin Commune is a close-in suburban vegetable growing brigade with many people relative to the amount of land. Beginning in 1977, it carried out a vigorous program to plant trees by both the collective and individuals at the same time. Today the brigade has more than 278,000 trees, or 105 trees per capita. Were Yinchuan's suburbs to plant trees and create forests year by year in all the wasteland river flats, ditches and ravines suitable for afforestation, they would play a major role in the promotion of agriculture, animal husbandry and the development of economic diversification. Both conditions and markets exist for melons and fruits, and the growing of grapes and other fruits by commune members' families holds particularly good prospects. It would be a good way both to satisfy the needs of the city and to increase commune member earnings. During the past 2 years, Honghua and Yinxin communes have developed fairly rapidly. If the cultivated area were appropriately enlarged and farming techniques improved, great increases could be made in the quantities of melons and fruits provided the city.

Secondly, a look at the breeding industry shows that large quantities of residues are available for the raising of pigs from beans used to make soybean milk, vermicelli, and soy sauce, from grains used to make alcoholic beverages, and from fruits used to make vinegar. Slop from city restaurants and crushed canes from sugar refineries also make fine food for hogs. Many advanced representative examples have occurred showing the low cost and high benefits obtained from feeding hogs such materials. An example was in the Lojiazhuang Brigade where 365 peasant households of the Han race used the bean dregs and liquid resulting from a nearby bean products plant to feed a total of 1,432 head of hogs last year, or an average 3.9 head per household. They sold their live hogs, weighing a total of somewhat more than 134,000 jin gross weight, or an average 367 jin per household. Last year Luhua Brigade in Luhua Commune used mostly sugarbeet leaves as hog fodder to raise more than 500 hogs, or an average of almost two head per peasant household.

A good foundation already exists in suburban Yinchuan for the raising of chickens. The raising of chickens and the hatching of eggs is already being done on a fledgling scale, and some experience has been accumulated in the raising of chickens. In the urban area business network outlets are numerous; buting, selling, and transporting chicken eggs is convenient; and the breakage rate is low. Already a group of specialized households and key households for the raising of chickens has come into being. Zhi Wancai's [2535 5502 2088] chicken raising household in Lojiazhuang Third Brigade, Yinxin Commune, raised 128 laying hens that layed about 730 jin of eggs between mid-October last year and mid-February this year, which he sold for an income of more than 1,100 yuan. After deducting feed costs, net profit was more than 450 yuan, and he also had 138 mature hens, each with a value of 3.50 yuan for a value totaling 483 yuan. According to estimates from the suburban livestock and animal husbandry station, a single fine variety laying hen will produce about 20 jin of eggs. If suburban Yinchuan with its 550 production teams were to have two specialized households or key households per production team to raise chickens, each household raising about 50 laying hens, the suburban area as a whole would be able to provide virtually the approximate amount of eggs now being provided the city.

In 1978, the Manchun Brigade in Manchun Commune began to operate a milk cow farm, which now has 100 cows and produces about 300,000 jin of milk annually for net earnings of somewhat more than 20,000 yuan. At the Liangqu Tenth Brigade in Luhua Commune, Liu Shenghua [0491 3932 5478] raised 4 milk cows, which produced more than 10,000 jin of milk in somewhat more than 5 months last year for net earnings of more than 1,200 yuan. As a result, milk cow production has actively developed, another important aspect in the increase of non-staple foods to the city. Suburban Yinchuan has numerous water surfaces, having more than 8,000 mu where fish could be raised, most of which are not in use. If fully used, each mu producing 100 jin of fish, output would total between 700,000 and 800,000 jin. For this reason, active support to the development of fish raising is very necessary. Raising of sheep and goats, beef cattle, rabbits, and martens in the suburbs of Yinchuan also holds great promise.

Third, development of processing industries centering on agricultural byproducts is a major aspect of development of suburban Yinchuan commune and brigade enterprises. Right now the foundation is fairly weak in this regard, both agricultural byproduct raw materials and varieties for processing being few. Thus, it is necessary to create conditions for the processing of foodstuffs, vegetables, and livestock feeds. Once conditions have been prepared, Islamic foodstuffs such as canned goods may also be made a part of processing industries.

(3)

Conditions exist for the building of the suburbs of Yinchuan into a non-staple food production base. So how can it be built and developed? We held meetings with suburban, commune, and brigade cadres, masses of commune members and vocational department cadres among whom the consensus was that work in the following several realms should be emphasized:

1. To proceed from the necessity to build a non-staple food production base, and genuinely strengthen leadership for the development of economic diversification for early results. Use of thoroughgoing and painstaking ideological work to indoctrinate suburban cadres and the masses of commune members to make clear the major responsibilities they bear in providing the city with greater amounts of non-staple products, to overcome and reverse the emphasis of close-in communes and brigades on industrial sideline occupations while slighting vegetable production and the tendency of far-out suburban communes and enterprises to pay no attention to economic diversification in an effort to provide more vegetables, meat, poultry, eggs, and such non-staple foods to the city to make a greater contribution to the country. There is a need to fully staff and perfect management organizations and to establish personal responsibility systems, the principal comrades responsible in the suburbs, communes and brigades taking a firm grip on the task of economic diversification, clarifying duties, and devoting attention to implementation level by level. The Municipal CCP Committee and the Municipal People's Government has to consider the building of non-staple food production bases on the basis of realities, giving active financial and material support to the suburbs. All units concerned in the autonomous region and in Yinchuan Municipality should also give direction with a positive attitude, support, coordinate, help and sustain suburban communes and brigades in vigorous development of economic diversification.

2. Adhere to a program of taking the planned economy as the key link and market regulation as supplementary. There should be earliest possible action on the basis of a comprehensive survey and zoning of natural agricultural resources to readjust the structure of agriculture through the adaptation of general methods to specific situations, and to develop all-around plans for agricultural production. Currently, while maintaining a firm grip on grain production, full use should be made of natural conditions and economic resources for the active development of the breeding industry, the farming

industry, and the agricultural byproducts processing industry, particularly the development of vegetable, melon and fruit, sugarbeet, forest tree, hog, sheep and goat, dairy cattle, chicken, duck, and fish production to achieve self-sufficiency in vegetables, with gradual improvement in the self-sufficiency rate for supplies of other agricultural byproducts. Commune and brigade enterprises will have to make major efforts on the agricultural byproducts processing industry and devote any remaining resources to the operation of other industrial sideline industries. Enterprises lacking assurance that raw and processed materials can be provided or enterprises lacking markets for their products should make readjustments for gradual conversion to agricultural byproducts processing industries.

Vegetable production is an important matter bearing on the livelihood of the more than 200,000 residents of suburban Yinchuan that requires a strengthening of leadership and diligent efforts. Communes and brigades already designated to produce vegetables must persevere in making vegetable production paramount, using their major manpower, material, and financial resources on the production of vegetables to insure supplies to the city. The vegetable field area is to be maintained at its present size, and usurpation of vegetable fields for urban construction and commune and brigade enterprises is to be resolutely halted. Vegetable communes and brigades must strictly carry out state plans, individual crop planting areas and quantities being fulfilled, and sales quotas at different times and for different varieties being fulfilled. Production teams and commune members practicing the assumption of full responsibility by individual households are to resolutely carry out contracted sales tasks for vegetables. Communes, brigades, and and commune members that do not carry out plan may, in addition to being criticized and indoctrinated, have their grain rations reduced, be fined, or have other economic action taken against them. When problems arise about vegetable production responsibility systems, attention should be given investigation and study, summarization of experiences, and constant perfection of responsibility systems to solve new problems that arise and to assure that vegetable production develops in a planned way in accordance with needs.

Household livestock and poultry raising industries should promote the experiences of Lojiazhuan Brigade in Yinxin Commune, and continue to adhere to a program of walking on two legs with both collective raising and raising by individual commune members. Commune and brigade operated farms concentrating on the breeding of stud livestock and stud poultry should do a good job of breeding and hatching, actively serving commune members in developing breeding industries, placing the emphasis for breeding on commune member households. There is to be active promotion of contract systems with indoctrination of commune members in concurrent concern for the welfare of the country, the collective, and individuals, material and spiritual encouragements and rewards being given those who fulfill contracts, and indoctrination and punishment being meted out to those who do not carry out agreements.

3. Energetic development of specialized households and key households to energize the broad masses of commune members in launching economic diversification. Development of specialized households and key households

for the breeding industry and farming industry with little investment, for quick results and great benefits is a new way to hasten the building of non-staple food production bases in the suburbs of Yinchuan, and should be vigourously encouraged. The suburbs should have short-term and long-term development plans for specialized household production, and should use the signing of contracts to make specialized household production gradually become a part of commune and brigade non-staple agricultural production plans and state procurement plans. Specialized households should be permitted to use the specialized products they produce to fulfill their obligations to the state and to pay the collective various withholdings. If specialized households desire to contract the production of other items, they may, like other commune members, contract for them. If they do not want or lack resources to contract for other items, production teams may make appropriate readjustments on the masses of the scope of items being produced and individual desires so that their major energies are devoted to specialized production.

4. A good job of procurement work and keeping open procurement and marketing channels are major links in advancing the development of economic diversification. Business units are to actively support development of economic diversification and do procurement work well. In pricing policies, they are to maintain socialist business standing with no disparagement of quality in order to depress the price to be paid, or no upgrading to increase asking prices. Products not covered by agreements may be permitted to be handled as producers see fit. Effective measures should be taken to resolutely strike down and suppress "chiselers" who speculate and profiteers.

5. Active promotion of the application of science and technology to improve levels in economic diversification. At the present time suburban Yinchuan is still fairly backward in this regard and unable to meet needs for development of economic diversification. All-around processing and use of livestock feeds and fodders, breeding and promotion of fine varieties, processing, storage, and transportation of agricultural byproducts and such problems are in urgent need of solution. Thus, farm, forestry, and animal husbandry departments in the suburbs should strive to meet the new rural situation, establish personal responsibility systems, place work emphasis on the grassroots level, gear to the needs of communes, brigades, and the myriad commune member households, operate study classes and rotational training classes for specialized households and key households, and select linked households and demonstration households for a combination of representative demonstrations and wideranging propaganda, and a combination of traditional agriculture and advanced techniques, adapting general methods to local situations for the promotion of new techniques and new experiences in economic diversification. Yinchuan City and its suburbs should jointly run a vegetable research institute, and actively launch research and promote techniques for vegetable production and storage. Autonomous region and Yinchuan municipal farming, forestry, animal husbandry, and aquatic products scientific research and vocational departments should regard as part of their jobs suburban Yinchuan development of economic diversification and the building of non-staple food production bases. They should lend support and direction to suburban pilot projects and demonstrations on vegetable production and economic diversification so that science and technology blossom everywhere in the development of economic diversification in suburban Yinchuan.

BRIEFS

PROVINCIAL AGRICULTURE PROGRESS--Agricultural, industrial and sideline production in Shandong Province has made rapid progress. In 1981, the province had a grain output of 1,204 jin per mu, an increase of 260 jin per mu over 1980. Total income in 1981 was 361,600 yuan, an increase of 15,640 yuan over 1980. Per capita distribution was as high as 215 yuan, an increase of 35 yuan over 1980. Despite the drought condition this year, the province still reaped a bumper harvest of wheat. It sold 240,000 jin to the state during the first quarter of 1982, overfulfilling its quota for the entire year by over 10 percent. Per capita consumption of wheat is more than 250 jin. This is a good result of carrying out the responsibility system on a large scale. [Excerpt] [Jinan DAZHONG RIBAO 9 Aug 82 p 1]

SHANDONG WHEAT OUTPUT--Despite a continuous drought and hot dry wind and the loss of relatively large harvested areas, the wheat production in Shandong Province is better than projected. Dezhou, Liucheng, Heze, Jining and Lingyi prefectures all had increased output over 1981. The total output of wheat in the province's 123 counties, municipalities and prefectures is over 40 percent more than in 1981. More than 10 counties had a total output increase of over 30 million jin, and more than 20 counties had an average increase of over 100 jin per mu. [Excerpt] [Jinan DAZHONG RIBAO 8 Aug 82 p 1]

HARVESTING COMBINES WIDELY INTRODUCED INTO SHANGHAI SUBURBS

Beijing ZHONGGUO NONGMIN BAO in Chinese 22 Jul 82 p 1

[Article: "Suburban Shanghai Rural Villages Begin To Realize "Responsibility Systems With Mechanization. With Use of Combines, Commune Members Will No Longer Have To Do the 'Three Stoops'"]

[Text] During this year's summer harvest at Pengchao Brigade in Jiading County of suburban Shanghai, which has instituted specialized contracting in a responsibility system that links output to workforces, after taking samples to monitor output and obtaining the agreement of commune members, two combines were brought in. In less than half a day's time, harvesting and threshing were finished, and after weighing the grain on the spot and converting to dry grain equivalent weight, yields were found to average 544 jin per mu, 50 percent more than last year. Commune members said joyously, "Formerly it was the 'three stoops' that were most tiring, but now harvesting and threshing are all done at once, and we want this kind of responsibility system with mechanization!"

"Responsibility system with mechanization" is the common cherished desire of the broad masses of Shanghai suburban peasants. Since the Third Plenary Session of the 11th Party Central Committee, accompanying the all around development of agricultural sideline occupations has been a net decrease in agricultural workforces. Last year net agricultural workforces in Shanghai's suburbs amounted to only 56.4 percent of total available workforces, and 62.1 percent of these were female members of the workforce. Though each person is responsible for the farming of an average of only slightly more than 3 mu, the multiple cropping index is as high as 240 percent. Peasants who practice the linking of output to workforces generally reflect the intensity of labor when they say, "Responsibility systems are fine indeed, but the exertion is sometimes hard to take."

Practice has made leaders at all levels in suburban Shanghai come to the realization that general mechanization on a foundation of responsiblity systems is both a necessity in continued maintenance of the fine tradition of intensive farming and a necessity for stabilizing and perfecting agricultural production responsibility systems. It was for this reason that they actively ran pilot projects at Malu Commune in Jiading County and at Lodian Commune in Baoshan County. Beginning last year, they used accumulations from agriculture itself for the large-scale introduction of combines, which are most needed in agriculture and which reduce labor intensiveness most strikingly. As of this spring, 10 counties in the prefecture had introduced 362 combines for an average of 2 per commune. When these harvesting combines were used in conjunction with existing machinery, the intensity of commune member labor during the very busy season was greatly reduced, and the "foot dragging fields," and "tail end fields" that dragged out the farming season were eliminated.

The practice of a "responsibility system with mechanization" in Shanghai's suburbs has already demonstrated its superiority in three regards. One is promotion of the stability and perfection of responsibility systems. In some production teams practicing the linking of planned output to workforces, the conflict among individual households during the harvesting season for use of threshing grounds and threshing machines had been very pronounced. But with harvesting combines, the real strength of the collective has been increased. Everything that lends itself to centralization is centralized, and production team heads no longer need to have "headaches" about arrangements for use of threshing grounds and threshing machines. For some production teams in which responsibility systems could not be instituted because of the large amount of land relative to population, through the boost that mechanization has provided, responsibility systems have been very quickly instituted. A second is promotion of a beneficial cycle in agricultural sideline industires and their coordinated development. Agriculture can steadily support industrial sideline occupations with workforces, and industrial sideline occupations can, in turn, steadily provide agriculture with accumulations of funds. The path of coordinated development of agricultural sideline industries becomes wider and wider. Third is a fundamental reversal in the trend toward departure from agriculture. Commune members say happily that with an increase in mechanization, the 'three stoops' have been solved. Working the fields is more or less like working a factory, and we have no desire to go into enterprise units. Today in Lodian Commune, Baoshan County, where the largest number of combines have been introduced, the "extremely busy season is not busy," and commune members who farm go to movies as usual, their per capita distributions averaging 350 yuan, not much different from commune members who are engaged in industry. As a result, they are universally content to farm.

BRIEFS

RAINFALL IN SICHUAN BASIN--Beginning on 15 August, heavy and torrential rains have fallen on the western part of the Sichuan Basin, including Wenjiang, Leshan, Yaan and Mianyang Prefectures and Chengdu Municipality. These torrential rains centered around Shifang, Xinjin, Shuangliu, Qionglai, Pengshan, Renshou, Leshan and Jingyan counties. Up to 1600 on the 16th, 42 counties had received over 50 millimeters of rain. Among them, 14 counties had 100-264 millimeters of rain, and Renshou County's (Gongnongchuan) had the most rain--264 millimeters. This time, the rains fell over a vast area and with relatively great intensity. In Rongxian County's (Xinqiao), 88 millimeters of rain fell in 2 hours and 136 millimeters in 6 hours. The water levels of the Minjiang, Tuojiang, Qingyijiang and Fujiang Rivers are rising. The water levels of the Minjiang and Qingyijiang have already exceeded the warning marks. At present, the flood season is not yet over. All localities should do a good job in guarding against floods and controlling water. NEW-STYLE ECONOMIC COMBINES DISCUSSED

HK160327 Kunming YUNNAN RIBAO in Chinese 2 Aug 82 p 2

["Work Research" column by Zheng Yanshi [6774 6056 1395]: "Correctly Understand and View the New-Style Economic Combines"]

[Text] In the development of the production responsibility systems in rural areas, especially in those areas where the system of assigning households full responsibility for task completion has been practiced, a new trend of economic combination has appeared among the commune members. This kind of economic combination takes various forms. There are combinations or certain production elements, certain production links and certain production (or business) items. Some of them are temporary and some are relatively regular. There are multibrigade and multicommune combinations and combinations of commune members and residents in towns and cities. A peasant household may be engaged in several combinations at a time. The emergence of these new economic combinations taking various forms has added new vitality to the enlivened rural economy.

These activities of economic combination, which are extensive and varied, have naturally given rise to a number of new-style economic combines, which are economic entities relatively independent of the collective economy of the communes and brigades and are voluntarily and freely established by commune members with the participation of several households. The funds for these combines are collected and the equipment purchased all by the participants themselves. They work together, carry out independent accounting and assume sole responsibility for their profits and losses. For example, three commune members, (later developed to five households and nine laborers) Deng Liangshi, Tao Renbin and Wang Bangming in the Taojiawan production team of the Haozhi brigade, Xinglong commune, Yanjin County, each of whom collected and contributed 30 yuan, jointly run a small factory to produce flues, which are used in producing flue-cured tobacco. Since it went into operation last November to the end of May this year, it has gained an income of 8,015 yuan by selling 17,000 of its products. After deducting 2,856 yuan for accumulation and production costs, 5,159 yuan was distributed among the participants. On average, each participant created a value of 4.3 yuan on each working day. Such economic combines have now appeared everywhere.

At present, since the new-style economic combines are still at their initial stage, they are small, scattered and unstable. Most of their businesses are within the range of industrial and sideline production, having a purpose of serving agricultural production (including the diversified economy) and the livelihood of the masses in their localities.

As soon as these economic combines came into being, they displayed their advantages. They were vividly summed up by the masses of people who said that in these combines, "shares are bought voluntarily and suggestions are made by all. Work is done well and the management is good. The products are marketable and distribution is made according to work." These economic combines are usually small and flexible. They often do things in a simple and thrifty way, using available local resources. Since the economic makeup and management methods are simple, the investment is usually small but economic returns are quick and economic benefits are more direct. The members of the economic combines are owners of these combines and at the same time, managers and laborers. There are no such problems as "eating out of the same big pot" or the "iron rice bowl," and every participant has to work hard. Thus better economic results are usually achieved.

The economic combines are advantageous to making full use of natural and manpower resources and idle funds so that they can be changed into new productive forces. They are also advantageous to giving full play to the roles of skilled craftsmen so that the technological level in the countryside can be raised under their guidance. They are good for the development of the diversified economy and commodity production in the light of the local conditions so that the rural economy can be stimulated and the peasants' livelihood can be improved. They can satisfy some of the pressing demands of the masses in their present production and livelihood and promote the future development of the rural economy along the orientation of specialization and socialization.

On the other hand, we must also recognize that since these combines are only a kind of economic organization which is collectively owned and jointly run by a small number of peasants, they usually concentrate their attention on their partial and immediate interests and put profit-making first. Blindness in production and business can easily occur. Sometimes, they may even sabotage state planning and damage the interests of the state and the interests of communes and brigades. If leadership is not exercised over them, they may easily rush headlong into action, disperse in a hubbub and perish of themselves. These are limitations and shortcomings of the economic combines.

The emergence of the new-style economic combines after practicing the system of assigning households full responsibility for task completion was not a chance phenomenon. It is an example showing the emancipation of productive force since the great readjustment of production relations in the countryside. After the system of assigning households full responsibility for task completion was practiced in many production teams, the commune members felt that they "had enough food to eat, but had not enough money to spend." They became anxious to develop a diversified economy so that the surplus labor could find a way out and they could gradually become well-off. However, since many businesses cannot be run individually or by only one household, the new-style economic combines, which are called "gathering together in business" by the masses, have emerged as the times require. This is a result of the role of the objective economic law which requires that production relations suit the development of productive forces. It is also a concrete expression of the creativeness of the masses of peasants.

The new-style economic combines are new things which have emerged at present in the countryside. They have posed a series of new theoretical and practical problems which need to be studied and solved. What is our correct attitude in understanding and viewing these problems? We would like to offer our following initial opinions.

1. The new-style economic combines among the commune members are new economic formations which are collectively owned and jointly run by the laboring masses. They are a new component part of the socialist collective economy in the countryside. Therefore, we must encourage, guide and help them to develop and must adopt a policy of enlivening these combines so that they will play an active role in the development of the rural economy.

2. While encouraging the development of the new-style economic combines, the commune and brigade economies must not be neglected or weakened. It is necessary to forcefully help the communes and brigades run collective industrial and sideline enterprises well and prevent the new-style economic combines from damaging the collective economies of communes and brigades through appropriating or purchasing commune and brigade property at a low price.

3. In principle, the new-style economic combines and commune and brigade enterprises must be equally treated in terms of rights and duties, such as tax payment and loans. When the economic combines need to use state and collective material resources, they must be charged necessary fees. Sabotaging the material resources of the state and the collectives is not allowed. Besides, it is also necessary to handle well the relations between the economic combines and individual producers in rural areas, preventing the trend of merely encouraging individual producers and restricting economic combines. We must let them have equal opportunity to develop and give play to their advantages.

4. Referring to leadership system, the new-style economic combines among the commune members must be under the leadership of the local government. Before government administration and commune management are separated, communes and brigades in the respective localities must take charge of the leadership work. The administrative departments of the commune or brigade enterprises at various levels must, according to the requirements of the relevant documents of the provincial people's government, take the work of the economic combines as their own work and give them concrete guidance. They are required to help the economic combines overcome difficulties in production, supply and marketing, improve their management and constantly improve their processing techniques with local resources so that the diversified economy in the countryside can be further developed. They must help

them produce more inexpensive and good commodities, tap new sources, open up new markets and improve their service so that their economic forces can be gradually expanded and the range and quality of their production can be developed. It is necessary to strengthen the ideological and political work and make the combines abide by state policies and decrees, accept the guidance of state planning, give consideration to the interests of the state, the collective and individuals and distribute according to one's work. It is also necessary to give guidance to their arrangements and economic activities by means of various economic levers and contract systems so that such things as duplication of the same trade can be avoided and the economic combines can develop healthily along a correct path.

BRIEFS

FERTILIZER SHORTAGE--Participants to a recent provincial conference on fertilizer work made some recommendations on solving the current fertilizer shortage for Zhejiang's late rice crops. They noted that organic fertilizer is about one-third short and that the supply of chemical fertilizer is also less than last year. They suggested that every peasant household should accumulate organic fertilizer and that chemical fertilizer should be used rationally. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 10 Jul 82]

FEED INDUSTRY--The Zhejiang Provincial Food Department recently held a province-wide conference on the feed industry. From 1979 to 1981 the province made arrangements for the construction of 40 feed processing plants. As of now, 25 of them have been completed and put into operation. And 14 others will be put into production in the near future. About 29 million jin of mixed feed were produced in 1979 throughout the province, but the output rose to 400 million jin in 1981. The provincial people's government has drawn up a plan for building 120 feed processing plants within the next 3 years. [Hangzhou Zhejiang Provincial Service in Mandarin 1030 GMT 1 Jul 82]

TITLE: "On the Relationship Between Changes of Ecological Condition in Shanghai Suburbs and the Yield Reduction of Cotton"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 4, 5 Aug 82 pp 1-4

ABSTRACT: Since the unit yield of cotton of the 1.40 million mu of cotton acreage of Shanghai suburbs successfully reached over 100 jin in 1964, the yield has been high but not stable, varying from 169 jin of 1978 to 91 jin of 1977 historically and from the 198 jin of the highest county to the 56 jin of the lowest county geographically. Following an analysis of the conditions of land, rainfall, temperature, daylight, typhoon, diseases, and pests, the paper concludes that of all the ecological conditions, the effect of the weather condition is the greatest. A mathematical model: $\hat{y} = (x + \Delta x) \times (1 - \eta)$ to demonstrate the relationship between the yield potential $(x + \Delta x)$ of a given year and the rate of yield reduction due to unfavorable ecological factors (η) is explained. Finally, the paper proposes the 3 measures of increasing the layer of mature topsoil to 20-25 cm to promote root development, improving drainage to activate soil fertility, and encouraging early development to increase the weight of cotton bolls, to counter the variable ecological conditions.

TITLE: "Actively Help Commune Members Manage and Use Private Mountains Well"

SOURCE: Beijing ZHONGGUO LINYE [FORESTRY IN CHINA] in Chinese No 7, 17 Jul 82 pp 13-14

ABSTRACT: Last year, the Laiwu County Committee and government of Shandong Province issued forest rights certificates at an assembly of all the county's 15 communes (towns). It is clearly stipulated on the certificate that the private mountain is owned by the collective body and its sale, lease, and transfer are not permitted. It may only be used for afforestation or raising saplings and cultivation of anything else is not allowed. Trees planted by a commune member belong to that member perpetually and his sons and daughters will be permitted to inherit them. Forests of private mountains are protected by the law same as those belonging to the State and collectives. These certificates removed the worries of those members who contributed saplings, money, and labor to afforest those mountains. The county has 900 thousand mu of land suitable for afforestation; of these 710 thousand mu were managed by communes and brigades. Last year, all this acreage was readjusted and 387 thousand mu of which that had better trees were retained by the brigades and 184 thousand mu of which that were not in very good condition were given to the production teams which in turn divided 138 thousand mu to the 53 thousand memberhousehoods. These private mountains given to the members were all barren. After

[continuation of ZHONGGUO LINYE No 7, 1982 pp 13-14]

this readjustment, the key problem was to help the commune members to do a good job of afforesting these barren mountains, which amounted to 19 percent of all the land of the county suitable for growing trees. Aside from issuing certificates to ease the mind of the members, the county provided 2 million saplings, set the standard of land preparation and planting quality, and organized for guidance and inspection. These measures proved to be very effective, and so far 75 thousand mu of the 138 thousand mu of private mountains have been prepared and 51 thousand trees have been planted. The successful afforestation project in Laiwu County of Shandong Province is reported in the paper.

TITLE: "An Effective Way of Late Rice Breeding-- Sub-Xian-Geng Hybrids"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 8, Aug 82 pp 1-3

ABSTRACT: After many years of repeated exploration and practice, the authors have summarized and found 2 effective ways of hybridization to breed late rice: the sub-xian-geng hybridization method and the method of interspecific hybridization of varieties of different ecological types. This paper reports the first of the two only. Since 1972, the authors have successfully experimented with the technique of crossing breeds containing Xian and Geng cytoplasm first before crossing the hybrid with either Geng or Xian to overcome the problem of sterility of F1 and F_2 Xian-Geng hybrids. With this technique, from the initial crossing to stabilization, 6 generations are sufficient to produce a new breed. For the convenience of expression, the authors call this type of new breeds, sub-xian-geng. With this technique, the sources for hybridization are greatly enlarged and the current problem of narrow genetic foundation of late rice hybrids may be resolved. Problems still exist with respect to selection of the hybrid offsprings, however, and it remains a difficult task to breed out ideal new varieties having the merits of both Xian and Geng types.

TITLE: "Expressions and Selection of F_2, F_3 of Triticale-Wheat Hybrids"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 8, Aug 82 pp 4-8

ABSTRACT: The author and colleagues have reported in a previous paper that according to their observation in 1980, the F_1 of triticale-wheat hybridization is sterile when paper bags are used to insure self-fertilization, but when it is left open for free fertilization, it will fruit to expand the genetic foundation. In 1979-81, hybrid offsprings of triticale-wheat were again left to proceed with free pollination, fruiting, and segregation and in some cases the hybrid offsprings were purposefully backcrossed and selected for the purpose of observing the expressions and the results of selection. Such expressions as disease resistance, high yield property, maturization period, fruiting rate, etc. are described.

ORG: Huanggang Prefecture Research Institute of Agricultural Sciences

TITLE: "An Analysis of Wheat Breeds Used in Huanggang Prefecture"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCE] in Chinese No 8, Aug 82 pp 9-11

ABSTRACT: In a normal year, the wheat acreage in Huanggang is about 2.5 million mu. In the 33 years since the liberation, with the changes of production condition and the development of productivity, there have been 2 major events in the use of wheat breeds in the prefecture: the extension of Nanda-2419 in 1956 and the extension of Omai No 6 in 1974; both brought important yield increases. In 1979, the average yield of the prefecture reached as high as 360 jin/mu. There have been yield decreases in the past 2 years, however, due to severe powdery mildew of Omai No 6 and serious degeneration of seeds. The high incidence of rust and powdery mildew and the attempt of obtaining high yield from both crops of cotton and wheat dictate the need of using dwarf wheat breeds that are more fertilizer tolerant and lodging resistant than Omai No 6, which is urgently in need of revitalization. Moreover, all the wheat breeds currently being extended in the prefecture, such as Omai No 6, 48130, 69-13-3, 2133, 31761, etc. are all related to Italian wheat. The genetic foundation is narrow and disease resistant genes are not sufficiently rich. Expanding the breed resources is very important if the yield of wheat in the prefecture is to improve.

AUTHOR: YU Zheng [0151 1513]

ORG: Shaanxi Provincial Science and Technology Committee

TITLE: "Opinions Concerning the Soil and Water Conservation Work in Northern Shaanxi"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 1-5

ABSTRACT: Soil loss due to erosion is extremely severe in the loessial plateau of northern Shaanxi, affecting an area of 67 thousand km^2, amounting to 81.9 percent of the total area of northern Shaanxi. The soil erosion modulus reaches 10 thousand tons/$km^2 \cdot$ year. Every year, as much as 6.7 hundred million tons of sand flows into Huanghe from this region, amounting to more than 40 percent of the added silt in that river. The resultant thin soil and drought cause the level of agricultural production of the region to be low and unstable to form a drag on the economic development of the province and to cause the river to be more and more a threat to the lives and properties of its lower reaches. From 1954 to 1980, 8 billion yuan was spent on soil and water conservation of this region, not including afforestation. Many dikes have been built, washed away, and rebuilt and about 3.5 million mu of fields have been terraced, etc. Some believe these projects have not reduced the amount of sand going into Huanghe. This is obviously the result of the destruction of forest and the inferior quality of some engineering structures, but the

[continuation of SHUITU BAOCHI TONGBAO No 3, 1982 pp 1-5]

very fact that the sand content of Huanghe has not been increasing is a great achievement of these works. Others maintain that the cultivated acreage must be preserved to guarantee the yield of grains and are against the attempt of restoring the forest vegetation. They do not understand that the most reliable way of establishing a new ecological balance to resolve the problem of grain shortage is to practice a combination of farming, forestry, and animal husbandry. The paper seeks to justify soil and water conservation projects as well as to explain in detail the scientific and reasonable ways of proceeding with future conservation projects.

AUTHOR: HE Yubang [6320 3768 6721]

ORG: Shaanxi Provincial Bureau of Water and Soil Conservation

TITLE: "Major Factors for Speeding Up [Erosion] Control"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 6-12

ABSTRACT: Since the liberation, erosion control has been carried out over 35.2 thousand km^2 in Shaanxi, amounting to 25.6 percent of the area suffering from soil and water loss, and averaging a speed of control of 1 percent/year. Construction of terraced, diked, raised, and sandbank fields was complete for 11.43 million mu, amounting to 25.9 percent of the province's slope land and the average speed is also only 1 percent per year. Due to various reasons, serious soil and water conservation work was carried out in only 15 of these 30+ years, in areas of more than 1,000 km^2 per year. In these 15 years, work was done in 2,000 km^2 in 10 years and 2,500 km^2 in 5-6 years. Thus, only in 7 years, the area of control amounted to more than 1.5 percent of the area of erosion and more than 2 percent in 3 years only. The best years were 1972-73, with 2.7 and 2.3 percent respectively. The average progress of the 50's is 1.3 percent; of the 60's 0.8 percent, of the 70's 1.1 percent, of the 80's 2 percent, to indicate a general tendency of fast-slow-fast. The speed of erosion control in the province must be quickened. It is entirely possible to deal with 2,800-3,200 km^2 per year to eliminate erosion in the province in 25 to 30 years. A good way of doing this is to control small drainage basins first and to combine the use of vegetation with engineering projects, with more than 60 percent emphasis on the former.

TITLE: "Report of An Inspection Tour of Parts of the Changjiang Valley in Southern Shaanxi"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 12-17

ABSTRACT: Following the flood disaster of 1981 in western Sichuan and southern Shaanxi, the problem of preventing Changjiang from becoming the second Huanghe has been the concern of all the peoples of the country. The National Agricultural Committee ordered the Changjiang Valley Planning Office to dispatch specialists, professors, and scientists to carry out comprehensive surveys in 4 teams for Yunnan and Guizhou, Hunan and Jiangxi, Hubei, Henan, and Anhui, and Shaanxi, Gansu, and Sichuan. This paper reports the portion of the survey carried out by the 4th team in 29 counties of southern Shaanxi, covering an area of 74 thousand km^2. Flood and erosion damages observed by the team are detailed. The paper also discusses the causes of the disaster and suggests water and soil conservation measures for reconstructing the region and for preventing further erosion.

ORG: Shaanxi Provincial Bureau of Water and Soil Conservation

TITLE: "A Survey of the Disastrous Flood in South Shaanxi in 1981"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 21-25

ABSTRACT: In Jul and Aug 81, there were continuous heavy rains in the southern parts of Shaanxi to cause gigantic damages from floods, mudslides, landslips, rock flows the mountainous and plain regions alike. The area of southern Shaanxi has had frequent floods in recent years. The prolonged high volume autumn rains are the direct cause, but there are also the problems of lack of unified planing for controlling the rivers, the poor quality of the engineering structures, etc. Judging from the macrophenomenon, the abusive destruction of forest vegetation to create cropland is the important factor leading to the increasing severity of erosion and flood calamities. The paper summarizes the natural factors contributing to soil and water loss of the area, namely the water, the soil parent material,and the slanted terrain,and the human factors which exacerbate the situation, namely cultivating crops on steep slopes, destroying water nourishing forests, constructing plants, roads, and mines without considering water and soil conservation, etc. Some basic and comprehensive measures of water and soil conservation are proposed as the fundamental method for reducing drought and flood damages.

TITLE: "The Function of Forests in Controlling and Conserving Water"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 54-56, inside back cover

ABSTRACT: Heavy rains fell in Feng and Taibai counties in the period 14-22 Aug 81 to produce the greatest flood disaster in the history of that region. By 28 Aug, dozens of persons were killed and several were still missing. The homes of more than 20 thousand were lost, and 100 thousand mu of the 280 thousand mu of cropland in Feng County were totally destroyed, in addition to the damages to railroads, highways, bridges, power transmission lines, dams, factories, dormitories, hospitals, schools, etc. This was a cruel punishment inflicted by nature on the people of China for destroying the forest vegetation and converting the land into mines, roads, and fields. The water controlling and conserving action of forests cannot be replaced by crop plants and engineering structures. This paper explains the water controlling and conserving action of forests in some detail. The paper also suggests enactment and strict enforcement of laws to protect forests.

MINISTRY OFFICIAL EMPHASIZES IMPORTANCE OF AUTUMN HARVEST

Beijing ZHONGGUO NONGMIN BAO in Chinese 8 Jul 82 p 1

[Article: "Work Ceaselessly and Unremittingly To Win a Bumper Agricultural Harvest for the Year as a Whole. Ministry of Agriculture, Animal Husbandry, and Fishery Responsibile Person Makes Statement to Newspaper's Reporter"]

[Text] Now the summer harvest is in, and the fall crops are at a crucial time in their growth. How to work ceaselessly and unremittingly to win a bumper harvest for the year as a whole, and to fulfill quotas for increased agricultural output for the year as a whole is a problem that concerns all. A responsible person in the Ministry of Agriculture, Animal Husbandry, and Fishery made a statement on this subject to the newspaper's reporter as follows:

Despite the natural disasters of severe drought and hot dry winds that beset the country's agricultural production during the first half of this year, thanks to the broad masses of rural villages having assiduously carried out CCP Committee Document No 1 for the further implementation and perfection of agricultural production responsibility systems, a fine grain and oil-bearing crop harvest was realized. A look at actual circumstances shows the summer grain crop to have been better than anticipated, with total output nationally approaching last year's levels. Jiangsu, Anhui, Sichuan, Hubei, Zhejiang, Shanghai, Shaanxi, and Gansu all had increased output; Hebei and Henan had either the same or slightly decreased outputs. Output to rapeseeds went on from 3 consecutive years of bumper harvests to reach an all-time high. Spring and summer sown crops were planted earlier than last year, and in North China autumn-harvested crops grew rather well. In South China, early and intermediate rice grew better than last year. Economic crops such as cotton, soybeans, and peanuts grew better than last year.

However, since the beginning of June, rainfall has been early and fairly concentrated in South China, and in some places torrential rains have caused disasters, badly hurting the early rice crop. In some parts of North China summer drought advanced, and in still other places disease and insect pest infestations have been very serious. Consequently, the urgent task that now confronts us is further carrying into effect of the program of "positively no relaxation in grain production while actively developing economic diversification," going all out, working ceaselessly and unremittingly, further stabilizing production responsibility systems, more fully stirring the enthusiasm of the broad masses of cadres and people, devoting intense attention to field care of crops to be harvested in the fall, working hard during July, August, and September, using every available means to win a bumper harvest for the year as a whole and striving to fulfill increased in production quotas for the year as a whole. In order to do this, it is necessary right now to give attention to efforts of the following several kinds:

1. Further Mental Arousal. Autumn is the main season in agricultural production in China, both the area planted to fall grain and output amounting to two-thirds the annual total, the economic crops being harvested mostly in the fall as well. During the past 10 years, summer grain production has developed fairly rapidly and consistently for an average annual incremental increase of 5.9 percent, while the annual incremental increase for autumn harvested grain crops has averaged only 2.1 percent. Autumn grain production is low and inconsistent, impairing the speed of agricultural development. This year's state plan calls for a grain output increase over last year of more than 17 billion jin. Inasmuch as the summer grain harvest did not reach target goals, autumn grain output quotas have been increased. In present terms, fulfillment of this quota will be conditional upon the following: First is high enthusiasm on the part of the masses, and second is a good fall crop growth in most places. In the time remaining, only if the right actions are taken can output from the autumn harvested crops hold great prospects. All jurisdictions are to clearly explain to the broad masses the importance and the arduousness of winning a bumper harvest for the year as a whole so as to overcome the blind optimism and lackadaisical feelings that exist in some places, to direct the enthusiasm of the cadres and masses to taking a firm grip on autumn production to win a bumper harvest for the year as a whole.

2. Take Firm Hold on Crucial Actions to Increase Output. Good planting is the foundation, and care is the key. Practice has shown that care or no care makes a big difference. With good care, weak seedlings become sturdy seedlings, and sturdy seedlings become more sturdy. With poor care, good seedlings become poor seedlings. The principle of adaptation of general methods to local situations has to be followed using tailored guidance to carry out scientific care that is pertinent. In South China, efforts must be continued to be directed toward late stage care of early rice, and to mid and late stage care of intermediate rice and cotton. Additionally, it is necessary to do a good preparatory job for late rice in a two crop system in an effort to win new breakthroughs from late rice. The area planted to early and late rice is more or less equal for the country as a whole, yet total output from the late rice crop is more than 2 billion jin less, largely because of late transplanting, insufficient fertilization, and much damage from diseases and insect pests. This year all jurisdictions are to focus on problems existing in late rice crop production and increase measures taken to strive for high and consistent yields. In North China

it is necessary to educate a small number of cadres and masses in the need to overcome their mentality of "emphasizing the summer and slighting the fall;" in addition to devoting attention to the spring sowing of grain and cotton crops, they must also take firmly in hand late autumn crop production. As a result of the severe drought during the previous period, growth of late autumn crops has been particularly uneven; consequently, major efforts have to be made to provide early and intensive care to bring early ripening so as to prevent or avoid early frost damage.

3. Vigorous Launching of Technical Service Work. Following the institution of production responsibility systems, in order to win high yields, among the broad masses of peasants everywhere a craze for studying science and using science appeared. Agricultural departments everywhere should vigorously launch technical service work, further implement and develop technical contract agreements, establish technical consulting sites, train peasant technical personnel, arrange peasant household scientific farming demonstrations, and print technical materials to get into the hands of the myriad peasant households effective measures for increasing yields as well as scientific techniques. Farm technical personnel should not only operate at key points but should also promote work over a wide area to promote increased yields over a wide area.

4. Take a Firm Grip on Production in Medium and Low Yield Areas. The area of China sown to spring and summer crops is more than 1 billion mu. With the exception of a portion that contains high yield fields, a considerable part of this area is medium and low yield fields. Practice has shown that the potential in this part is very great. In addition to giving attention to making high yield fields into mainstay fields with increased yields, all jurisdictions are to devote efforts to medium and low yield fields, intensify care, and direct the main attack against yields per unit of area to promote even production.

5. Make a Stand on Resistance to Disasters to Win a Bumper Harvest. It is during the growth period for autumn harvested crops that damage from various natural disasters is most frequent; thus, it is necessary to stand fast against disasters to win a bumper harvest. Weather forecasts for mid-summer this year call for an overly large amount of rain in the upper reaches of the Chang Jiang, in the Huai He Basin, and in the lower reaches of the Huang He, with flooding and waterlogging occuring in some places. In North China and Northeast China, rainfall will be less than usual, the drought continuing. In some parts of the area south of the Chang Jiang, summer drought may occur. Thus, it is necessary to make multiple preparations to prevent or combat disaster mentally, with actions to be taken, and with materials to be used, as well as to bolster monitoring and forecasting of diseases and insect pests in an effort to reduce to the minimum damage caused by natural disasters. In places where summer grain yields are reduced by disasters, in particular, full preparations should be made to combat disastesr to win a bumper harvest for the year as a whole so that the autumn harvest will make up for the summer harvest.

6. Strengthening of Leadership. During the period when a bumper autumn harvest is being harvested, there is much farm work to be done and time is short. In rural villages, organizations at all levels must strengthen leadership and make overall arrangements to take firmly in hand as the central task in rural villages the winning of a bumper harvest for the year as a whole. All levels of agricultural departments should diligently change their workstyles, go down into the grassroots levels, investigate and study, give attention to providing for the livelihood of the masses, and promptly report to units concerned problems existing in production such as shortages of fuel, electricity and needed fertilizer, and win the support for agriculture of all trades and industries in order to make a contribution to the reaping of a bumper harvest for the year as a whole.

There is still some time before the autumn harvest, and the room for maneuver is still very great. If only our mentalities are emancipated and we take a firm grip on each production link, do a solid job of field care, taking hold of every link and holding fast to it, we will be able to do a good job of autumn production and win a bumper harvest in agriculture for the year as a whole.

CRUCIAL IMPORTANCE OF SCIENTIFIC FARMING UNDERLINED

Beijing ZHONGGUO NONGMIN BAO in Chinese 11 Jul 82 p 1

[Article by Yao Yilin [1202 0181 2651]: "Vigorously Raise Levels of Agricultural Science and Technology for In-depth and In-Breadth Progress in Production"]

[Text] Development of China's agriculture has to rely on policies and on science. The policies that have followed from the Third Plenary Session of the 11th Party Central Committee will continue to play a role for many years to come. Likewise, agricultural production's reliance on science will also be placed on daily agendas in greater scope.

In longrange terms, development of agriculture requires planning that is national in character. Planning must be done for the long range, the medium long range and the short range. The long range is from 50 to 100 years, with things like the building of the loess highlands taking quite a long time. Medium long range means 20 years or until the end of this century. Short range means 5 to 10 years. Long range planning is for the purpose of resolving our goals. Short-range plans are for the purpose of clarifying how we can begin, doing the easy first and the difficult later, first eating the "meat," and later gnawing on the "bones," studying what can be obtained first and put to use to take the next step. Planning has to be done in an overall way and carried out little by little and place by place; there can be no equal use of forces at the same time in all places. To do otherwise would require too much investment, a long period of time, no immediate results, and no turnover of financial and material resources.

Agriculture is the foundation of the national economy, and development of agriculture is, at bottom, the premier problem in China's national economic work. Output value of China's industry has long since stood at about 70 percent of the total output value of industry and agriculture combined, yet 80 percent of the country's population lives in rural villages. The status of the development of agriculture is a major matter bearing on the overall situation. Between 1979 and 1981, the total output value of China's agriculture grew 18 percent, with every peasant averaging a 66 percent increase in earnings. This has been the golden age in development of China's agriculture. However, it has to be realized that at the present time our agricultural production is fundamentally a hand operation, with both the labor productivity rate and the agricultural products commodity rate being relatively low. Capabilities for withstanding natural calamities are weak, and the contradiction between population increase and a lack of land becomes ever more prominent. The current struggle between economic crops and grain crops for a growing area is one manifestation of this contradiction. Consequently, while adhering to control of population increase, we must make advances in depth and in breadth in production, so as to produce from limited land an ever increasing amount of grain crops, economic crops, and other agricultural by-products.

Full use must be made of the land. So long as soil and water conservation and the ecological environment are not hurt, good use should be made of barren mountains and seacoast flats to increase the forest cover rate. There should be gradual improvement in production conditions such as seed and soil improvement, the composition of fertilizer and fertilization methods, farmland capital construction, farm machine improvements, etc. In addition, grain production and economic diversification should be properly linked. In this country of ours, the grain problem, or rather the food problem, is always a very big problem because of our 1 billion population. For a long time we have been in a situation of a low standard "melon and vegetable era," and some people do not realize the seriousness of this problem. However, for genuine improvement in the quality of people's lives, the food problem is always a conspicuous problem. Of course improvement in food does not necessarily mean to eat meat. Today some people advocate a change in the meat eating road that Europe and the Americas have taken to the use of plants to make plant protein. They have discovered that to have plants eat grain with people then eating the meat means waste of quite a bit of protein. Getting protein directly from the plants to make protein foods rich in amino acids is alway to save protein. In China's traditional diet, an overwhelming majority of people eat mostly grain. Therefore, for a fairly long time to time, China's agricultural structure will continue to stress grain production, and the grain growing area has to be suitably stabilized. Grain production has to be used to assure economic diversification, and economic diversification has to be used to advance grain production, with adaptation of general methods to local situations and equitable zoning for coordinated development of both.

In order to realize the aforestated goals, the scientific and technical level of farm science and technology personnel and the cultural and technical level of workers must be raised. A look at foreign experiences and our own experiences shows that when workers' cultural levels are high, labor efficiency is high, sensible suggestions become numerous, and work creativity also becomes greater. Some economically advanced countries rely to a very great degree on advance in science and technology to bring about improvement in the labor productivity rate. Consequently, an intensification of cultural education and scientific and technical education in China's rural villages is an extremely important problem that cannot be ignored. In a certain sense, the investment in cultural knowledge is more important than the investment in material resources.

Comrades who have been engaged for a long time in scientific and technical work in rural villages have gone through great hardships, and both the party and government should cherish them and gradually make good arrangements for their work and their daily lives. What the broad masses of science and technology workers and the broad masses of intellectuals want, first of all, is the party's confidence in them so they can make the most of their work skills and contribute their luster and ardor. Implementation of policies on intellectuals requires that work be done in this regard first of all. Everyone also seeks improvement in his livelihoods. The lives of middle aged intellectuals is particularly hard. They are, however, able to make allowances for the country's straitened circumstances and not demand that improvements be made at once, but rather than improvements take place gradually over a period of time. Wartime hardships were much greater than now, and did the intellectuals not persevere in struggle under the leadership of the party? Today the situation is much better than during wartime. Of course several years time will be necessary to bring about gradual improvements in their livelihoods so that they will be free from nagging worries while they do their work, and will have the necessary material conditions enabling them to make most use of their intelligence and wisdom in the course of modernizing agriculture.

NATIONAL

INDUSTRIAL, AGRICULTURAL PRICE RATIOS EXPLAINED

Beijing BEIJING RIBAO in Chinese 12 Mar 82 p 3

[Article by He Cun [4421 2625]: "Increase in Peasant Earnings Cannot Again Come From Increases in Procurement Prices"]

[Text] Increase in peasant income and steady improvement in the people's lives is, without doubt, a major matter about which the party and state are regularly concerned. It is also a required goal of socialist production. Nevertheless, the fundamental way in which to increase peasant income and improve the lives of the people is development of agricultural production and increasing national wealth, not reliance on steady increases in procurement prices paid for agricultural products. This is because, to do this would be extremely disadvantageous for both peasants and the country alike.

We know that price is an expression of value in monetary terms. Prices fluctuate according to value, and this is a manifestation of the role of value laws. However, when prices are at variance with value, being overly high or overly low, the national economy be damaged, with the result that workers or some workers sustain losses. The economic depressions, the market slumps, and the inflation of old China caused the broad masses of workers serious damage. Ours is a planned socialist economy in which full advantage may be taken of the superiority of the planned socialist economy, and the laws of value used to serve the planned economy. Through the use of planned controls and market regulations, the state can stabilize the prices of goods at a specific level within a period of time. This is not only advantageous for the development of production and gradual improvement in the livelihood of the people, but is of major significance in consolidating the alliance of workers and peasants, and in promoting the stability and unity of all the nationalities in the country. Consequently, in a situation in which no substantial growth can occur in industrial or agricultural goods, there is no use hoping for continued increases in purchase prices paid for farm products to increase peasant income. Under current circumstances in which the public coffers are still running a deficit, in particular, further increases in purchase prices paid for farm products must inevitably entail the issuance of more banknotes, increasing the amount of currency in circulation and increasing the purchasing power of society, thereby artificially creating a market shortage of supplies. Furthermore, to continue along these lines, this would lead inexorably to inflation. When that happened, the money that the peasants gained from increases in purchase prices would be entirely lost in buying industrial goods, and would consequently be like drawing water with a bomboo basket--all in vain.

Of course, some comrades might say that unless purchase prices for farm products are raised, how is the unreasonably "price scissors" to be reduced or eliminated? We cannot use increases in purchase prices for farm products as the only way in which to eliminate or reduce the "price scissors," much less can we muddle together the two issues of reducing the "price scissors" and increasing peasant income. By "price scissors" is meant the uneven exchange of value of industrial and farm products and its trend of development. It reflects the overly low price paid for farm products, which are sold for less than their value, and the overly high price at which industrial goods are sold, which is more than their value. This sets up an unequal price exchange ratio and exchange relationship between agricultural and industrial products. We do not deny that within price parities in the exchange of industrial and agricultural products in China different degrees of "scissors" do indeed exist; however, this has been formed historically. During the more than 30 years since founding of the People's Republic, in order to reduce the "scissors," both the party and state have gradually increased purchase prices paid for farm products on the one hand, while several times lowering the prices of industrial goods on the other, so that price parities in the exchange of industrial and agricultural goods have gradually moved toward equitability, and the "scissors" has gradually been reduced (For changes in the exchange of major farm products for industrial products, please see the attached table).

From the attached table one can see that the trend in the "scissors" between industrial and agricultural produces has been toward gradual reduction. Most particularly, in 1979 the party and state tremendously increased the purchase prices paid for eight major agricultural and sideline products (the average rate of increase being 22.1 percent with another 7.1 percent hike in 1980). In addition, they instituted increased prices for excess purchases of grain, cotton, and edible oils for fairly substantial increases in peasant incomes. As a result of increased output and raised prices, accumulated increases in peasant income for 1979 and 1980 were 25.8 billion yuan, or an average increase of somewhat more than 30 yuan per peasant. Such a tremendous increase in the purchase prices paid for farm products which had as its objective the increase in peasant earnings and improvement in the livelihood of the 800 million peasants, also substantially reduced the scissors in exchanges of industrial and agricultural products. However, we cannot, for the sake of increasing peasant income, increase purchase prices year after year, much less is it possible to depart from the tasks of developing the national economy and building the national economy in order to increase purchase prices. Increases in purchase prices paid for farm products is not simply a matter of increasing peasant income, nor is it just simply a matter of reducing the "scissors." It can directly influence the prices of industrial goods that use agricultural products as their raw materials, going on to influence the stability of market prices, and to affect development of industrial and agricultural production and improvement in the people's livelihood. Additionally, it can directly bear on the issue of accumulation of capital for the building of the national economy. Therefore, increasing purchase prices requires extreme prudence. The principle of concurrent concern for the interests of the country, the collective, and individuals must be adhered to. There can be no concern for only the interests of a single element.

What is the fundamental way in which to increase peasant income? This means: development of commodity production to realize greater production and unimpeded sales. It is necessary to rely upon correct policies to stir the enthusiasm for socialism of the broad masses of peasants, to actively develop economic diversification even while assuring steady development of grain production, and vigorous improvement in the agricultural labor productivity rate. During the past several years, the state has made needed readjustments in rural production relationships. It has changed the overconcentration in management systems, blind direction in production, egalitarianism in distribution, and such inequitable practices, and it has developed various forms of production responsibility systems. That growth has taken place in agricultural production as a result, and that in many places peasant earnings have increased manifold attests to this. At the same time it is necessary to rely on scientific techniques and scientific management methods for energetic development of natural resources and equitable use of every plot of land including existing cultivated land, mountainlands, hills, grasslands, rivers, lakes, and sea areas, etc. It is necessary to take a new road in agriculture of fairly little investment for relatively high economic benefits. In this way it is possible to form a good link between the readjustment of rural production relationships and development of rural productivity, and to promote the all around development of the agricultural economy, so that the broad masses of peasants can lead a prosperous life.

Table

Per 100 jin of farm products	Industrial goods exchanged	1950	1957	1978	1978 percent of increase over 1950
Wheat	Kerosene (jin)	13	19	38	192.3%
Paddy rice	Sugar (jin)	7	9	14	100.0%
Ginned cotton	White cotton cloth (chi)	286	283	388	35.7%
Fattened hogs	Sugar (jin)	35	48	65	85.7%
Chicken eggs	Kerosene (jin)	39	88	195	400.0%

BRIEFS

NATIONAL LIVE HOG OUTPUT--According to the estimate of the departments concerned, the output of live hogs rose in the first half of 1982. This is an increase of 2.45 million head or 2.7 percent over the same period in 1981. Many provinces and municipalities increased their output by a large margin. Nei Monggol increased by 175.5 percent, Qinghai by 50 percent, Gansu by 28.8 percent, Shanghai Municipality by 20.1 percent, Jilin by 17.8 percent, Jiangsu by 14.5 percent and Anhui by 12.7 percent. The state procured 3 million head, or a 5 percent increase over the same period in 1981. Each live hog gained a net weight of 6.6 jin per head more than in 1981. The number of sows capable of reproduction also increased in the first half of the year by 476,000 head or 2.3 percent over the same period in 1981. [Excerpt] [Beijing RENMIN RIBAO in Chinese 26 Aug 82 p 2]

FARM MACHINE SALES VOLUME--Since February of this year, the situation of China's falling sales volume of farm machine products which has been plaguing China for 3 successive years has begun a turn-around. By the end of June, the national aggregate sales had reached 3 billion yuan, an increase of 8 percent over the same period last year. [Excerpt] [Beijing RENMIN RIBAO in Chinese 28 Aug 82 p 1]

PRC AGRICULTURAL PRODUCTS INCREASE--Since the 3rd plenary session of the 11th Central Committee, China has reaped an all-round harvest in agricultural production. Although, according to the estimates by the State Statistical Bureau, the sown area of grain crops fell somewhat from 1979 to 1981 due to a rational readjustment of overall arrangements in planting, the national grain output has exceeded the pre-1978 level every year since then. For example, the total grain output in 1981 reached 325.02 million tons. Production of various cash crops also increased continuously. The cash crop output in 1981 was: cotton, 59.35 million dan; oil-bearing crops, 204.10 million dan; sugar, 720.57 million dan; and tea, 6.85 million dan. All exceeded the highest level in history, and each increased from 37 percent to 96 percent over 1978. Also in 1981, the gross value of output in forestry, animal husbandry, fishery and sideline production was about 617 millioun yuan (based on 1970 constant price estimates). This figure showed an increase of 31.1 percent over 1978 and an average progressive increase of 9.5 percent per year. [Excerpt] [Beijing RENMIN RIBAO in Chinese 17 Aug 82 p 2]

CSO: 4007/589

AGRICULTURAL TECHNICAL PACKAGE CONTRACT SYSTEM OUTLINED

Guangzhou YANGCHENG WAN BAO in Chinese 14 Jul 82 p 2

[Article by Lu Heyuan [4151 0735 3293]: "Promote Agricultural Techniques Directly Related to Economic Effectiveness--A Talk About Various Forms of Agricultural Technical Contract Systems"]

[Text] Agricultural technique contract systems are a new form of using science and technology to develop agriculture. They employ agricultural technical promotion departments on the one hand, and production units (production teams and peasant households) on the other, the two parties signing agreements on the basis of voluntary participation for mutual benefit. The agricultural technical promotion departments are responsible for setting technical procedures, training peasant technical mainstay cadre, and providing on-site direction, while the production units are responsible for putting technical measures into effect so as to assure application of science and technology, increased agricultural yields, and increased earnings for the peasants. Last year Guangdong Province launched a technical contracts campaign, contracting a crop area of 210,000 mu from which outstanding economic results were obtained from an overwhelming portion. This year the crop area contracted throughout the province already amounts to more than 1 million my, and contracting has been extended from grain crops to economic crops and other economic diversification; not only has there been a comprehensive contracting for increased yields, but also the contracting for individual kinds of techniques, the scope becoming ever greater and the forms increasingly diverse.

Technical contract agreements promoted everywhere in Gunagdong Province have been of the following several kinds:

(1) Agricultural departments (county agricultural bureaus or commune farm techniques stations) and peasants (production teams and peasant households) have a signed comprehensive technical contract agreements. Some of these relate to output, and some do not. Mostly contracting of rice has been done, but there has also been some contracting of sugarcane, peanuts, and such economic crops. In the case of agreements related to output, the principal method used has been the dispatch of technicians by agricultural units in accordance with agreements to help peasants formulate technical procedures, to carry out technical training, to give on-site

direction. In some cases a certain amount of chemical fertilizer, and pesticides have also been provided so the peasants can carry out production in accordance with technical procedures. The two parties negotiate a base figure with any output in excess being proportionally divided. Should reduced yields result from mistaken technical direction, agricultural departments will bear responsibility for paying indemnities. In the case of agreements not linked to output, technical direction fees are collected on the basis of contracted area, any increases in yields reverting entirely to the peasants.

(2) Organization by agricultural departments of peasant technicians to establish technical service teams, with the signing of technical contract agreements with the peasants. The main method used is for natural villages or production teams, acting with the support of commune farm technique stations, to select peasant technical teams from among those who have been trained, who have experience in scientific farming, and who enjoy a certain prestige among the masses to form farm technique service teams, signing technical contract agreements with peasant households (service households), discussing responsibilities both parties are to assume, a technical service fee of 1 to 2 yuan per mu per crop being collected. Agricultural departments periodically provide training to technical service team members to improve their technical levels.

(3) Individual technical contracts signec between plant protection companies and peasants for the prevention and control of crop diseases and insect pests. The company is responsible for disease and insect pest monitoring reports, for technical direction, for providing pesticides (and in some cases the contracting of application of pesticides), paying indemnities for losses beyond those stipulated with the peasants paying a prevention and control fee on the basis of contracted area.

In addition to the aforestated forms, there are contracts linking output, purchases and marketing to new techniques for perennial crops (such as fruits and tea); agreements linking hybrid seed production to yields; and joint operating agreements between agricultural, industrial, and commercial companies and production units.

Last year's experiences show that agricultural techniques contract systems holds the following advantages:

(1) They are beneficial in the implementation of various measures for increasing agricultural output, for accelerating the spread of agricultural science and technology, for improving scientific farming standards, and for increasing economic results. In the past we became accustomed to leaders making a general call, or using administrative command methods, to compel action when we promoted agricultural techniques. Leadership departments took no economic responsibility whatsoever as to whether these techniques were suited to local realities or whether they resulted in increased yields and increased earnings. Consequently, the peasants did not readily accept these new techniques. After employing the technical contracts system, yields increased and excess production was divided up

proportionally between the promoters and the producers. When technical direction was unsuitable and resulted in reduced yields, the promoters had to take responsibility for payment of indemnities. Thus, promotion of agricultural techniques became linked to economic results, with the result that the road to the spread of agricultural techniques came alive. Last year Zhanjiang Prefecture vigorously promoted the growing of hybrid corn as the early crop, but because quite a few places lacked experiences in the farming of hybrid rice, agricultural departments adopted the method of signing technical agreements with peasants to help them master the techniques so that measures for increasing yields were translated into reality. As a result, 290 of the 300 production teams that signed technical agreements with agricultural departments produced increased yields.

(2) Because the agreement methods closely united promotion of technology and production, made the goals synonymous, defined responsibilities, and blended the interests of both parties to the agreements, they helped stir the enthusiasm of all parties for concerted efforts in fulfilling the overfulfilling tasks stipulated in the agreements. Last year the Heyuan County Agricultural Bureau signed a technical agreement with Silaitang Production Team in Dengta Commune for the early crop, the contracted area amounting to 28.9 mu. After the agreement had been signed, the assistant agronomist responsible for providing technical direction, Zhang Yongshu [1729 3057 2873], took various actions to increase yields. As a result, yields averaged 219 jin per mu more than for the same period the previous year, and total output increased 42.8 percent. For the late crop, the scope of contracts was expanded to 191.3 mu of paddyfields in four production teams. Despite serious natural disasters and a general reduction in yields of nearby communes and brigades, the four production teams all realized remarkable increases in yields. One of the production teams had yield increases of 323 jin per mu, and the lowest production team had yield increases of 57 jin per mu.

(3) Raised the technological levels of farm technical cadres and the broad masses of peasants. Following the signing of technical agreements, direction in farm techniques became linked to production results. Farm technical cadres universally felt "pressure," and their zeal for more intense study of technology increased. In addition, training linked to production realities was provided large groups of peasant technical personnel, grassroots cadres, and commune members, and the technical level of the broad masses of peasants was generally raised.

(4) Increased sources of experience for technical promotion work. In the process of promoting the agreements system by agricultural departments, funds derived from the division of production in excess of bare figures could be used to improve work conditions and to increase expenditures for training and for the buying of needed instruments and equipment. They could also be used to give appropriate bonuses to technical cadres concerned for a gradual change in the old notion that "the country spends the money and the peasants farm the fields," as well as in the situation wherein agricultural technical service had been given without compensation. This represented a major change in agricultural technical promotion work.

COTTON PRODUCTION PROSPECTS PROMISING

Shijiazhuang HEBEI RIBAO in Chinese 8 Jul 82 p 1

[Article by Economic Crop Office, Provincial Agriculture Bureau: "Hebei Province Cotton Production Situation Heartening. Area Expanded by Nearly 3 Million My From Last Year With an Increase of 300 to 400 Plants Per Mu. Budding and Blossoming 7 to 10 Days Early"]

[Text] According to reports from everywhere and onsite observations of units concerned, cotton growth throughout the province is very heartening.

The fine situation this year in cotton production throughout the province is manifested in three ways as follows: First, the cottonfield area is large and cotton in plentiful. Thanks to the arduous efforts of cotton growing peasants in combating drought this year, 10.71 million mu of cotton was planted, which was 3 million mu more than last year. This is the first time since 1966 that the 10 million mu mark has been broken. This a general reflection of the grading of former cottonfield plants, which was in the shape of a mountain with little good cotton and much second rate cotton. This year's grades of cottonfields is like an inverted pagoda, with much good cotton and little inferior cotton for an even growth situation. A survey done at the end of June shows 4.4 million my of first grade cottonfields amounting to 41 percent of the total cottonfield area, a 10 percent increase over the same period last year. This has been rare for many years. Second is the full stand of plants of sensible density, vigorous growth, and numerous fruiting branches. Full stand and substantially full stand cottonfield cover 9.4 million my, or 88 percent of the total area, an 8 percent increase over last year. Furthermore, the number of plants retained have had fairly numerous and of sensible density, with the number of plants retained being about 4,400 per mu. Right now the cotton has reached a height of more than 1 chi, and good cotton plants have seven or eight fruiting branches; run-of-the-mill plants have five or six fruiting branches. Plants are from 1 to 2 cun taller than last year and fruiting branches more numerous by three or four. Moreover, cotton plants are sturdy, stems are thick, and nodes are c-ose together. Leaf color is deep green. Third, budding and blossoming has been 7 to 10 days earlier than last year, and buds are both large and numerous. Budding has already taken place on more than 8.8 million mu, or 83 percent of the total area. Individual plants have formed 8 to 9 buds, the budding area increasing by 23 percent over last year. Individual plants have formed between two and three more buds.

Right now the cotton fields are growing well, and the enthusiasm of cotton growing peasants is greater. The broad masses of cotton growing peasants are now taking a firm grip on cottonfield care, determined to conquer all kinds of disasters and win a bumper cotton harvest this year.

BRIEFS

EARLY RICE HARVEST--Hunan Province reaped a bumper harvest of early rice this year with an estimated total output nearing 20 billion jin, an increase of more than 300 million jin over the bumper year of 1981. Both its per unit yield and total output exceeded the highest level in history. Of the 16 prefectures and municipalities in the entire province, 9 have increased output. Of these, Changde and Yiyang prefectures increased their output by more than 100 million jin over 1981, and Yueyang Prefecture and Changsha Municipality increased output by 96 million jin and 40 million jin respectively. XUZHOU PREFECTURE WHEAT OUTPUT INCREASED DESPITE DROUGHT

Nanjing XINHUA RIBAO in Chinese 26 Jun 82 p 1

[Article: "Xuzhou Prefecture Total Wheat Output 300 Million Jin More Than in 1981; Triumph Over Protracted Drought To Win Bumper Harvest From Summer Crop"]

[Text] Xuzhou Prefecture cadres and commune members have triumphed over calamities, including drought, high temperatures, and overcast, rainy weather, to achieve a bumper harvest from the summer crop. Output from over 6 million mu of wheat totals over 2.7 billion jin, an increase of more than 300 million jin over 1981. Every one of the eight counties in the prefecture had increased yields. In Pi, Suining, Donghai, and Feng Counties, the total output surpassed all-time highs. Rape output for the prefecture amounted to more than 90 million jin, more than twice as much as in 1981.

One of the main reasons for Xuzhou Prefecture's bumper harvest this summer was the tremendous stimulation of the masses of commune members throughout the prefecture to combat drought and achieve a bumper harvesting resulting from the agricultural production responsibility system. During the entire period of growth of summer ripening crops in Xuzhou Prefecture, winter drought was followed by spring drought, which was followed by summer drought. For a period of 7 months, the amount of rainfall was only one-third normal. Since the beginning of April, in particular, the drought situation has worsened. The drought-stricken wheat growing area in the prefecture amounts to more than 2 million mu. In order to achieve a bumper harvest from this year's summer crop, the broad masses of cadres and commune members throughout the prefecture firmly established an attitude of protracted combat against drought. During last autumn's sowing season, they created soil mosture, and rushed to take advantage of soil moisture for early sowing at the right time in order to get a full stand of crops. During the winter, they fought drought by watering more than 3.7 million mu of wheat. Following the lunar new year, in addition to providing a top dressing of fertilizer, they watered more than 2 million mu of wheat. The drought continued to develop beyond the end of May, and the prefecture CCP committee and government administrative offices held an emergency meeting on fighting drought in Feng County, where the drought was most severe. The conference promoted the experiences of Wanggou Commune in Feng County in carrying forward a spirit of self-reliance and arduous struggle to combat drought and protect the wheat. Throughout the prefecture a surge began, with men, women, old and young all pitching in, every available means being used to combat drought and achieve a bumper harvest. At the crucial time in the combat against drought to save the wheat, the prefecture daily fielded more than 1 million people to combat the drought by watering a total of over 2 million mu of wheat. Cadres and commune members said that such a good wheat harvest this year is the result of arousing the enthusiasm of all concerned by party policies and their efforts in watering the crops.

METHODS OF IMPROVING PORK SALES DISCUSSED

Call for More Lean Pork

Nanjing XINHUA RIBAO in Chinese 28 Jun 82 p 1

[Article by Qian Feng [6929 6912]]

[Text] China raises more hogs than any other country in the world, and pork is the main meat the Chinese people eat. It can also be exported for foreign exchange to support building the four modernizations. Since the smashing of the "gang of four," party policies have stirred the enthusiasm of the peasants for hog raising, and this plus the fine grain harvests has brought rapid development of hog raising enterprises. In 1978, the state purchase of live hogs in Jiangsu Province totaled 10.69 million head. In 1981, the number was 16.31 million head, and for the first quarter of 1982 the number purchased was 4 million. In both city and countryside pork supplies are freely available, and annually hundreds of thousands of tons of pork are supplied for export, which is certainly a heartening matter.

However, during the past 2 years a problem of hogs tending to be overly fat has gradually cropped up. In 1981, the live hogs that were purchased averaged more than 181 jin in weight, over 14 jin more than in 1980. In northern Jiangsu prefectures that grow grains other than wheat and rice, the average weight was more than 230 jin. In the Lake Tai rice-growing region, where live hogs have historically been removed from inventory upon reaching a weight of about 110 jin, they weighed an average of more than 150 jin. Though the period January to April this year has been a slack season for the arrival of hogs to market, the average weight per head for hogs purchased in the province has been more than 185 jin, an increase of more than 21 jin over the same period last year. The hogs tend to be larger and their meat is also overly fat. A survey carried out in Nanjing Municipality shows that among live hogs slaughtered in 1975, for every 100 jin of pork, about 35 jin of lean pork could be cut. This year, however, the amount is only about 19 jin. On the other hand, the number of consumers hoping to buy lean pork have risen to more than 70 percent. In medium-size and small cities and market towns, and even in some rural villages, the demand for supplies of lean pork have steadily increased. Customers want to cast aside fat pork and choose the lean, and business people want to throw in more fat when they sell the lean, which often causes tempers to flare. This conflict between sellers and buyers reflects, in essence, the conflict between supply and demand. As a result of year after year of bumper rape harvests, supplies of rapeseed oil have increased and prices have fallen, so the market for lard has also become an increasingly small one. Reportedly the problem of overly fat live hogs exists in other hog-producing provinces too. Today the level of pork consumption by the people of the country is by no means high; however, overly fat hogs have hurt pork sales. Recently we strolled through Nanjing markets, where the sights we saw aroused concern. Many customers "looked at the pork and sighed with delight," while many sellers "looked at the pork and worried." How can this situation be changed? The key lies in clear improvement in economic benefits as the guiding mentality in hog raising, meaning that hogs with a lot of lean pork that meet the requirements of society have to be produced. The production requirements should specify not only great quantity, but also high quality. In this regard, we put forward the following suggestions for the reference of those concerned when studying the problem.

1. Hasten the transitional process from fatty meat hog varieties to lean meat varieties. This work must move quickly from the stage of academic study to the practical stage. China's pork resources are abundant, and the country's financial situation does not permit large imports of lean meat hog varieties. Experiments conducted in this province show that the increase of the lean meat rate requires, as a first step, the crossing of lean meat type boars with the province's fine variety local sows, and carrying out binary or tertiary crosses. It is also necessary, at the same time, to improve feeding techniques. Efforts should be made to obtain, within a period of about 5 years, a 10-percent or more increase in the lean meat rate.

2. As a matter of state procurement policy, the principle of superior price for superior quality should be followed to encourage the growing of hogs with a high rate of lean meat, and to curb the raising of overly fat hogs, guiding hog raising households to produce pork that meets the needs of society.

3. Pork should be supplied in cuts. While maintaining the existing centralized pork price levels, the difference in price between lean and fat pork should be suitably increased and different prices set for different pork cuts so that lean pork, porkchops, and such meats that are in great demand will be displayed in the markets, and so that fat pork can be sold, too, to meet the needs of different consumers.

This method will aid the continued development of the province's live hog production, improve the level of hog raising, help satisfy consumers, cause the markets to flourish, provide real benefits for producers and consumers alike, and offer hope for a reasonably good solution to the conflict between customers and sellers.

Different Cuts of Pork

Nanjing XINHUA RIBAO in Chinese 7 Jul 82 p 2

[Text] Beginning today, throughout the urban area of Nanjing all-round promotion will be given to the supply of different cuts of pork. This decision was reached yesterday by the municipal government.

All year long pork supplies have been fairly large in Nanjing markets. The meat has also been too fat, and fat pork has been sold as lean pork, which has caused a tense situation between sellers and their customers. In order to alleviate the conflict between supply and demand, on 27 May Nanjing began to run pilot projects on price differences for fat and lean pork and for the supply of different cuts of meat in 19 urban food markets. After more than a month, the overall situation in these pilot projects is good.

Simultaneous with the all-round promotion of supplies of various cuts of pork has been the institution of new prices for cuts. The trial prices have been cancelled, but uniform wholesale and retail prices for pork have not been changed. Under the new system of supplying cuts, prices for pork ribs, neck portions, and pork bellies have been adjusted downward, while prices for lean meat and chops have been adjusted upward, to meet the needs of different consumers. In addition, all food markets continue to maintain supply counters where the masses can select purchases.

IDEAS ABOUT SURPLUS WORKFORCE PROBLEM SKETCHED

Beijing ZHONGGUO NONGMIN BAO in Chinese 15 Jul 82 pp 1, 2

[Article by Nei Monggol CCP Committee First Secretary Zhou Hui [0719 1920]: "Actively Guide Rural Surplus Workforces To Devote Efforts to 'The Land'"]

[Text] How to solve the problem of surplus rural workforces is something that has emerged in some places for the past 2 years. Following visits to rural villages during June and July, I feel that this problem is fairly widespread. This results primarily from the current practice of various forms of responsibility systems whereby output quotas are fixed for households or whereby households assume full responsibility for task completion about which the broad masses of peasants are fairly satisfied; consequently enthusiasm for labor and production is very high and the labor productivity rate is very much higher than formerly. Thus, apart from those needed to farm existing land and engage in household sideline production, a general one-third or so of the workforce is surplus. This has become a major problem in rural villages today requiring urgent solution.

The appearance of surplus rural workforces results from the various economic policies followed in rural villages since the Third Plenary Session of the 11th Party Central Committee. It also provides a major potential for our further enlivening of the rural economy, for improving reproduction capabilities, for developing the collective and individual commune member commodity economy, and for guiding the peasants to become prosperous with all possible speed. We must adroitly guide actions according to circumstances and strive to make peasant enthusiasm for production endure for a long time, and to steadily lead them to in-breadth and in-depth progress in production. This problem will become a major ingredient in the perfection of rural production responsibility systems requiring all jurisdictions to proceed from realities and to adapt general methods to local situations in diligent solution.

How can one go about solving the surplus rural workforce problem? Generally speaking the following ways are open. Some places have developed commune and brigade enterprises; some have contracted to do hauling or to work on city construction projects; some have gone to cities to run service trades such as restaurants; and some have developed dairy cattle, sheep and goat, hog, chicken and bee raising industries, etc. All such things may continue to develop in accordance with realities in individual areas. However, on the basis of overall circumstances within the Nei Monggol Autonomous Region, for the present and for some time in the future, the main efforts will have to be devoted to "the land" first of all, meaning it will be necessary to organize surplus workforces for intensive farming of existing cultivated land for steady increase in yields per unit of area and output value, growing trees and grass on barren sandy wastes, barren mountains and idle wastelands. In so doing, not only is there no conflict with the foregoing ways, but rather they can be mutually promoting, making every production avenue truly increasingly broad. For example, in regard to the problem of placing efforts on existing cultivated land, the region currently has somewhat more than 80 million mu of cultivated land from which actual yields are less than 200 jin per mu, the yields from oil-bearing crops and sugarbeets are not very high either. The situation is one of continuing widespread planting for meager harvests. Were we to guide the peasants in intensive farming and steadily increase the level of scientific farming, while at the same time gradually adapting general methods to local situations to do some farmland capital construction, both yields per unit of area and output value would increase year by year. A look at the most recently investigated situations shows the potential in this regard to be very great. We visited two commune member households in Xiatanvv Production Brigade, Zhongtan Commune, Toketo County. Last year they handed over to the state between 3,000 and 4,000 jin of grain and they still have grain reserves enough for more than half a year. Earnings per household averaged more than 500 yuan, and one household had earnings of more than 800 yuan. This brigade had once been a notorious "three dependencies brigade," which has changed this greatly within 3 years following institution of responsibility systems.

Another example is in the use of barren sandy wastes, barren mountains, and idle wastelands, with major efforts to plant trees and grass. The total area of the Nei Monggol Autonomous Region is 1.8 billion mu. In addition to cultivated land and fairly good pasturelands, it also contains a large amount of sandy wastes, barren mountains, and idle wastelands, most of which could be used to grow trees and grass. In early May I made an inspection of Beishuiquan Commune in Liangcheng County, Wulanchabu League where I particularly went to see the woodlands of their specialized forestry team. Formerly this was an area of bald mountains and barren ranges. Subsequently it was planted to pine trees, suanci [6808 0459], grass, bushes and shrubs, and within only 3 years time the mountain is entirely green. In this way not only was the ground cover gradually restored and a new natural ecological balance established to create fine conditions for the farming industry, but the natural strengths of the entire region could be fully used, and the potential of natural resources could be fully tapped to lay a foundation for development of a breeding industry, a gathering industry, a plaiting industry, a processing industry for farm, forestry, and livestock products, and other economic diversification. The pace of modernization accelerated.

In order to lead the post-production responsibility system surplus workforces into intensive farming of available cultivated land, togrow trees and grass on barren sandy wastes, barren mountains, and idle wastelands, and to be genuinely effective, a series of policy measures is needed to provide assurance. I feel that most important is solution to three problems as follows: One is to get understanding of the problem, namely by publicizing representative surveys and the natural character of Nei Monggol to get people to understand in terms of present and longterm interests the importance of devoting efforts primarily to "the land." Second is the benefits problem, by which is meant finding means whereby the peasants not only realize the longterm benefits, but also are able to obtain real benefits right now. Third is scientific and technological problems. Right now scientific levels in farming, growing of trees and grass is fairly low, and has to be raised correspondingly and with all possible speed. This requires, in turn, the formulation of policies and regulations. For example, planned and speedy allocation to peasants and herdsmen of barren wastelands, barren mountains, idle wastelands, and water surfaces with suitable conditions, collective and state organizations growing trees and grass in development of economic diversification. The government should issue certificates of ownership to commune members and collectives (specialized contracting to households or individual workers may be done) who grow the trees and grass, with it being made clear that commune members are to have inheritance rights for the trees and grass they grow. All levels of government also have to encourage and support collective organization of specialized crops to deal with the "three wastes." Places lacking conditions for the growing of grain crops may adopt the method of large-scale assignment of responsibilities, the state providing grain and the commune members concentrating their efforts on the growing of grass and trees in the development of economic diversification. Seedlings and grass seed required by commune members for the growing of trees and grass should be provided gratis, or at low prices, by the state or collective. In order that thepeasants and herdsmen will receive benefits within a short period of time, so long as normal growth of tree seedlings is maintained, they should be permitted to intercrop trees with oil-bearing crops, medicinal herbs, grass, or other economic crops. Shrubs and bushes may be combined with grass, and the long-term and the short-term combined, the short-term used to nurture the long-term. A mobilization of forces from every quarter is required, and all trades and industries engaged in science and technology, industry, communications, finance, and trade, or public finance and banking will have to help peasants broaden production avenues.

Throughout the region a group of representative examples of prosperity through labor have emerged primarily in the farming and breeding industries, and in economic diversification into forestry, animal husbandry, and fishing as an adjunct to agriculture. These representative examples have very great attraction for the broad masses of surplus rural labor, and all jurisdictions should widely publicize them. Representative examples are most convincing. When they have the experience of representative examples the peasants can follow to do the same thing. Of course, in some places mentalities have yet to be emancipated, and households that act in accordance with party policies, make the most of their own workforces and skills, and become prosperous through arduous labor are not supported with boldness and assurance, but rather have all manner of reproach raised against them, or are subjected to freezing irony and burning satire so that some households that have become prosperous through labor are afraid and apprehensive. This directly contravenes the spirit of the Third Plenary

Session, and is extremely unfavorable for the opening of broad avenues of production and providing for surplus rural workforces. We must continue to clean out the influence of "leftist" ideology and further propagandize and carry into effect the party's line, programs, and policies. We must indoctrinate cadres at all levels so that they will understand how to use local natural resources to become prosperous through labor. Our duty is not to restrict but rather to lead enthusiastically, to encourage and support, and, to the maximum degree possible, to lead surplus peasant and herdsmen workforces to advance in production in depth and breadth.

AUTONOMOUS REGION CHAIRMAN OUTLINES ORIENTATION OF AGRICULTURE

Yinchuan NINGXIA RIBAO in Chinese 29 Jun 82 p 1

[Article: "Reliance on Policies and Science To Win Sustained Increase in Agricultural Production This Year, Chairman Ma Xin [7456 0207] Points Out in Government Work Report as Being the Major Task in the Region's Economic Work This Year"]

[Text] Reliance on policies and science to win sustained development of agricultural production is the major task noted in Chairman Ma Xin's government work report in the region's economic work this year. He said that the gross output value from agriculture assigned the Ningxia-Hui Autonomous Region in the 1982 state plan is 766 million yuan, and a grain output totaling 2.44 billion jin. Though there is a certain amount of leeway in this as compared with actual output during 1981, because of the fairly frequent natural disasters during the first half of this year, we positively cannot lower our guard.

In his report, Chairman Ma Xin pointed out that the key to winning sustained increases in agriculture this year still lies in reliance on policies and on science. There is need to continue to carry out the various policies that have followed from the Third Plenary Session [of the 11th Party Central Committee], to adhere to the collectivized path of socialism, to maintain public ownership of the means of production unchanged for a long period of time, and production responsibility systems unchanged for a long period of time. Responsibility systems have to be assiduously summarized, perfected, and consolidated. For the various forms of responsibility systems that have already been established, so long as they help development of production, help consolidate the collective economy, and are supported by most of the masses, there is no need to change them. A good job has to be done with commune and brigade leadership teams, a commune and brigade cadre presonal responsibility system has to be established, the responsibilities of one's own position defined, and the state of paralysis or semi-paralysis of some leadership teams genuinely resolved. It is necessary to proceed from realities in diligently studying and solving various new circumstances and new problems that have arisen in the institution of responsibility systems. No matter the form of responsibility system practiced, production planning must be subordinate to unified state planning. The peasants should be regularly indoctrinated in love for country, love for the collective, concurrent concern for the interests of the three[the country, the collective, and individuals], in acceptance of plan direction, and in striving to support the building of socialism.

The report said that in accordance with the program of "positively no relaxation in grain production while actively developing economic diversification" in combination with the realities and different characteristics of the region, the Huang He irrigation area is to be built gradually into an economic zone predominantely devoted to commodity grain, but with integrated development of agriculture, industry, and commerce. The southern mountain area is to be built gradually into an economic zone in which forestry, livestock products, and commodity oils predominate for a combination of farming and forestry with self-sufficiency in grain. Most important in doing a good job of grain production is scientific farming and intensive farming to increase yields per unit of area. While assuring increased grain production for the region as a whole, equal emphasis has to go to the collective and individuals in an adaptation of general methods to local situations for development of economic diversification, to broaden production avenues, and to go forward in agricultural production in depth and in breadth.

In this report, Chairman Ma Xin called upon all levels of government and the Afforestation Committee to make the campaign for the planting of trees for afforestation and the greening of the mountains and the valleys routine and sustained, and taking a firm grip on its implementation. The focal point of tree planting for afforestation in the region is on doing a good job of creating a woodland network in irrigation area farmlands and along roads, and the "growing of trees, grass, and shrubs" in mountain areas, with earnest efforts being devoted to the project for buildng shelter forests in Xiji County. Afforestation should be done scientifically; quality of afforestation should be improved; and care and protection should be intensified.

The report said that simultaneous with major efforts to develop both collective and individual commune member raising of hogs, sheep and goats, there should be an adaptation of general methods to local situations for development of dairy cattle, dairy goats, beekeeping, and rabbit raising. Attention should be given development of aquatic products production. It is necessary to proceed from realities in the development of the region's farming, forestry, animal husbandry, sideline occupations, and fishing industry, and to further buttress scientific agricultural research and the promotion of technology. The building of the four base counties of Guyuan, Yanchi, Xiji, and Pingluo should be diligently summarized and improved to make fullest use of the role of these base counties in the modernization of agriculture.

PLANNED ASPECTS OF FARM PRODUCTION EMPHASIZED

Yinchuan NINGXIZ RIBAO in Chinese 1 Jul 82 p 2

[Article by Guo Shizhong [6753 0013 1813]: "Bolstering Planned Management of the Agricultural Economy"]

[Text] Ever since institution in the farflung rural villages of the region of production responsibility systems predominantly in the form of peasant households assuming full responsibility for task completion, the fruits of commune member labor and economic benefits have been fairly closely linked; the enthusiasm for work of the peasant masses has been high, and the sense of responsibility for production strong, all of which have played an active role in promoting the development of agricultural production. However, some cadres and members of the masses also wrongly suppose that now that assumption of full responsibility for task completion by peasant households has been instituted, one can farm any way he pleases. As a result, when making plans for production, some production teams and commune members give no thought to the country's needs and ignore plan guidance fromsuperior authority. When it is very clear that not so much of certain things is needed, they blindly expand its production for the sake of large profits, creating overstocking. Because profits to be made are small, some things needed by society are not actively produced, with the result that procurement plans are not fulfilled. Among some of the production teams and commune members in the close-in suburbs of Yinchuan who grow mostly vegetables, a mentality of slighting the growing of vegetables exists, and during the season when vegetables are planted and taken care of, large numbers of the workforce are transferred elsewhere to engage in sideline occupations to the detriment of begetable production. Among some of the production teams that institute the centralized growing of vegetables with grain production being assigned peasant households for full assumption of responsib-lity for completion, there is also a tendency to emphasize the growing of grain and to slight the growing of vegetables, which impairs fulfillment of vegetable procurement plans. In sales to the state of agricultural by-products, some commune members that have not fulfilled their state grain sales quotas sell large quantities of commodities in country fair markets.

In view of the new circumstances in rural villages today, how can plan guidance of agriculture be strengthened and planned management of the agricultural economy be perfected. First of all it is necessary to take in hand political and ideological work, conducting education of the peasants in socialism, patriotism, and collectivism for a correct understanding and handling of the relationships among the welfare of the state, the collective, and individuals. Concepts of the overall situation must be established, and there can positively be no concern only for one's own welfare while not caring for the welfare of the state and the collective. The peasants must be made to understand that only by opening production avenues under guidance of state plans, through arduous labor, and by producing more of the goods that society needs can incomes steadily increase so that they themselves can become prosperous.

Secondly, all levels of planning departments and other pertinent units should intensify investigation and study, and make planning more scientific. In formulating plans, it is necessary to dig into realities and do a good job of investigation and study. It is necessary both to consider the needs of the country and to examine real possibilities. It is necessary to adapt general methods to local situations, to make use of strengths, to be active and reliable, and to leave some room for maneuver.

Third is the need to gradually establish and perfect the economic agreements system. Throughout the farflung rural villages, various forms of an economic agreements system are being promoted today. This is a major action for implementing state plans under the new circumstances. Already established economic agreements systems require further improvement. Not only should there be production agreements, but sales agreements as well, production agreements and procurement agreements being linked so that state procurement plans can be translated into reality. Agreements should be signed promptly each year, preferably in advance of spring sowing, to allow peasants to plan production early. Those who violate agreements are to be economically penalized to maintain the solemnity of agreements. For goods not included in procurement or assigned procurement quotas, departments concerned are to provide the peasants with timely information on the market as a guide for production. All planning departments are to actively coordinate solution to conflicts between agriculture and commerce, strengthening the planning function and overcoming blindness. Only in this way will it be possible to carry into effect a program of "taking the planned economy as the key link with market regulation being supplementary" to promote the building of the four modernizations and to improve the people's standard of living.

PROVINCIAL NOTICE ISSUED ON SUMMER FARM WORK

Yinchuan NINGXIA RIBAO in Chinese 20 Jun 82 p 1

[Article: "Ningxia-Hui Autonomous Region People's Government Notice On Mobilization to Carry Out the 'Three Summer Jobs' in a Solid Way. (28 June 1982, Not Otherwise Circulated)"]

[Text] The "three summer jobs" [harvesting, planting, and field care] season will soon be here. No opportunity should be missed to do a good job of the summer harvest in order to achieve increased summer grain yields, to plant autumn grain well and in sufficient amount, and to intensify care of autumn grain and economic crop fields. This holds major significance for achieving a bumper harvest for the years as a whole. In order to concentrate energies to achieve victory in the "three summer jobs," the following notice has been specially prepared.

1. Conscientious implementation of the spirit of the regional agricultural work conference to increase ideological understanding. The regional agricultural work conference recently convened by the autonomous region people's government relayed the important directive from the CCP committee leadership comrades on work in Ningxia, summarized and analyzed this year's agricultural production situation, studied the problems existing in the agricultural production, and proposed major methods of working unrelentingly for 4 months to achieve an all-round bumper farm harvest this year. All jurisdictions are to conscientiously transmit the directive for implementation and insure that it is carried out. Cadres and the masses are to be educated in a correct understanding of the present agricultural production situation so that they are aware of both favorable conditions and unfavorable factors and existing problems, and resolutely overcome both feelings of blind optimism and pessimistic loss of hope. There is to be continued pervasive propagation of the principle of "one adherence," "two no changes," and "three concurrent concerns" to arouse collective and individual enthusiasm, with everything that should be centralized being centralized, and everything that should be contracted out being contracted out, in a combination of centralization and contracting; adaptation of general methods to specific situations for the perfection of agricultural production responsibility systems; and effective organization of harvesting, planting, and field care during the period of the "three summer jobs," in order to fully arouse all forces to commit themselves to the "three summer jobs" battle.

2. Firm establishment of an attitude of combating disasters to achieve a bumper harvest for timely completion of the "three summer jobs." Meteorological forecasts call for a fairly large amount of rain during July and August this year. Low temperatures with cold damage and other natural disasters may also occur. Leaders at all levels as well as the broad masses of people must firmly establish an attitude of combating disasters to achieve a bumper harvest, guarding against disasters ahead of time, combating disasters when they exist, and preparing early in order to provide against possible trouble.

The summer harvest is a struggle to snatch food from the dragon's mouth requiring good organization of the workforce and draft animals, and the operation of all harvesting, hauling, and threshing machines, putting them to work on the summer harvest at the right time. In the case of brigades in which peasant households are assuming full responsibility for task completion, in particular, machinery should be assembled on the basis of voluntary participation for mutual benefit to carry out harvesting and threshing for commune members, with commune members paying equitable compensation. Regarding hardship households lacking a workforce, the fine tradition of solidarity and mutual assistance is to be maintained, with relatives helping relatives, neighbors helping neighbors, and active help being given to the dependents of martyrs and military servicemen in harvesting the summer crop. Wheat is to be harvested promptly when it is in the waxy stage of ripeness; harvesting, hauling and milling are all to be carried out on time; both harvesting and threshing are to be accomplished painstakingly, and the grain is to be stored in granaries. In addition, grain from selected fields and selected heads is to be kept as seed grain.

Multiple cropping and sowing of the late fall crop is to be carried out promptly in a combination of soil use and soil nurture. In southern parts of the province, multiple cropping should be accomplished in accordance with state plans, with adaptation of general methods to local situations, and the growing of minor oil-bearing crops is to be encouraged. In northern parts of the province, the emphasis should be on various kinds of green manure. Mountain areas should emphasize buckwheat, quick growing broomcorn millet, and similar late autumn crops that can be rush planted to take advantage of soil moisture. Disaster-stricken communes and brigades, in particular, are to plant autumn vegetables and fodder grass to the fullest extent possible, using the autumn to make up for summer shortfalls.

While taking a firm grip on summer harvesting and planting, very serious attention should be given to field care of the autumn grain. In the Huang He diversion irrigation area, there should be application of a top dressing of fertilizer to paddy rice at the right time and in the right amount, weeding, and the raising and lowering of water in the paddy fields should be managed so that the paddy rice will reach full heading safely. Attention should be given to weeding and to prevention and control of diseases and insect pests in sugarbeets in an effort to get a bumper sugar harvest. In mountain regions, the tasks of loosening the soil, weeding, conserving water, maintaining soil moisture, and guarding against and dispelling hailstones in grain growing areas should be taken firmly in hand in an effort to increase yields and earnings.

3. Intensification of safety education to do a good job of keeping the summer harvest safe. Before the summer harvest begins, various methods should be used to educate the masses in the legal system and in fire prevention, robbery prevention, and accident prevention, to formulate "village rules and civilian pacts," and to establish and perfect security preservation organizations and personnel security personal responsibility systems. Work sites and storage buildings are to be made secure and all hidden dangers that might cause accidents removed to insure summer harvest safety. Vigilance should be heightened to strictly prevent and strike down the destructive activities of lawless elements.

4. Education in the "three concurrent concerns." The masses are to be widely and pervasively educated in love of country and love of socialism, as well as in concurrent concern for the welfare of the country, the collective and the individual, active fulfillment of state procurement quotas, full payment of collective withholdings in accordance with agreements, and providing grain rations to the households enjoying the five guarantees [childless and infirm elderly persons who are guaranteed food, clothing, medical care, housing and burial expenses by the people's commune] and to the dependents of martyrs and servicemen. Communes, brigades, and peasant households with increased yields are to sell surplus grain to make a greater contribution and support national construction. Erroneous tendencies toward concern only for the individual and no active fulfillment of state purchase quotas or collective withholding is to be guarded against. Communes and brigades that practice unified production team accounting and unified distribution are to verify summer grain output and economic revenues and expenditures and do a good job of advance summer distribution. Communes and brigades practicing household assumption of full responsibility for task completion are to see to it that contract agreements are strictly honored, that all withholdings have been made in accordance with agreements, and that the solemnity of agreements is upheld. Experiences are to be constantly summarized, contract agreements perfected, and the responsibilities, rights, and benefits of peasant households dovetailed with state plans and the collective welfare.

5. Strengthening of leadership over the "three summer jobs." All government administrative offices, municipalities, and counties are to set up command organizations for the "three summer jobs," and organize skilled and quick-witted personnel to be in charge of matters for prompt, correct, and all-around understanding of situations, the summarization and exchange of experiences, and to give highly effective direction. All levels of leaders are to lead cadres into the frontlines of the "three summer jobs" to survey the situation, summarize new experiences, and solve real problems in the "three summer jobs." Business, supply and marketing, fiscal, and banking departments are to address themselves to new circumstances in order to provide increased services, improve their service attitudes, and assure that a good job is done in supplying chemical fertilizer, pesticide machines, small farm implements, and gasoline and diesel fuel for agricultural use. Grain units are to follow the principle of accommodating the masses in grasping summer grain procurement for the state, and procurement for the state at negotiated prices. They are also to provide seeds promptly for multiple cropping. Water conservancy departments are to strengthen management

of irrigation to insure water for use on paddy rice and other autumn grains. Electrical industry departments are to vigorously propagandize general knowledge about the safe use of electricity, inspect electric power lines, and insure the regular supply and safe use of electricity. All trades and industries in all sectors are to coordinate closely and strive jointly to assure no lost opportunities in completion of the "three summer jobs."

WARNING ISSUED AGAINST OVERPLANTING OF TOBACCO

Xian SHAANXI RIBAO in Chinese 28 Feb 82 p 2

[Article by Wang Hanzhi [3769 3352 2535] and Wen Meihui [3080 2734 1920]: "Flue-cured Tobacco Should Be Grown According to Plan"]

[Text] During the past 2 years, fairly great development has taken place in the production of flue-cured tobacco in Shaanxi Province. In 1981 output of flue-cured tobacco totaled 270,000 dan, and state procurement was almost 270,000 dan. In both production and procurement, plan quotas were fulfilled for a rapid turn around in the situation of tobacco leaf supply not meeting demand.

On the basis of the province's cigarette production quota and the market situation for this year, plus consideration to the trend of development of cigarette production next year, total planned tobacco output for 1982 is 400,000 dan, up 48.2 percent from last year, quite a rate of speed. However, it has been recently reported that communes and brigades in some prefectures are thinking of breaking through the plan quotas handed down by the province. Unless this is corrected, this year's growing area may top 250,000 mu for a total output that breaks the 500,000 dan mark.

The agricultural economy is an important integral part of the whole national economy, and the agricultural economy also has to follow the flexible principle of taking the planned economy as the key link, market regulation being supplementary, and market regulation being only under guidance of state plan. To be concerned only for momentary benefits with no concern for national needs, growing whatever happens to be profitable and attacking state plan can lead to many future contradictions. In 1978, Shaanxi Province singlemindedly pursued quantity as a result of ignoring the adaptation of general methods to local situations in making plans. Though total output reached 275,000 dan, quality was inferior causing slack sales and incurring losses for both the country and the collective, and leading to a tremendous decline in flue-cured tobacco in 1979, total output falling to 97,000 dan. The conflict between production and needs was extremely prominent. We cannot forget this lesson, and we positively cannot cast state plans aside just because some production team "got rich off of tobacco" last year, proceeding only from personal interests to blind expansions of the flue-cured tobacco growing area.

Tobacco production must be commensurate with cigarette production capabilities and quantities that can be sold in the market. Shaanxi Province's cigarette production quota for this year is between 300,000 and 330,000 cases. Blending requires bringing some tobacco into the province from outside, so only between 250,000 and 300,000 dan of tobacco from this province is needed. Plans call for a total tobacco output this year of 400,000 dan, meaning a surplus of about 100,000 dan. This has already taken into consideration an expansion of cigarette production capacity next year. It is anticipated that no great increase will take place within a short period of time in the amount of market sales of tobacco. Looked at in terms of markets in the country as a whole, there are indications that a surplus of tobacco already exists. Furthermore, the province's tobacco farming techniques, flue curing capabilities, and storage facilities cannot cope. Blind expansion of tobacco growing is dangerous. Only by growing according to state plan will it be possible to concurrently consider the interests of the country, the collective and individual commune members. On this point there can be absolutely no carelessness.

USE OF POLYVINYL CHLORIDE PLASTIC FILM FOR GROWING SEEDLINGS URGED

Xian SHAANXI RIBAO in Chinese 28 Feb 82 p 2

[Article by Wang Guanli [3769 0385 0448]: "Proposed Promotion of Use of Polyvinyl Chloride Plastic Film to Raise Seedlings"]

[Text] Ever since last fall a shortage of the plastic film needed to raise seedlings has occurred in Shaanxi Province. How can this problem be solved? One way is to economize on its use and to take care of the plastic that communes and brigades presently have for the raising of seedlings to extend the time it can be used. The second is to promote vigorously throughout the rural villages of the province the use of polyvinyl chloride plastic film as a film for raising seedlings.

Use of plastic film to raise seedlings is an important technique in scientific farming. In the early 1960's when China began to use plastic film to raise seedlings, the film it used was polyvinyl chloride, which is made by using polyvinyl chloride resin as a raw material to which diverse chemical boosters are added, which is then blown. It is highly pliable, tough, and stetchable, light permeable, and has a long useful life. Furthermore, the polyvinyl chloride resin raw material is limestone, which is abundant, readily obtainable, and has substantial developmental prospects. Economic benefits derived from the growing of seedlings are also extremely outstanding.

Formerly, however, when some places used polyvinyl chloride plastic film to raise seedlings, there were instances in which the seedlings either died or suffered damage. Investigation and study showed that the cause of this problem was that when some production plants produced polyvinyl chloride plastic film for raising seedlings in 1975, they mixed in a plasticizer imported from abroad, dibutyl phthlate. This plasticizer is toxic to some farm crops. Thereafter it was not further produced in China. Scientific evaluation shows polyvinyl chloride film to be non-toxic to plants, and in most parts of China today this plastic film is used to raise seedlings. But ever since that accidental destruction of seedlings, Shaanxi Province has changed to the use of polyethylene plastic film for the raising of seedlings. Even though thir plastic film has certain advantages, as compared with polyvinyl chloride plastic film, its light permeability is poor, its strength is low, and it cracks easily. Furthermore, the raw material used to make polyethylene is a byproduct of the cracking of petroleum, which becomes increasingly scarce as the shortage of petroleum increases. Shaanxi Province also lacks plants that produce polyethylene resin and has to depend largely on state allocations and imports. In order to change the situation of shortage of polyethylene plastic sheeting for the raising of seedlings, it is suggested that relevant leadership departments at all levels give serious attention to doing a good job of production, supply, and marketing work in this regard.

EXPERTS PROVIDE POINTERS ON COTTON PRODUCTION

Xian SHAANXI RIBAO in Chinese 1 Mar 82 p 2

[Article by Li Xiaosheng [2621 2400 3932]: "When Peasants Grow Cotton Science Has to Be in Charge. Provincial Agricultural Commission Invites Experts to Discuss Technical Problems in Cotton Production"]

[Text] Recently the Provincial Agricultural Commission invited cotton experts to conduct a symposium, and listened to sensible suggestions from the experts on how to do a good job of this year's cotton production and on long range problems in building cotton production bases.

At the symposium the cotton experts recalled the long history of cotton production in the province, and particularly analyzed the status of cotton production during the past several years. They agreed that the province's central region is a very good cotton producing area. The reason cotton yields are low and inconsistent are, first of all, insufficient technical understanding of cotton production. Many effective scientific techniques have yet to be promoted to wide area production. Second is insufficient attention to unfavorable factors in an otherwise advantageous natural environment, which causes passivity in production. For example, the central part of the province is dry during spring and the soil lacks moisture. During the summer, drought is serious, and in the fall there is too much rain. This means that after the cotton has been sown, full stands are impossible; during summer heat boils are few; and in the fall bloom, numerous boils rot. Consequently the cotton experts believe that in order to make cotton production in Shaanxi Province take off and catch up with or overtake advanced national levels, it is necessary to make full use of the dynamics of scientific techniques to surmount climatic changes that are unfavorable elements in cotton production.

But just what measures should be given attention in the scientific farming of cotton? The experts noted the following: 1. Need to nurture soil fertility. For the past several years, soil fertility has been insufficient in the province's cotton growing areas. Its organic content has been overly low to the detriment of cotton growth. Henceforth, all communes and brigades are to adapt general methods to local situations in a large scale return of stalks and stems to fields, growing to green manure, the greater fertilization with barnyard manure. 2. Energetic promotion of 1155 fine cotton variety. 1155 cotton is a high yield, disease resistant fine variety suited for widespread growing in the province's cotton growing areas. While promoting its cultivation, all jurisdictions should actively propagate seeds. 3. Rapid promotion of cotton growing methods of close planting of low plants and growing of seedlings for transplanting. The techniques of close planting of low plants and growing of seedlings for transplanting can bring about early budding, early blossoming, early fruiting, and early harvesting of cotton to get around the many disadvantageous factors resulting from weather changes. They are a new way to get consistently high cotton yields. 4. Step by step directed use of plastic mulch planting methods for the gaining of experience, and then extending it to use over wide areas. 5. All jurisdictions are to take vigorous action to train a technical corps for cotton production. The experts also stressed that all cotton growing areas should act quickly to painstakingly ready the soil in order to improve cottonfield quality. They should organize manpower to select seeds and to conduct experiments on budding to obtain full stands.

This symposium was sponsored by the Provincial Cotton Institute. Participants in the symposium included experts and some cotton technicians from the provincial advisory unit on cotton techniques.

SUMMER GRAIN PROCUREMENT QUOTAS OVERFULFILLED

Jinan DAZHONG RIBAO in Chinese 2 Jul 82 p 1

[Article: "Tai'an, Heze, Zaozhuang, and Linyi Overfulfill Summer Grain State Procurement Quotas. Correctly Handle the Relationship Among the Three, and Actively Support Building of the Four Modernizations"]

[Text] As of 27 June, Tai'an Prefecture had sent to storage 281.5 million jin of wheat procured by the state for a 1.5 million overfulfillment of the state summer grain requisition procurement quota, and 33.6 million jin more than last year.

In order to do a good job of state summer grain procurement work, all levels of CCP committees and government in this prefecture diligently strengthened leadership. The prefecture sent a total of somewhat more than 300 cadres down to the grassroots levels to supervise and give impetus to inspection work, to help do a good job of state summer grain procurement and distribution, and to indoctrinate cadres and the masses in strengthening their national concept to give more and better grain for support of the building of the four modernizations. Wenyang Commune in Fecheng County joyously harvested a bumper crop from 52,000 mu. Within 10 days time, it turned over to the state 13 million jin of wheat, overfulfilling by 5.7 million jin its grain contract procurement quota for the year as a whole from a single crop. The four plains communes of Chengguan, Huqu, Pengji, and Shahezhan in Dongping County harvested a bumper summer grain crop this year and sold a total of 26 million jin to the state, overfulfilling 1.3 times its grain contract procurement quota for the year as a whold from a single crop.

As of 28 June, 146 million jin of wheat had been procured by the state and placed in storage in Heze Prefecture in overfulfillment of the state procurement quota handed down by the province.

Heze Prefecture brought into full play the enthusiasm of both the collectives and individual commune members, and struggled unremittingly against drought to win a bumper summer harvest. The summer grain state procurement quota assigned Heze by the province this year amounted to 145 jin. This figure was double last year's summer grain state procurement quota of 65 million jin. The Prefecture CCP Committee and government administrative offices conducted indoctrination of the broad masses of rural cadres and commune members in love of country, love of collectives, and love of socialism. The broad masses of cadres and commune members indicated, one after another, that "formerly when we sustained disasters, fraternal prefectures energetically supported us; now we can tighten our belts a little to support people in disaster areas." This year Huangduiji Commune in Yuncheng County harvested a bumper crop and turned over to the state 3 million jin of wheat, which was 2.2 times the total amount of wheat turned over to the state for the past 2 years, and represented a contribution of 103 jin per capita. Four production teams in Suge Production Brigade, Sunmiao Commune, Chengwu County sold the state 37,000 jin of wheat, fulfilling in a single season state grain procurement quotas for 3 years.

As of 27 June, Zaozhuang City had put into storage 139 million jin of summer grain in overfulfillment of state procurement quotas issued by the province.

The 1.72 million mu of wheat that Zaozhuang City planted this year was hurt by serious drought. Because of the very unbalanced situation of bumper and lean years in wheat production, this city appropriately readjusted the state procurement quotas for each prefecture and county. Some of the cadres and masses in bumper harvest units indicated their desire to turn over to the state more and better quality grain in a genuine action in support of national construction. After Taierzhuang District had overfulfilled its original state procurement quota of 15 million jin, it took the initiative in shouldering the 7 million jin quota of units having reduced outputs. Throughout the city a large number of contributions averaging 1,000 jin of grain per capita or peasant households making contributions of 4, to 6,000 jin of wheat appeared.

As of 30 June, Linyi Prefecture had turned over to the state more than 253 million jin of summer grain to overfulfill its quotas for this year for delivery of summer grain to storage.

This year this prefecture's wheat was subjected to serious drought and hailstone attacks. Some counties and communes and reduced yields. All counties and communes followed a spirit of using the bumper to supplement the lean for active fulfillment of state procurement quotas. Tancheng, Cangshan, Linyi, Ying, and Linshu counties, located on the plain and having relatively good harvests, took the initiative in turning over more and better grain to the state. Within a period of only 7 days, Cangshan County turned over more than 25 million jin.

SCIENTIFIC TECHNIQUES FOR GROWING COTTON OUTLINED

Jinan DAZHONG RIBAO in Chinese 5 Mar 82 p 1

[Article by Wang Zhengping [3769 2973 1627]: "Take More Action and Give Attention to Solution of Three Kinds of Technical Problems Is Recommendation of Provincial Cotton Institute Experts on How to Win an Even Larger Bumper Cotton Harvest This Year"]

[Text] In a recent report to provincial government leaders, Provincial Cotton Institute experts made the following suggestions. In order to win an even larger bumper cotton harvest this year, more action has to be taken on the basis of existing techniques. Particularly required is a focusing on weak links to solve conscientiously the following technical problems:

1) The problem of mongrelization and regression of seeds. The rapid popularization of Lumian No 1 played a tremendous role in increasing the province's cotton yields, but it also occasioned problems in the mongrelization of seeds. Surveys show that during the past 2 years varying degrees of variation and regression have occurred. In some field plots, altered plants amount to as much as more than 80 percent, which not only causes very great inconvenience in care, but also results in noticeable declines in output and quality. In this regard it was suggested that large scale mass purification and rejuvenation be done, and that seed propagation units or fine variety farms speed up the propagation of pedigree seeds. Right now seed units should intensify care to strictly insure quality. While assuring the fineness of Lumian No 1 variety and making the most of its potential for increased yields, it is also necessary to adapt general methods to local situations for the promotion to cultivation of other fine varieties in order to change the province's reliance on a single cotton variety.

2) Active prevention and control of the two diseases (fusarium and verticullum wilt) and the two insects (aphids and boll worms) that are most damaging to the province's cotton. Three links must be taken in hand in this regard, as follows: 1) A change from single methods of prevention and control to multiple methods of prevention and control, i.e. using agricultural prevention and control as the foundation supplemented by biological prevention and control, with chemical prevention and control as an assurance, the three organically linked, and none of them overlooked. In this way, pesticide use on cottonfields can be reduced by six or seven times for a great reduction in production costs. 2) Replacement and updating of pesticides to increase

effectiveness in prevention and control, and to reduce prevention and control costs and damage done by pesticides. Right now prevention and control of aphids requires use primarily of monocrotophos, and prevention and control of boll worms requires use largely of anliulin [5143 4288 4340]. Currently there is a severe shortage of supply of these two pesticides, which should be quickly studied for solution. 3) Improvement in quality of prevention and control. A good job of surveying fields and making accurate forecasts has to be done. The time for prevention and control measures should be accurately selected, and there should be no blind continuous or large scale spraying of pesticides so as to avoid damage to the ecological balance and increase in prevention and control costs. Sufficiently serious attention should be given fusarium and verticullum wilt of cotton. The successful multiple prevention and control measures against fusarium and verticullum wilt of cotton that the Provincial Cotton Fusarium and Verticullum Wilt Prevention and Control Research Coordination Unit has discovered should be actively promoted. In seriously infested areas, mostly disease resistant varieties should be promoted. In lightly infested areas, mostly crop rotation should be done. In places in which infestations are just beginning, diseased areas should be dug out. In uninfested areas, quarantine should be strengthened.

3) Expanded use of some new farming and care techniques. 1) Interplanting of wheat and cotton. This plays an important role in increasing multiple cropping indeces, and in solving the problem of competition between grain and cotton for land. It may be promoted as possible in places having the conditions. 2) Growing of seedlings for transplanting and use of plastic mulch. Growing of seedlings for transplanting is a successful technique for gaining high cotton yields. In saline-alkaline areas in particular, it plays an outstanding role in assuring full stages and in promoting early seedling development. Plastic mulch has been used over a fairly wide area in recent years for the growing of crops such as vegetables and peanuts, with good results in increasing yields. Last year it was used on more than 200,000 mu of cottonfields in the country for average increases in yields of about 30 percent. After deducting costs, it increases earnings by from 20 to 30 yuan per mu. This year the province plans initially to use it on more than 100,000 mu of cottonfields, and if conditions permit, this area will be somewhat expanded. 3) Use of ethrel to stimulate ripening. Experiments show that after using this technique, pre-frost cotton yields may increase by more than 20 percent at a cost of only about 0.70 yuan per mu. It can increase net income by at least 15 yuan. It is suitable for late ripening varieties and for promotion in high yield cottonfields and on cotton grown in saline-alkaline areas. 4) Leaf spraying of potasssum dihydrogen-phosphate. This is a good way to solve the problem of preventing premature deterioration of cotton plants in fields lacking sufficient phosphate fertilizer. On cottonfields seriously lacking in phosphate, it should be sprayed two or three times during the growing season. It will increase yields by a general 10 percent or so, or by as much as 20 percent at a cost of only about half a jin of ginned cotton per mu. 5) Control of growth with suojiean [4799 4634 1344]. Suojiean is a growth regulator,which plays a definite role in controlling rampant growth of cotton plants when the soil is very futile and water abundant. Experiments show that use of this technique can increase yields by 20 percent as compared with like cottonfields where it is not used.

APPLICATION OF SCIENCE, TECHNOLOGY IN AGRICULTURAL DEVELOPMENT DISCUSSED

Beijing ZHONGGUO NONGKEN [STATE FARMS & LAND RECLAMATION IN CHINA] in Chinese No 3, 1982, pp 26-27

[Article by Mao Naishun [3029 0035 5293] and Ying Anli [2019 1344 3810]: "Problems Concerning the Intensive Farming and Land Reclamation in Xinjiang"]

[Excerpts] During the readjustment of the national economy, state farms must count mainly on their inner strengths for expanded reproduction. In other words, they must strive to raise the level of intensified farming on the basis of their present production conditions.

Intensified Farming Is the Path that the Farms Must Follow in Developing Production

Although land resources are abundant in Xinjiang, land benefited by water conservancy projects is limited. Therefore, resources must be concentrated on improving the existing arable areas. Through the adoption of intensive farming, not only can the utilization rate of land be greatly improved, but it can also, improve that of water. For example, by using plastic sheets in planting cotton and by using 445 cubic meters of water or 140 cubic meters of water more than necessary per mu of land, Farm No 3, Team 10 of Regiment 148 has more than doubled its per mu output of unginned cotton to 230 jin and increased the utilization rate of water by nearly 100 percent.

At present, there is a tremendous surplus of the labor force engaged in land reclamation in Xinjiang, and, in addition there is a great natural growth rate each year. The problem caused by this unemployed labor force cannot possibly be resolved by extensive expanded reproduction at present. This situation has forced us to accelerate the development of intensive farming.

Xinjiang is an agricultural region that can be a high producer, and the per unit yields over a large area of paddy rice, wheat and unginned cotton have exceeded 1,200 jin, 800 jin and 200 jin respectively, every year, so it is perfectly suitable for the development of intensified agriculture. For the time being, many local farms have proceeded from actual conditions to overcome their weaknesses and to bring their superiority into play in an effort to raise the level of their intensive farming. The following are statistics on levels of achievement by 15 farms in 1980:

Allocations of Capital, Expenditures, Income, Profits Recorded by Farms Claiming Over 1 Million Yuan in Profits Each in 1980 Units: mu, yuan

Category	Name	Allocations of capital	Income	Expenditures	Profits	Cultivated Area (10,000 mu)
Farms concentrating on cash crops	regiment 129	132.3	89.9	76	12.7	13.38
	regiment 29	149.6	239	179.4	50.82	12.61
	Shihezi General Farm	114.9	139.9	122.13	16.95	25.66
	regiment 30	185.2	223.7	176.41	43.16	7.29
	regiment 150	79.28	141.8	128.7	8.7	18.68
	regiment 149	72.28	112.8	107	6.35	18.62
Industry-oriented farms	regiment 71	140.2	97.16	69.6	17.06	10.2
	regiment 137	402.2	294	211	48.8	2.77
	regiment 36	460	355.8	265.5	50.9	2.58
Farms concentrating on grains	regiment 166	34.29	34.29	25.07	7.29	25.37
	regiment 66	89.8	71.64	56.8	12.4	10.93
	regiment 161	47.5	40.67	28.9	8.74	16.35
	regiment 77	58.49	46.7	30.6	11.3	12.48
	regiment 75	36.5	28.6	23.1	11.2	10.52
	regiment 168	48.56	44.6	35.1	7.24	15.28

This table shows that although investment in each mu of land was high, profits yielded by each mu of land were even higher. For example, profits yielded by each mu of land in areas of Regiment 29, Regiment 30, Regiment 137, Regiment 36 and others were nearly 50 yuan, while profits yielded by each mu of land and recorded by the sixth company of Regiment 26 were 112.4 yuan. This means that farms of all kinds can raise their profits to a new level, no matter whether they are large or small and grow cash crops or food grains as their main products. They have provided important experiences for intensive farming to produce greater economic results.

Intensive Farming Must Emphasize Economic Results

For years, the Xinjiang land reclamation system has developed agriculture by relying mainly on concentrating investments in the establishment of new farms and by increasing output through extension of arable land, that is to say, primarily through extensive expanded reproduction. After the "Great Cultural Revolution," it suffered serious setbacks from the mismanagement of agriculture. In the last several years, although production has revived rather quickly and there have been some advances, the picture remains basically unchanged. From the economic point of view, the returns on investment remain very low.

Compared with 1957, the entire land reclamation area in 1980 saw a decrease instead of an increase in the average value of output and profits per mu of land despite the fact that its investment of manpower was the same, and its investment in terms of horsepower of farm machinery, chemical fertilizer, fixed assets, and working capital was 2.24, 6.04, 2.25, and 1.59 times greater than in 1957 per mu of land. This means that at present, agriculture in the Xinjiang land reclamation area remains in an embryonic and inefficient farming stage. Increased investment in this case will not necessarily lead to corresponding increase in income. This problem caused by failure to raise harvests through extension of production is highly striking. The term "increased production" here means an increase in output which will be made possible by increased investment of capital, manpower and material resources. The term "additional income" here means an increase in the net value of output made possible by increased capital investment. The realization of additional income from increased production is conditioned on the fact that the returns on each investment, in the form of specific value of output, is higher than the investment itself. In other words, the marginal economic returns should be much larger than the investment itself. This reminds us that the collective economical management cannot be construed by anyone as merely a tendency to make as much investment as possible in each unit of land but as an endeavor to reap maximum net profits from minimum investment.

Advanced Science, Technology Is Essential to Collective Economical Management

Collective economical management is invariably inseparable from advanced technology and proficiency in management. The adoption of advanced science and technology is crucial to the realization of increased production and increased revenues on a continuing basis, under the condition of limited investment in the same acreage. The term "advanced science and technology" here refers to matters that are not only technically advanced but also locally applicable and economically sound. These three elements can be combined to produce maximum economic results when they are properly applied. Practice proves that an advanced technology is viable only as long as it is economically sound. The following experiences we have gained are valuable to our future operations.

1) Cropping strategy must be reshaped. For years, various farms have made efforts to reshape their irrational cropping strategy in a way appropriate to the local conditions and in accordance with the principle designed to bring their superiority into play. In this way, they have reaped excellent economic results. Consequently, the cotton acreage increased from 540,000 mu in 1977 to 1.28 million mu of land in 1981. An increase of 750,000 dan in the gross output of cotton can be expected in the future. But an investment of approximately 120 million yuan must be added to the cost of production in order to bring in an additional 160 million yuan in profits. The following is a calculation of economic returns on investments in production of food grains in proportion to economic returns on investment in production of cotton in 1980: the ratio of income per mu of land was 1:3.42; the ratio of cost of production per mu of land was 1:2.08; the ratio of consumption of manpower per mu of land was 1:2.75; the ratio of profits per mu of land was 1:7.46. This means that those areas suited to the growth of cotton crops should be encouraged to grow more cotton crops because doing so will not result in increased investment in capital construction although the cost of production may rise proportionally. This proposal for planting more cotton crops is also in the best interest of various farms because it will prove instrumental in finding outlets for the large unemployed labor force and in increasing the utilization rate of the existing means of production. But this does not mean that Xinjiang can afford to let the gross output of food grains drop at a time when it is still plagued by a lack of communications and transportation. Nevertheless, steps must be taken by Xinjiang to reduce its grain growing acreage and increase its cotton cropping acreage so that it can boost its

revenues enormously, through the execution of a strategy to maintain its gross output of food grains at the present level by means of increasing the per unit output of grains. As soon as this adjustment is made and the level of the collective economical management is raised, the introduction of specialization will become inevitable for various farms to develop their "hot-selling products," just as Regiment 29 has done. This regiment has produced some "hot-selling items" capable of earning nearly 10 million yuan in profits a year as a result of its efforts to introduce the specialized process of production to the growers of grains and cotton crops and the processed enterprises.

2) Advanced technology must be adopted. Before liberation, no cotton crops were grown in the Mahe River Basin area. Following a successful experiemnt with cultivation of this crop, the area has quickly converted itself into an important cotton producing center. In 1980, the cultivation of cotton crops with plastic sheets proved a success. In 1981, some 20,000 mu of land in the area were planted with cotton. In the end, it reaped more than 150 jin of cotton per mu of land, one-third more than cotton crops sown in other farmland. In some plots, the per mu output went up to 300 jin. The technique for growing cotton with plastic sheets will cost 40 to 50 yuan more than previously, but will bring an additional income of over 100 yuan per mu of land. The technique for cultivating cotton crops with multiple plastic layers is an agricultural feat that rivals the work of nature which can function as countless nurseries and water reservoirs capable of prolonging the frost-free period and improving the utilization rate of liquid fertilizer. This technique can be also adapted to growing many other crops.

For the past several years, we have used plastic sheets to prevent seepage, thus cutting to a minimum the expenditure for maintenance of aqueducts and reducing construction costs 60 percent compared to the use of concrete as a means to prevent seepage. This success has cleared the way to prevent seepage on a grand scale. In 1980, 146 kilometers of seepage-proof canals were completed with this technique and in 1981, more was achieved in this regard.

In the course of raising domestic animals, many units have studied the problem concerning the composition of feeds that can bring more meat in return and produce greater economic results.

These examples show that applicable new technology can play a very remarkable role in promoting production. But this does not mean that we can ignore the frequently used technology. At present, we must concentrate on doing a good job of training workers in basic technical skills so that the contingents of workers can quickly raise their technical skills to a new level.

3) It is necessary to increase the application of chemical fertilizers and other locally applicable chemicals for agricultural purposes. A series of experiments show that the consumption of 1 ton of chemical fertilizer will result in an increase in production equivalent to crops grown in 20 mu of land. Recently, the United States has increased its agricultural production by 30 to 40 percent due to the increased application of chemical fertilizers. During the past several years, our consumption of chemical fertilizers, an important factor in increased production, has been rising so fast that the demand for such com-

modities now has far exceeded supply--for example, 16 jin of pure nitrogen and 6 jin of phosphorus are required to increase every 100 jin of unginned cotton in production. This means that relying on the natural fertility of soil to increase production is far from sufficient; in the future, we must increase the production of chemical fertilizers in order to meet the growing needs for expansion of agricultural production on a grand scale.

4) It is necessary to improve the performances of farm machinery. Mechanized farming will have an important role to play in "tapping potential, structural reform and transformation." Now serving land-reclamation and agriculture throughout the region are farm machines totaling 958,500 horsepower which can now do 70 percent of the farming for major crops at a cost of 130 million yuan to the state, equal to 12 percent of agricultural expenditure. They consume large quantities of fuel and other raw materials each year. In the course of increasing production, vigorous efforts must be made to practice energy conservation. To meet the requirements for collective economical management of agriculture, in the future mechanized farming must be geared to serve the purpose of improving land productivity and energy conservation. In the future, the task of laying plastic sheets to pave the way for planting cotton in large areas cannot possibly be fulfilled by manual labor alone. This will require us to overcome technical difficulties in trial-producing plastic sheet-laying machines.

Coordination Between Short-term and Long-range Interests

Agricultural economization is a long-range plan for agricultural development. Whatever we do, we cannot take into consideration merely short-term interests. Nor can we mobilize all our equipment and land resources for just a single short-sighted venture. The management of land reclamation and farms must focus its attention on creating an agricultural production system ensuring high and stable yield, high quality and low material consumption, along with a sound and highly efficient agricultural ecological structure. We must develop agriculture from a broad point of view and build the management of production of agriculture, forestry, animal husbandry, sideline occupations, and fisheries on a scientific foundation. The term "agricultural economization" is not just a reference to the endeavor to increase the per unit output of crops, but the multipurpose utilization of vast acreage or a strategy requiring farms to produce more crops and processed commodities per 10,000 mu of land. We must concentrate on implementing the overall and long-range plans and diversify the economy.

In the long run, agricultural economization should be viewed as a venture particularly emphasizing scientific and technological research and experimentation as well as education in agricultural technology. We must vigorously strengthen leadership over this activity, staff various agencies with enough personnel, increase investment, particularly investment in biological technology, and establish and improve the economic responsibility system associated with science and technology until it becomes perfect. At the same time, the existing force devoted to science and technology should be encouraged to shift its attention to research, experimentation, and the promotion of technology as a measure to enhance the development of science and technology.

SCIENTIFIC FARMING EXPERIMENTAL AREAS HAILED

Kunming YUNNAN RIBAO in Chinese 8 Mar 82 p 1

[Article by Liu Quanjian [0491 0356 0256] and Zhang Hui [1728 2547]: "Results Outstanding From Province's Multiple Experimentation and Demonstration Areas on Farm Techniques. Use of Multiple Techniques For Rapid Development of Agricultural Production"]

[Text] As a result of the joint efforts of the broad masses of scientific and technical workers, cadres, and commune members, outstanding results have been obtained from the nine multiple experimentation and demonstration areas for farming techniques set up in the province since March last year on the basis of natural zones: Experience in the multiple experimentation areas that have been established shows that the close linking of experimentation, demonstration, promotion and training done in the multiple experimentation and demonstration areas for farming techniques has blazed a new trail for intensifying the spread of scientific and technical results, for developing scientific research, and for advancing agricultural production.

Last year Yunnan Province set up multiple experimentation areas covering an area totaling 278,490 mu in the nine counties and prefectures of Dali, Baoshan, Tengchong, Lincang, Mengzi, Zhaotong, Chuxiong, Guandu, and Menghai. Technicians and local cadres and commune members participating in the work of the multiple experimentation areas comprehensively applied their experiences in increasing yields and scientific and technical achievements as techniques for the promotion of fine varieties, sparse sowing for sturdy seedlings (including the use of plastic film in raising seedlings), planting as early as possible, close planting in rows, scientific fertilization and watering, and multiple measures for the prevention and control of diseases and insect pests.

Tremendous Increases in Grain Output. The multiple experimentation areas increased output of grain by a total of 29.82 million jin for yields averaging 107 jin per mu. The rate of yield increase amounted to 15.38 percent. Fengyi Commune in Dali County, which has always been a high yield area, last year had rice yields of 1,035 jin per unit of area over an area of more than 36,000 mu in the multiple experimentation area. This represented an 85 jin per mu increase over 1980. The intermediate yield Guandu area's somewhat more than

33,000 mu multiple experimentation area produced yields per unit of area that increased from the 753.2 jin of 1980 to 908 jin for an increase of 147.6 jin per mu, a 19.6 percent increase. In Menghai County, where yields have always been low, the 40,100 mu multiple experimentation area last year produced rice yields of 664.4 jin per unit of area, which was a 255.14 jin or 62.34 percent increase over 1980.

Further Research on Development of Results in the Course of Promoting Scientific and Technical Results. While promoting integrated use of the results of multiple techniques, individual multiple experimentation areas also conducted confirmatory experimental research in how to develop further integration of multiple techniques, which accumulated materials for the standardization of integration of multiple techniques. On the basis of spread of multiple techniques, the Baoshan multiple experimentation area, for example, centrally arranged for a 500 mu field plot to be used as a fine varieties area for experiments on seedling quality, extent of close planting, and fertilization methods. As a result of the experiments, verification was obtained and data accumulated on suitable areas for different fine varieties and different kinds of farming and care methods to be used. It provided a basis for future use of the integration of multiple techniques more suited to local natural conditions and for their standardization in the development of existing results.

Training of Technical Forces and Spread of Scientific Knowledge. In the course of experimentation, demonstration and promotion of scientific and technical results, each multiple experimentation area also trained technical forces for rural villages in various ways, spread scientific knowledge, and established a mass technical mainstay cadre corps. They trained a total of 10,000 farm science personnel including production brigade and production team leaders, spending more than 200,000 yuan for training. Looked at in terms of economic benefits, this investment of more than 200,000 yuan in intellect increased grain output by more than 29 million jin for a 1:10 ratio, meaning that for every yuan invested, 10 yuan worth of benefits were obtained.

In order to improve the multiple experimentation areas further, the Provincial Academy of Agricultural Sciences, the Provincial Science Commission, the Provincial Agricultural Commission, and the Provincial Department of Agriculture recently jointly convened a Provincial Multiple Experimentation Area Summarization Conference, which planned for an increase of the multiple experimentation area to 11 sites this year, with a more than 300,000 mu increase in area. Plans call for operating the experimentation areas primarily for the development of research. Over the near term, emphasis will go to grain with gradual development into economic diversification. Later on they will become experimentation and demonstration areas for all around development of farming, forestry, livestock raising, sideline occupations, and fisheries, making them centers for experimentation, demonstration, promotion and training for all of the province's natural areas.

I. GENERAL INFORMATION

WAYS TO ASSURE WATER TO BEIJING, TIANJIN SUGGESTED

Beijing RENMIN RIBAO in Chinese 18 Jul 82 p 3

[Article by Lu Yazhou [7120 0068 3166] and Gu Dingfa [7357 1353 3127], of the Natural Resources Comprehensive Study Commission, Chinese Academy of Sciences: "Six Suggestions For Assuring Water to Beijing and Tianjin Municipalities"]

[Text] Why has there been a water shortage in the Beijing-Tianjin area for the past 2 years? The continuous drought since 1980 is, of course, one reason, but more important reasons are inappropriate use of water and lack of serious attention to the construction of water sources. If the conflict between supply and demand for water resources in Beijing and Tianjin are to be fundamentally solved, in addition to the strengthening of management over the use of water, the following six tasks must be emphasized.

1. A Good Job Must Be Done of Building Water Resources, With Planning as a Whole for Water Use in Upper and Lower Reaches

Beijing and Tianjin are located on the lower reaches of the Hai He where the building of water sources must proceed from overall arrangements for the entire river basin. During the 1950's, water resources were very good in Tianjin. However, since 1958, many reservoirs have been built on the upper reaches of the Hai He, and on the middle reaches farmland irrigation has developed over large areas. By the 1970's, the volume of water on the lower reaches had been reduced to 2 billion cubic meters, only one-fourth the volume of the 1950's. During the 1960's, Tianjin depended for its supply of water on the Miyun, Gangnan, Huangbiya, Wangkuai, Xidayang, and Jiucheng reservoirs. Later on, except for the Miyun and Guanting reservoirs, the reservoirs ceased to provide water, with the result that Tianjin gradually experienced a water shortage. Today, 18 oarge and medium-size reservoirs have been built on the upper reaches of the Ganting reservoir, causing a gradual reduction in the volume of water on the upper reaches and causing difficulties in control and use of Guanting reservoir.

In order to assure water for Beijing, if further development of water resources is to be carried out on the upper reaches of the Guanting and Miyun reservoirs, overall planning has to be provided on the principle of concurrent concern for the upper and lower reaches. In addition, both the Beijing and Tianjin areas must give attention to the building of their own sources of water, carrying out planned construction of water storage and water diversion projects to increase water sources.

2. Supply of Water for Urban Life and Industry Must be Separated From Supply of Water for Agriculture

Water used in Beijing and Tianjin is used mostly for daily life, industry, and agriculture. Agriculture uses the largest amount, taking 65-75 percent of the total. Only 4-7 percent of the total voluem is used for daily life. Water supplied to urban areas of Beijing and Tianjin from fairly large water sources such as the Miyun, Guanting, Yuqiao, and Panjiakou reservoirs has to traverse vast farmlands, and without the necessary management and engineering measures, it is very difficult to assure the cities a supply of water. Therefore, in order to assure normal water supply to the cities for daily life and industry in years of particularly serious drought, their supplies should be separated from those of agriculture, and an independent system for supplying water for urban life and industry must be built gradually to prevent competition from agriculture for water.

3. Sensible Management of the Use of Large Resevoir Water Resources

The Miyun reservoir is a large reservoir that has served to regulate water for many years. It is one of Beijing's dependable sources of water. However, some problems currently exist in the equitable allocation of water from reservoirs. For example, in working up flood plans, no investigation or study of units using water is made; distribution plans are made solely on the basis of the amount of water in the reservoirs. Sometimes plans allow for the use of whatever water is in the reservoirs, so that reservoirs are unable to play a genuine role as regulators over many years. The Guanting reservoir was also once a large reservoir that regulated water over many years. However, as a result of serious erosion on the upper reaches and excessive accumulations of silt in it, the ability of the reservoir to regulate has declined. In the future both the Miyun and Guanting reservoirs should equitably allocate water, and their upper reaches should be designated water conservation forest preserves for genuine water and soil conservation to reduce silting of the reservoirs.

4. Vigorous Promotion of New Techniques for Farmland Irrigation

During the past several years, spray and drip irrigation have developed in China, but area in which spray and drip irrigation is used is still less than 2 percent of the effective irrigation area. In the Beijing-Tianjin area it it even less: only 0.6 percent. Spray and drip irrigation saves 40-60 percent of the water required for flood irrigation. Currently, agricultural use of water in Beijing and Tianjin amounts to 4.5 billion cubic meters annually, and the effectively irrigated area is 70-80 percent. If spray and drip irrigation were to be used on 70 percent of the vegetable fields and 30-40 percent of the grainfields in the irrigated area, a saving of at least 1.5-2 billion cubic meters annually could be effected. This amounts to the total volume of water used by Beijing for 1 years for daily life and industry.

5. Improvement in Multiple Utilization Rate of Water Used by Industry and Restriction of Development of Industries Consuming Large Quantities of Water

Many representative examples exist in China of conservation of water by industry. In Dalian, for example, the recycling rate for cooling water already stands at 88 percent, and the multiple utilization rate for water used in industry is 75 percent. At present the multiple utilization rate for water used in industry in Tianjin is 50 percent; in Beijing, it is 40 percent. Consequently the potential for continued development of water conservation by industry is still very great. About 70 percent of all water used in industry is for cooling, but among Beijing industries, the recovery rate for cooling water is only 40 percent. Annually about 200 million cubic meters is discharged into sewers. This water has been changed only a little, except that its temperature is somewhat high. All that is needed is the building of cooling equipment and it can continue to be used. In future, the distribution of industries in both Beijing and Tianjin must proceed from local water source realities. There must be little or no building of heavy industries or chemical industries that consume large quantities of water.

6. Readjustment of the Structure of Agriculture and Reduction of the Rice Growing Area

Precipitation in the Beijing-Tianjin area is between 500 and 700 millimeters per year. Development of agricultural production must proceed from this fundamental natural circumstance. Every mu of paddy rice requires 800 cubic meters of water, and if the growing of paddy rice is not rooted in local water resources, there is no use expecting that water will be diverted from elsewhere. Furthermore, rice grown in the Beijing-Tianjin area is prone to damage from low temperatures, so yields are not sufficiently consistent. Therefore, the rice growing area should be limited in the Beijing-Tianjin area, where water resources are not abundant. Instead, more drought-tolerant crops should be grown; otherwise every time there is a drought year, agriculture will "fight for water" with the cities.

REVIVED EMPHASIS GIVEN PLANTING OF PULSES

Lanzhou GANSU RIBAO in Chinese 23 Jun 82 p 1

[Article: "Province Expands Pulse Crop Area This Year. Development of Pulse Production To Promote Benevolent Cycle in Agriculture"]

[Text] A provincewide conference on pulse production concluded in Lanzhou on 20 June. The correspondent obtained the following from this conference: This year the area throughout the province sown to various kinds of pulse crops will be 3.79 million mu, a somewhat more than 200,000 mu increase over 1981. This provides a fine foundation for revival of the traditional crop rotation system, for a combination of use and nurture of the soil and a combination of farming and livestock raising.

During the past 2 years, with implementation of self-determination for production teams and increased inprices paid by the state for the purchase of soybeans and broad beans, enthusiasm among the broad masses within the province for development of soybean production has remarkably increased, and readjustment of crop patterns on the basis of local conditions has begun. The traditional crop rotation system has been revived, and the area sown to pulses has risen year after year. In drought stricken Dingxi Prefecture in central Gansu, for example, which had been "shot to death" for a time, the fame of flat beans has been restored, and the area sown to peas and flat beans has increased very rapidly. This year the area sown to peas and flat beans in the prefecture has been enlarged to 1,142,600 mu, 54 percent more than in 1978 and almost an all-time high. Tianshui and Wudu, the principle soybean producing prefectures in the province have multiple cropped soybeans over wide areas. This year the multiple cropped and intercropped soybean area amounts to more than 300,000 mu, which is more than 60 percent of the total soybean growing area of the province. Linxia Hui Nationality Autonomous Zhou has devoted attention to broad beans as a "hot selling" product for export. Since 1977 it has kept working on farm experiments for high yields from broad beans over large areas, and during the past 5 years broad bean yields have averaged about 340 jin per mu, which is higher than for wheat. On high yield farm experiment fields, yields averaged around 800 jin per mu.

Following analysis and study, comrades attending the provincewide conference on pulse production acknowledged that Gansu Province has a long history of farming soybeans, and that revival and development of pulse crops is an effective way in which to promote a benevolent cycle in agricultural production. Inasmuch as soybean crops in the province have everywhere been carelessly grown, varieties mongrelized and degenerate. and yields both low and inconsistent, everyone acknowledged need to promote advanced experiences for increasing yields and to devote efforts to improving yields per unit of area. First it is necessary to give serious attention to breeding of soybean varieties and to introducing varieties from elsewhere, to establish and perfect a pulse crop fine variety propagation system and, at the same time, to change the farming method of "no fertilization of bean fields but looking to heaven for help." Farming techniques have to be improved, fertilizer used, and prevention and control of diseases and insect pests and field care intensified. Furthermore, research on pulses and technical promotion work has to be strengthened.

AGRICULTURE'S NEED FOR GRASS, FORESTS IN GANSU UNDERSCORED

Lanzhou GANSU RIBAO in Chinese 17 Jun 82 p 1

[Article by Letter Writer Feng Jixin [7458 4764 2450]: "Economic Effectiveness Is Also a Core Question in Agriculture"]

> [Text] Editor's Note: On 13 May, Comrade Feng Jixin wrote a letter to the Dixgxi Prefecture CCP Committee in which, on the matter of the planting of grass in Dingxi Prefecture, he emphasized that economic effectiveness is likewise a core question of general significance in agriculture. The letter is published below. All jurisdictions should undertake investigation and study and summarize the lessons of experience to do a good job in accordance with the principle of improved economic effectiveness of planting trees and growing grass, and to do a good job in every aspect of agricultural production.

Dingxi Prefecture CCP Committee:

After reading in GANSU RIBAO, a reporter's article titled, "Status and Problems in Growing Grass in Dingxi Prefecture," I felt the problems raised deserved our attention. It seems that economic effectiveness is not only a core question in industry, but is a core question in agriculture as well. In agriculture, including the planting of trees and growing of grass, it will not do to give no concern to economic effectivness.

In Dingxi Prefecture, the greatest threat to agriculture is multiple drought disasters. Here ground cover is scarce, the climate arid, and erosion serous, which has meant that for a long time agriculture has been in a vicious cycle. Reasons accounting for this situation are numerous. There are both profound historical reasons and genuine work problems, but most important is the contravention of natural laws and destruction of the ecological balance. This has included a plundering of nature, reckless felling of forests, and ill-advised clearing of land that has brought about soil erosion and loss of soil fertility leading to increased frequency of drought disasters, etc. Therefore, if this problem is to be solved fundamentally, it will be necessary to persevere in energetic planting of trees and growing of grass, to develop the livestock industry, and to increase organic fertilizer, plus building some projects in a planned way, things such as building of terraced fields and building water conservancy projects. In this way, production conditions can be gradually fundamentally transformed to turn the vicious cycle into a benevolent cycle. Therefore, it is necessary to educate our cadres, and particularly leadership cadres above the county level, in the need to clearly establish two concepts and to effect two changes. By this is meant, first, establishment of a concept of large-scale agriculture, and second, establishment of a concept of changing the vicious cycle in agriculture to a benevolent cycle. Sole concern about grain in agriculture has to be changed to concurrent attention for economic diversification, and sole building of water conservancy has to be changed to concurrent attention to water and soil conservation and improvement in ground cover. In these tasks, doing a good job of planting trees and growing grass is the key.

For the past many years the state has provided no small amount of investment for the planting of trees and the growing of grass in the province's central prefecture, but results have been slight. A study of reasons why shows the main one to be that all levels of leadership cadres lack perception of the importance of growing trees and planting grass. They have yet to regard this work as a strategic action for changing the ecological environment and advancing development of agricultural production. In many places the planting of trees and the growing of grass halts at conferences, in planning, or in rhetoric without being implemented at the grassroots or being translated into mass action. There is neither any deepgoing spread of scientific knowledge about the planting of trees and the growing of grass among peasants and helping the masses understand practical difficulties in planting trees and growing grass, nor is there any strengthening of organizational leadership and spread of representative and advanced experiences in the growing of trees and the planting of grass. Napo Production Brigade in Shichuan Commune, Tongwei County is an advanced model for its achievements in growing grass. Since 1963 it has energetically developed the growing of grass and by 1979 there were 600 mu of grass in the brigade. The number of large livestock has grown to 109 head; there were 410 head of sheep and goats, 180 hogs, and the amount of barnyard manure increased fourfold. Output of grain and oil-bearing crops doubled. Grain output averaged 1,000 jin per capita for self-sufficiency with a surplus for 17 years in a row. If such a fine model has remained unpromoted for many years, is this not a question of leadership?

The problems existing in Dingxi Prefecture in the planting of trees and the growing of grass generally apply to the province as a whole. Consequently, genuine attention should be directed to this problem. I suggest the following:

1. Prefecture and county CCP committees should place the planting of trees and the growing of grass on their daily agenda of important things to do. Several times each year they should hold special discussions on tree planting and grass growing work. There should be planning, inspections, and firm attention to implementation for real benefits with no empty talk. There should be conscientious summarization and promotion of advanced models and advanced experiences, attention going to solution of difficulties and problems the masses have in the planting of trees and the growing of grass.

2. There should be special funds devoted exclusively to use as subsidies for afforestation and the growing of grass that should not be spent recklessly or diverted to.other uses. There should be genuine concern for economic effectiveness, every mu planted maturing.

3. Intensification of the spread of knowledge and education as well as technical direction about the growing of trees and the raising of grass. Today, not only do the masses have little scientific knowledge or understanding about the planting of trees and the growing of grass, but our cadres do not know much either. Full use should be made of the role of scientific and technical personnel, and they should be asked to impart knowledge in this regard to cadres and the masses to improve the knowledge of the cadres and masses for a genuine change in their conscious actions.

4. There should be breeding and promotion of fine varieties of trees and grasses suited to local realities. For areas in the central part of the province, drought tolerant, fast growing tree varieties should be selected. In the growing of grass, esparcet [Onobrychis sativa], purple flower alfalfa, shadingwang [3097 2092 2489], and Sudan grass may be promoted. These grass seeds are in fairly short supply, esparcet particularly so. Efforts will have to be made to collect, breed, and import them from elsewhere.

PROVINCIAL CCP OFFICIAL EMPHASIZES PRACTICAL EDUCATION

Lanzhou GANSU RIBAO in Chinese 12 Jun 82 p 1

[Article: "Development of Technical Agricultural Education Is a Top Priority Task in Rural Villages. During Investigation and Study in the Rural Villages of Longdong, Liu Bing Noted That Following Institution of Production Responsibility Systems, Rural Education Will Have To Be Done Well With Serious Attention Given the Spread of Agricultural Science and Technology To Improve Peasant Understanding of Nature and to Improve Natural Abilities "]

[Text] According to a report carried in GUANGMING RIBAO, when Gansu Provincial CCP Committee Deputy Secretary Liu Bing recently conducted investigation and study in Longdong, he noted that following rural implementation of production responsibility systems, rural education will have to be done well with extremely serious attention given the spread of agricultural science and technology to develop peasant intellectual resources.

During mid and late June, Comrade Liu Bing, who has just been transferred from Lanzhou University to Provincial CCP Committee work, went to rural villages to investigate and study. He travelled through seven counties in the old revolutionary base area of Qingyang Prefecture where he visited communes, brigades, and peasants, observing the rural situation.

Liu Bing believes that following establishment of production responsibility systems so that production relationships can be readjusted, it is also necessary to devote attention to development of productivity and to steadily readjust the relationship between man and nature. In terms of the situation in Gansu, two conflicts impair the overall situation in agricultural production. One is the conflict between the need for steady growth of agricultural production and the constant occurrence of natural disasters, and the other is the conflict between improvement in the agricultural labor productivity rate and the peasants lack of scientific and cultural knowledge. Solution to the first of these conflicts entails vigorous planting of trees and growing of grass to increase the forest and grass ground cover rate to improve the ecological environment and gradually realize ecological balance. For the second, the solution lies in firm attention to education and the spread of scientific and technical knowledge about agriculture, and the training of a new generation of cultured peasants who understand technology and who are able to manage.

Liu Bing believes that improvement in the ecological environment is part of the transformation of labor, and that attention to education is part of improvement of the quality of workers. Both of these matters relate to how to understand nature and change nature. He said that looked at in terms of improvement of people's knowledge and improving natural capabilities there is nothing of greater importance for the farflung rural villages than development of technical agricultural education. We have come to realize in the course of investigation that whether in large field production, economic diversification, or the planting of trees and the growing of grass, the kinds of people who do well are of just two kinds. One is the new peasant who has cultural knowledge and a grasp of a certain amount of science and technology. The other is those who, despite their lack of culture, are old farmers with abundant practical experience. Both these kinds of people are able to plan, to farm, and to administer. For example, Zhoujia Commune in Zhengning County has a primary school teacher whose wife is an intellectual youth who returned to the village. In addition to doing a good job of farming the fields for which it is responsible, his family has also learned how to keep bees. The family has raised 20 hives of bees, and last year it earned more than 500 yuan from the sale of honey. This year, in addition to keeping bees, it also used native methods to hatch 300 chicks. In another example, Yiman Commune in Qingyang County has a 62-year-old peasant with much experience in production. In addition to farming the fields for which they are responsible, he and his wife have painstakingly raised long haired rabbits to become a specialized household. Last year they raised 50 rabbits, earning an income of more than 700 yuan from the sale of rabbit fur. As of April this year, their rabbit raising had grown to 72 rabbits, and expected earnings this year will be 1,000 yuan.

Liu Bing said that the foregoing examples show that whether the knoweldge has been learned from books or whether it is the direct experience of peasants, so long as it is demonstrated to be effective in practice, it is scientific and extraordinarily precious. Once a peasant understands science and technology, new productivity can come into being, all agricultural production being transformed thereby.

Liu Bing believes that a current problem is the general lack of peasant knowledge of science and culture. Agricultural science and agricultural production are divorced from each other. Many peasants are still separated from modern science. They do not know what nitrogen, phosphate, potash are, or what ecological balance means. Many places continue to destroy forests to clear land, destroying the vegetation cover and hastening erosion. Agricultural production is still in a vicious cycle. This state of affairs creates a sharp contradiction with the mass peasant enthusiasm that is now surging, and is far from being recognized by people. Right now it is necessary to cry out loudly to the public that simultaneous with the establishment and perfection of agricultural production responsibility systems must come a general increase in peasant scientific and cultural levels, scientific and cultural knowledge being linked to agricultural workers.

Liu Bing said that a fundamental way in which to bring about general improvement in peasant scientific and cultural levels is to take a firm grip on rural education. He said the school attendance rate in Qingyang Prefecture has fallen and there is a great increase in illiteracy. Within the course of a single year, more than 5,000 middle and primary school students in the prefecture dropped out of school. Why is this? Liu Bing does not entirely agree that with the saying that with "peasant household assumption of full responsibility for task completion;" the kiddies went back home to tend the cows and sheep. He said that following peasant household assumption of full responsibility for task completion, some peasants did experience such a need, but that the main reason for the decline in rural school attendance rates lay in education work itself, specifically in education and agricultural production being divorced from each other. Peasants felt that sending sons and daughters to school was of no use and they were not very interested in education.

Finally Liu Bing said that in order to change this state of affairs and make education meet the needs of agricultural production, it is necessary, on the one hand, to devote attention to the spread of education and to all sorts of after hours education, while making up ones mind, on the other hand, to restructure rural middle school education. Rural middle schools and the upper grades of primary schools should increase the number of courses in agricultural scientific and technical information. Some middle schools should be converted to agricultural middle schools, only a minority number being retained as regular middle schools. In this way it will be possible for most students to return to the countryside following graduation with "arms" they can use, able to engage in agricultural production with high proficiency. He said that to take Qingyang Prefecture as an example, annually each county has several hundred or as many as a thousand middle school graduates return home to farm. If all of them had studied a certain amount of farm science, and were able to select fine varieties, to use chemical fertilizers, to use pesticides, to propagate seedlings, to graft, to raise livestock and poultry, their return would be tantamount to several hundred or up to a thousand farm technicians arriving. If each of them attended to production in his own home, that would be in several hundred or up to a thousand households. If these were carried on for 10 to 20 years, every single production team and household would have a mass of agricultural technical personnel. They would be able to spread advanced techniques in scientific farming and economic diversification to every corner. Therefore, we should use strategic vision in dealing with rural education. We should not stint on spending the capital or stint on doing all that is necessary to do a solid job of rural education so that every peasant will become intelligent. When that time comes, our agricultural productivity will produce a quality take-off, everyone's understanding of nature and ability to transform mature will be greatly increased, and the vistas for agricultural production will become broader and broader.

AGRICULTURAL, SIDELINE PRODUCT PROCUREMENT IMPROVED

Guangzhou NANFANG RIBAO in Chinese 4 Jul 82 p 1

[Article: "Improvement This Year in Province's Agricultural and Sideline Procurement Work; Adherence to Planned Economy as the Key With Concurrent Concern For the Welfare of the Country, Collectives and Individuals"]

[Text] The correspondent obtained the following from the provincial Finance and Trade Work Conference that began here yesterday. This year the province's agricultural and sideline products procurement work has shown improvement, beginning a turnaround in the trend of declining procurement of the past several years. Out of 27 varieties of category 1 and caregory 2 goods, the procurement of 16 kinds showed an increase compared with the same period last year.

Between January and May this year, the total output value of agricultural and sideline products procured amounted to 1.712 billion yuan, a 12.3-percent increase over the same period last year. This included procurement at list price amounting to 849 million yuan, a 7.8-percent increase, and procurement at negotiated prices amounting to 863 million yuan, an increase of 16.9 percent. Category 1 and category 2 goods for which procurement increased over the same period last year were foodstuffs, edible oil, sugarcane, lives hogs, aquatic products, jute and ambari hemp, cassia bark, citronella oil, rush bags, moso bamboo, flue-cured toabcco, tea, cowhide, pineapple, lumber, li bamboo [6853 4554], with sugar output, procurement and quantity transferred reaching all-time highs. This is the result of the adherence of the province's rural villages to a program of taking planned economy as the key with market regulation being supplementary, and concurrent concern for the state, the collective, and the individual in agricultural and sideline procurement work.

All jurisdictions have accumulated many fine experiences in the procurement of agricultural and sideline products. In Gaozhou County, for example, the food department adopted "procurement of every hog, making separate final accountings for list price and negotiated price," in the procurement of live hogs. The Lianshan County Supply and Marketing Cooperative adapted general methods to local situations in order to advance development of economic diversification in mountain regions. In Boluo County, the Henghe Supply and Marketing Cooperative dealt in agricultural and sideline products jointly with communes to earn the praise of both agriculture and business.

SOLUTION TO RURAL FIREWOOD PROBLEMS OFFERED

Harbin HEILONGJIANG RIBAO in Chinese 7 Jun 82 p 2

[Article by Engineer Zhao Xitai [6392 6932 3141]: "Speed up Solution to Problems in Energy Use in Daily Rural Life"]

[Text] Severe Shortage of Energy for Use in Daily Rural Life

In recent years it has become harder and harder for the province's rural villages to get firewood. A remark circulates among the peasantry to the effect that "it is not what goes into the pot but what goes under the pot that one has to worry about."

In March 1981, we conducted a survey in Baiquan and Mingshui counties. In neither county did peasant households have firewood for the lunar new year. Shangsheng Commune in Baiquan County has 16 production brigades with a total of 5,450 households of which 11 production brigades containing 3,780 households lacked firewood. Households without firewood for from 1 to 3 months numbered 1,100. Households lacking firewood for 6 months numbered 1,200, and another 1,080 households lacked firewood for from 7 to 8 months. They could do nothing but bear the cold, roll straw into cylinders, gather roots of weeds and grass, and burn ox, horse, or pig dung. Some even shared kangs, rooms, and households.

Reasons contributing to this state of affairs were numerous. The steady increase in rural population: the decrease in cultivated land per capita; the increasing decline in the amount of plant stalks and stems each person receives; the steady expansion of the area sown to economic crops (such as sugarbeets and flax) with corresponding decline in output of stalks and stems; destruction of forests and of grasslands when there is nothing to burn, the greater the destruction of forests the more severe the shortage of firewood, and the more the destruction of forests, the greater the shortage of firewood, as well as the beginning in certain areas of soil desertification; a decline in soil fertility; wanton destruction of the ecology; and continuous depradations of natural disasters are all reasons. Unless ways can be found soon for prevention and control, the consequences will be dreadful to contemplate.

Ways To Solve Rural Energy Problems

1. Change in the Senseless Ways of Using Energy. For a long time, plant stalks and stems have been the major biological source of energy consumed in rural villages. Looked at in terms of rural realities, for a very long period of time in the future stalks and stems and firewood will continue to be the major sources of energy used in daily life. However, at the present time the ways in which energy is used in daily rural life are backward and waste is very great. The thermal utilization rate is only 10 percent. Not only is the energy utilization rate too low, but the nutrient materials (such as coarse proteins and sugars); and the organic matter contained in stalks and stems are burned up, while only some potash fertilizer remains from the nitrogen, phosphate, and potash they contain.

One readily workable and very beneficial way in which to change this form of using energy is to promote use of stoves that economize burning of firewood. When such stoves are used the thermal energy utilization rate from stalks and stems may be doubled. Households that formerly went without firewood for 5 to 6 months each year would have just about enough to burn.

In order to get full use out of stalks and stems, efforts will have to be made to realize optimum energy use methods. Use of stalks and stems as fooder for the feeding of livestock and poultry and then using their dung to produce methane gas, followed by use of the organic nitrogen, phosphate, and potash as fertilizer is one way.

Through such utilization, the thermal utilization rate can reach 60 percent, and nutrient materials and organic matter, nitrogen, phosphate, and potash all are used to the full, plus many agricultural and sideline products are provided humanity.

2. Growing of Firewood Forests. Since ancient times, firewood forests have been a traditional energy source for peasant families. Through the building of firewood forests, not only can tree branches be used as firewood and tree leaves be put into pits to ferment and produce methane gas, but the timber problem can also be partly solved and the ecological balance improved. During the 1960's Mingshui County had a 158,000 mu stand, or an average 4.3 mu per household. Not only did the rural villages have more than enough firewood to burn, but frequently when the weather was right they had bumper harvests year after year. By 1978, however, only 38,000 mu remained, an average of only 0.6 mu per household. There was a serious firewood shortage; drought and waterlogging disasters regularly occurred, and lean harvests were reaped year after year.

In Heilongjiang Province there are barren mountains and slopes, ravines, embankments, and four besides [beside roads, ponds, villages, and houses] suitable for the growing of woodlands where the growing of firewood forests should be vigorously encouraged. Hilly regions should be the major places for development of firewood forests, and some barren mountains, wastelands, and unused flatlands around bodies of water should be designated for afforestation, care, and use of individual commune members. Quick growing varieties of trees should be selected, trees that take only from 3 to 5 years to grow from seeds to mature forests, which would be of real significance in rapidly ameliorating the rural energy shortage.

Zoning Daily Rural Life Energy in Places Lacking Firewood

In proceeding from China's realities to solve the problems of energy in rural villages, one can only rely on local rural development for local use.

Principal rural energy sources are small hydroelectric power, methane, firewood forests, the stalks and stems of crops, small coal mines, solar energy, wind energy, geothermal energy, and human and animal dung. These are notably regional, and their areas of distribution are very uneven. Consequently energy resources in individual areas, possibilities for their development and use, and economic effectiveness must be figured out. Zoning of rural energy resources entails centralized on-the-spot investigation of the regional distribution and extent of use of rural energy reserves followed by the demarcation of various kinds of regions to illustrate the energy structure, state of utilization, and existing problems in different areas, and proposal for key ways, in which to further develop and use energy resources. Doing this work well holds major strategic importance for accelerating development of agricultural production and improving the peasants' livelihood.

IMPROVEMENT OF WATERCOURSE MANAGEMENT HIGHLIGHTED

Harbin HEILONGJIANG RIBAO in Chinese 2 Jan 82 p 2

[Article by Heilongjiang Provincial Water Conservancy Bureau Engineer Liu Jincheng [0491 6930 2050]: "A Good Job of River Course Management to Increase River Flood Prevention Capacity"]

[Text] Historically speaking, Heilongjiang Province has frequently had flood and waterlogging disasters, and last year a flood and waterlogging disaster unprecedented since the founding of the People's Republic occurred. Some streams overflowed to wreak havoc, occasioning definite losses for agriculture and the national economy. Consequently, conscientious management of watercourses and consolidation and improvement in their flood prevention capabilities, and full use and protection of soil and water resources has become a current urgent problem requiring solution.

Heilongjiang Province has more than 1,900 streams large and small. On more than 140 streams have been built nearly 9,000 kilometers of protective dikes and numerous control projects. These flood prevention projects have been relied upon to triumph over six major floods that have occurred in the Songhua Jiang, the Nen Jiang, the Hulan He, the Tangwang He, and the Muling He to insure the safety of agricultural and industrial production and the lives and property of the people.

However, as a result of the influence of "leftist" ideology, standards are low and quality poor for many of the water conservancy projects that have been built. Furthermore, construction was emphasized and management slighted, and watercourse management problems are fairly numerous. One is that because of the building willy-nilly of projects that block the flow of water, the ability of watercourses to handle floods has been reduced. Second, the stability of riverbeds has been damaged. Third, flood prevention projects have been seriously damaged. Fourth, pollution of river water is serious. Unless the aforestated problems are solved with all possible speed, agricultural production and smooth building of the two civilizations [material and spiritual civilization] will inevitably be impaired. Should fairly large flood waters suddenly occur, they might easily overflow to bring disaster, causing great damage in every way.

In order to guard against possible trouble, watercourse management must be buttressed. Most important at the present time is attention to the following several tasks:

1. Strengthening of centralized planning and management of water resources and watercourses on a river basin basis. Watercourse management touches on a wide area and numerous sectors. Needed is the establishment on the basis of the area affected of a centralized management organization responsible for watercourse control, flood prevention, development and use of water and soil resources, and other pertinent technical and professional direction.

2. A thorough clearing away of obstacles. Because of the country's present financial and material circumstances, in the short term river flood prevention will depend largely on existing projects and facilities and on the use of the movement and storage capacity of watercourses themselves. Therefore, complete clearing away of obstacles within watercourses to enlarge the section through which flood waters move is a major measure for improving drainage conditions and improving capabilities to move flood waters. All jurisdictions should resolve to do a thorough job of removing obstacles.

3. Strengthening of management of existing flood movement and flood storage areas. Control projects exist on the major rivers of the provinces, and during the high water season, these are relied on largely for the regulation of flood waters in flood water movement and flood water storage areas. In order to assure flood prevention safety on rivers, enclosing embankments, houses, industrial plants, and highways may not be built carelessly in flood movement and flood storage areas, nor can there be dumping of mine tailings, or refuse so that the capability of watercourses to move flood waters and to store food water will be maintained. When necessary, temporary flood water storage areas may be designated, making minor sacrifices to insure major interests.

4. Strengthening of project management. Attention must be given to the maintenance and repair of existing projects and facilities. Destruction of river embankments, and river bank protection work, and the denuding and wanton felling of woodlands that protect embankments is not to be permitted. When illegal destruction is discovered, units concerned should deal with it severely at once.

5. Strengthening of the legal system for good management of watercourses. Watercourse management requires rules and regulations and a system of personal responsibility. Only through legislation is it possible to be able to assure scientific management of watercourses. Regulations on watercourse management have to be formulated so that laws may be used to regulate waters, and so that management is done in accordance with law.

RESEARCH RESULTS ON EARLY WEANING OF SHOATS PUBLISHED

Harbin HEILONGJIANG RIBAO in Chinese 14 Jun 82 p 1

[Article: "Scientific Data Obtained on Feeding Standards For Shoats Weaned Extra-Early. Animal Husbandry Research Gains New Results Under Direction of Professor Xu Zhenying [6079 2182 5391]"]

[Text] Scientific data has been obtained on nutritional requirements and feeding standards for shoats that have been weaned extra-early from the time of birth until they weigh 20 kilograms (from 0 to 60 days old). This research has been under the direction of China's famous livestock expert and Northeast Academy of agricultural Sciencies professor, Xu Zhenying. This is an important finding in livestock research that fills a gap in the formulation of a set of complete feeding standards for live hogs.

China's research on techniques for the early weaning of shoats began in 1980; however, no scientific data had ever been obtained on nutritional requirements and feeding standards for shoats from the time of birth until they weighed 20 kilograms.

Professor Xu Zhenying had formerly done this kind of research work. This particular experimental research began in 1981, and participants in the research included Zhang Rundong [1728 3387 2767] of the Northeast Academy of Agricultural Sciences, and Zhang Guofan [1728 0948 5400], Zhu Shiqin [4281 0013 0530], Xu Keming [1776 0344 2494], and Zhang Hong [1728 1347] of the Hongxinglong Farm Management Bureau. They divided into three groups 36 head of Sanjiang white shoats delivered by Caesarean section to carry out experiments on extra-early weaning, which is to say that following birth, the shoats were artificially suckled. Following feeding and metabolic experimental research, nutritional requirements and comparative values for three feed formulas were obtained for shoats weighing from 1 to 5 kilograms, from 5 to 10 kilograms, and from 10 to 20 kilograms. Results showed the following: The entire group of extra-early weaned shoats suckled on each of the three feeding formulas gained weight fairly rapidly and feed consumption was low. The average weight of shoats from birth until 58 to 60 days old was 26.69 kilograms, a 20.8 percent more rapid weight increase than for shoats naturally suckled by sows under normal conditions. Under natural suckling conditions, the number of deaths during the period immediately following birth of shoats (1 to 7 days) was between 25 and 30 percent of the number born; however when extra-early shoat weaning techniques were employed, the death rate could be reduced to 10 percent, or all could survive. For the group of shoats for which food consumption was low, for each kilogram of weight gain the course protein digested energy consumed was lower than feeding standards for shoats of the same age in the United States in 1979, meaning that under identical conditions of shoat weight increase, food was saved in our experiments as compared with the United States.

The success of this research holds major significance in both livestock research and in live hog production. It can both shorten the time of shoat separation from the sow following birth for an increase in her fecundity rate, and can increase the shoat survival rate. In addition, the success of this research establishes a reliable assurance of pig litters without any specific pathogeny, and blazes a new trail for saving large groups of hogs suffering from illnesses.

HEILONGJIANG

GREATER EFFORTS TO SELL RURAL PRODUCTS URGED

Harbin HEILONGJIANG RIBAO in Chinese 18 Jun 82 p 1

[Article by Commentator: "Broaden Markets for Agricultural and Sideline Products"]

[Text] The Hailun County Poultry Company found markets for greese as far afield as Shanghai, causing rural goose-raising enterprises that were in decline to climb again rapidly. Within somewhat more than a year, the number of geese raised in the county more than doubled. This task was done well and showed the kind of service to agricultural production that the commercial supply and marketing sector should provide, and the warmhearted concern in providing service to the peasants to become prosperous through toil. It also showed the importance of taking the initiative in the marketing of commodities.

The marketing of goods is an extremely important link in our entire socioeconomic life chain. Only when marketing channels are open can production achieve its goal of satisfying the needs of people's daily lives. This can, in turn, give impetus to the prosperity and development of production. If markets for goods are clogged, not only can the people's consumption needs not be satisfied, but a curtailment and regression of production must inevitably occur. Consequently, while giving a high degree of serious attention to the development of production, we must give a high degree of serious attention to marketing work. We must coordinate and match the marketing link to production while at the same time bringing into play an organizational and regulatory role in the quality and variety of goods in plentiful supply and short supply.

As a result of the implementation of the party's various agricultural policies, the rural economy has become increasingly lively during the past 3 years, and products resulting from collective economic diversification and products from commune member household sideline occupations, in particular, have become increasingly abundant. In this process, rural business have made very great progress in the work of purchasing and selling agricultural and sideline products. This has played a very great role in advancing the development of agriculture and in making the peasants prosperous through labor. However, it should be realized that in comparison with development of agricultural production, the marketing link is still a relatively weak one. Among the three categories of agricultural and sideline products that collectives and commune member families produce, some are regularly hard to market. One of the main reasons is that some comrades in the rural business sector have a weak concept of production and do not devote sufficient efforts to organization and direction of production. They often do things in accordance with outmoded and narrow market requirements, and they are unable to take the initiative in conducting investigations far and wide to understand diverse consumption needs in far-flung places. Solution to this problem requires that comrades in all rural business departments and units establish a strong spirit of service to agricultural production and of service to the broad masses of peasants to become prosperous through labor, take full initiative in their work use, their brains, expand their horizons, stride along on both legs, understand all aspects, understand needs of markets everywhere, widen markets for agricultural and sideline products, and use every effort to overcome work difficulties and create convenient conditions for the sale of agricultural and sideline products for the peasants. In reality, despite the very great increase during the past few years in products of agricultural economic diversification and in commune member household sideline products, looked at in terms of the overall needs of the country as a whole, quantities have not been large and still remain small. Were our sales efforts to be like those of Hailun County in the selling of geese, which linked consumers and producers, we would not have to worry about inability to sell. Of course, in both economically diversified and commune member household sideline production, diligent efforts have to be made to organize and readjust to overcome blindness in production that is not in accordance with needs, but this is by no means the problem in most varieties of products. For most varieties of products the problem is still greater production and greater sales.

Certain agricultural and sideline products cannot be sold at once for various subjective reasons unrelated to sales promotion work. These include lack of convenient transportation, shortage of storage facilities, and insufficient processing capacity, etc. Problems in these regards can also be solved with increased effort. In fact, Heilongjiang Province has already taken some effective action to solve these problems, and now what is required is to better carry into effect the measures that have been decided upon. This relates not only to the development of agriculture but to development of the entire national economy as well. It is the common responsibility of all, and all levels of leaders and all sectors of the national economy should genuinely shoulder this responsibility.

Development of rural commodity production is only just beginning. With the bringing into play of the full power of party policies, greater future development will inevitably be greater. We should fully realize this trend and take action in advance to strengthen the marketing link for agricultural and sideline products in every way so that rural business work will meet the new circumstances in development of the rural economy.

RUSH SOYBEAN PLANTING COMPLETED IN ONE STATE FARM AREA

Harbin HEILONGJIANG RIBAO in Chinese 23 Jun 82 p 1

[Article: "Entire Management Bureau Rush Plants 2.5 Million Mu of Soybeans. Wins Victory in Support to Jiansanjiang in Fighting Disaster by Rush Planting"]

[Text] News of victory has been sent on the battle at Jiansanjiang organized by the Provincial Farm Administration to fight disaster through rush planting. Between 1 and 20 June, the entire management bureau rush planted a total of 2.54 million mu of early ripening varieties of soybeans. This amounts to 89.5 percent of the total area sown to soybeans under the management bureau's jurisdiction, and the planting of 750,000 mu more than the planned quota before the battle was joined. The entire state farm and land reclamation area sowed 24.64 million mu of grain and pulse crops for overfulfillment of plan.

Because of serious waterlogging of fields on the 12 farms under the jurisdiction of the Jiansanjiang Farm Management Bureau, sowing could not be done. At the end of May the Provincial Farm Administration decided to mobilize people and horses from everywhere in the state farm and land reclamation area to do battle, which resulted in a reversal of the war situation. For more than 20 days, the commanders locked in battle in the five management bureaus of Baoquanling, Beian, Jiusan, Nenjiang, and Suihua fought with one heart and one mind, closely coordinated, and launched attacks night and day, despite fairly arduous working and living conditions, to complete their mission and win victory. In the course of the battle, an overwhelming majority of motor vehicle units worked in shifts for more than 10 hours daily, and some motor vehicle units put in as many as 23 hours each day. Government organizations, materials, and health departments at all levels operated round the clock without let up, waging war night and day. The Haerbin and Qiqihaer railway bureaus and the Provincial Shipping Bureau as well as Hejiang Prefecture and Tongjiang, Sunke, Jiayin, and Fuyuan counties also energetically supported movement of machinery and seeds, thereby assuring smooth progress in the battle throughout the state farm and land reclamation area. Today the broad masses of cadres and masses in the Jiansanjiang Farm management Bureau's area of jurisdiction are determined to continue unremitting efforts to consolidate the fruits of this victory, to conquer weed growth, and assure sturdy seedlings to win a relatively good harvest this year.

On 21 June, the Provincial Farm Administration held an awards ceremony to celebrate victory at Honghe Farm at which commendations and rewards were handed out to advanced motor vehicle units and persons who had come to notice during the battle. On the following day, the generals who commanded the battle in the five management bureaus set out on journeys and returned with honors.

PROVINCIAL NOTICE ISSUED ON AUTUMN HARVEST

Xian SHAANXI RIBAO in Chinese 6 Jul 82 p 1

[Article: "Provincial CCP Committee and Provincial Government Yesterday Issued an Urgent Notice to All Jurisdictions To Achieve an All-Around Bumper Autumn Harvest"]

[Text] Yesterday, the Shaanxi Provincial CCP Committee and the Shaanxi Provincial People's Government issued an "Urgent Notice on Achieving an All-Around Bumper Autumn Harvest" to all prefecture municipal, and county CCP committees, all prefecture government administrative units, all municipal and county governments, the Provincial National People's Congress Standing Committee party organization, the Provincial Military Region CCP Committee, the Provincial Court, the Provincial Procuratorate party organization, all departments and commissions of the Provincial CCP Committee, all commissions, offices, departments, and bureaus of the provincial government, and provincial people's organizations at all levels. The complete text is as follows (not otherwise published):

This summer the agricultural production situation in Shaanxi Province is very good. The further stabilization and perfecion of production responsibility systems, the arousal of the two enthusiasms, plus fairly timely rains brought a bumper summer harvest of grain and oil and promoted development of economic diversification and industrial sideline production. In most prefectures the summer harvest has been virtually copmpleted by now, so CCP committees and the government at all levels must promptly shift the focus of rural work to autumn production, rapidly start an upsurge to win achieve all-around bumper autumn harvest, and aim for all-around overfulfillment of this year's agricultural production plans. It is in this connection that the following urgent notice has been prepared.

1. Persevere in a program of "positively no relaxation in grain production while actively launching economic diversification." Cadres and the masses must be indoctrinated in firmly establishing an attitude of achieving a bumper autumn harvest of grain and cotton, and an all-round bumper harvest. They should devote strict attention to autumn grain production. In Shaanxi Province, summer grain accounts for only somewhat more than 40 percent of the total grain production, while autumn grain accounts for almost 60 percent. After a bumper summer grain harvest, it is still necessary to

achieve a bumper autumn grain harvest; efforts cannot be relaxed for the major harvest and the greater figure cannot be ignored. In addition to taking a firm grip on grain production, it is also necessary to launch active economic diversification. This is particularly significant for achieving an all-round bumper harvest in agriculture and for increased collective and commune member family earnings. Lopsided notions about concentrating on the summer harvest and slighting the autumn harvest and about single-crop farming must be overcome. All jurisdictions have to adapt general methods to local situations, make the most of their advantages in the farming industry, the breeding industry, and in the agricultural byproducts processing industries, collectives and individuals rising together, increasing earnings by every available means, and using an increase in the ration economic diversification in agriculture for further equitable readjustment of the economic structure of agriculture. It is necessary to firmly establish an attitude of resistance to disasters to achieve bumper harvests and, in view of the possibility that unfavorable conditions such as widespread or severe disasters may occur this year, to fully prepare against all kinds of natural disasters.

A mass campaign to achieve a bumper autumn harvest should be widely launched. The broad masses of rural cadres and commune members should be mobilized to seize favorable opportunities to wage the battle during July, August, and September to achieve an all-time high in total autumn grain output. Wetlands and plains are the major bases ofr assuring a bumper harvest despite drought or waterlogging. They must be painstakingly tended to achieve high yields, efforts being made to harvest an additional 50 jin per my of grain. For drylands, several lines of defense must be established. Where autumn crops could not be planted because of drought, a change should be made to broom corn millet, pulse buckwheat and s-ch crops that have a short growing period. For economic diversification, it is necessary both to tend well the economic crops such as cotton and special forest products, and to energetically raise hogs, cattle, sheep and goats, chickens, rabbits and such livestock, as well as poultry, and to launch other household sideline occupations so that people's earnings will increase by an average of 10 to 20 yuan.

2. We must establish a base of resistance to disasters in order to achieve a bumper harvest. Summer and autumn weather is very changeable. Sometimes there may be drought and at other times waterlogging, both of which pose grave threats to autumn production. All jurisdictions must increase vigilance, fighting drought when it occurs and guarding against waterlogging when it occurs. During the past month or more, the drought situation has been serious in most prefectures. Some places have been unable to carry out autumn planting; in some places sprouting of plants has been difficult; and in some places growth of early autumn seedlings and late autumn seedlings that have just begun to sprout has been checked and some seedlings have died. In places in which the drought is currently serious, every effort should be made to launch work to combat the drought, fighting the drought to sow seeds and to protect the autumn harvest. All kinds of water conservancy facilities should be put to use; management of use of water from reservoirs, ponds, and irrigation ditches strengthened; priorities in water use maintained;

conflicts over water use quickly resolved; solidarity in the use of water, conservation of water, equitable use of water, and scientific irrigation encouraged; and general methods adapted to local situations for small-scale hand watering. In short, every available means should be used to expand the irrigated area. No matter what the form of production responsibility system practiced, all communes and brigades should strengthen centralized management of the use of water. Those who disobey water regulations or damage water conservancy facilities are to be seriously dealt with. Dryland plains and slopes lacking water conservancy facilities should adopt various effective measures to fight drought and preserve soil moisture in order to promote healthy and strong crop growth. At the same time, all jurisdictions should conscientiously put into effect the spirit of the provincial meeting on flood prevention, accelerating the replacement of projects destroyed by water and looking after ailing or dangerous reservoirs and dammed ponds to assure safe passage through the flood season.

3. We must carry out scientific farming of fields and do a good job of caring for autumn crops and special forest products. Tailored care and tailored guidance must be given on the basis of the different circumstances and different crops in wetland, dryland, mountain, and river areas in an effort to achieve all-round balanced increases in output. Where seedlings are missing or the soil has cracked around plants for the late autumn crop, replanting should be done to get full stands. The density of seedlings left standing may be appropriately increased to achieve an equitable plant density. This is the period of vigorous growth, budding, and blossoming for cotton, so individual plant care should be strengthened to assure balanced development of both individual plants and plant colonies. Cultivation, prevention and control of diseases and insect pests, sensible fertilization and irrigation, and timely pruning should be carried out for early, increased and large boll formation. The scientific care of other economic crops and special forest products should also be intensified to assure increased output and earnings. All jurisdictions should devote attention to a group of experimental fields and large-area, high-yield fields in a planned way, combine traditional mass experience and modern scientific techniques, make the most of the role of all levels of agricultural science and technology organizations and of the broad masses of scientific and technical personnel to increase per-mu yields, to set up model fields, and to give incentive to open field production. They should actively promote responsibility systems whereby techniques are linked to output, making sure that quotas are reasonable, measures to be taken are specific, and rewards and penalties are honored.

4. Leadership of autumn production must be genuinely strengthened. All levels of CCP committees and government should diligently put into effect the views of the Provincial CCP Committee on the arrangement of work during the last half of the year, making autumn production their central concern, and making all-round arrangement for all work to be done. All levels in all jurisdictions may, in accordance with concrete circumstances, institute guidance for work in individual areas, on individual tracts, and with individual divisions of labor. Principal leadership cadres at all levels should go down to the production frontlines to understand the circumstances

and solve new problems. They should take in hand the implementation of various agricultural policies, further stabilize and perfect various forms of production responsibility system, arouse the two enthusiasms, emphasize attention to good centralization, with contracting of actual tasks in the system of "double contracting" [the system of fixing output quotas based on households, and the system of peasant households assuming full responsibility for task completion], devote great efforts to the stabilization and perfection of systems whereby production is linked to the workforce and where there is management of fixed quotas, and conscientiously solve existing problems. Major efforts should be devoted to research on scientific agricultural techniques and their promotion, the emphasis being gradually shifted in this direction to learn and apply scientific techniques to advance development of production. There should be widespread launching of competitions for bumper output, making the most of the leading role of skilled production hands and labor models; conscientious revival and reorganization of grass-roots farm science stations and teams; intensification of technical training; promotion of the fruits of scientific research; and improvement in levels of scientific farming. All trades and industries should conscientiously and resolutely use every available means to support agricultural production, contributing their strength to increased output and increased earnings from the autumn harvest. Agricultural departments should acquaint themselves fully with realities and provide practical guidance. Finance and trade departments should vigorously work to do a good job of transporting and supplying materials used in agriculture and industrial goods for the countryside, and of purchasing agricultural byproducts. They should make farm loans available promptly in active support of collective and individual efforts to carry on production. Industrial departments should strive to produce the chemical fertilizer, pesticides, and farm implements that agriculture so urgently needs, and other industrial goods in severely short supply in rural villages. Communication and transportation departments should make priority arrangements for hauling of goods to support agriculture. Electric power departments should equitably arrange the use of electricity in agriculture to assure fulfillment of the urgent needs of production.

BRIEFS

WIDESPREAD RAINFALL--It rained continuously in Shaanxi Province from 7 July until the early morning of 9 July, the largest amount of rain falling in Yulin and Hanzhong Prefectures. Except for Dingbian and Jingbain Counties, all of Yulin Prefecture's 12 counties received more than 20 millimeters of rain. In Hengshan, Jiaxian, Mizhi, Wubao, and Suide Counties, rainfall averaged 40 to 70 millimeters. In Shenmu and Zizhou Counties, rainfall was 97 and 112 millimeters respectively. In some counties of Hanzhong Prefecture and in Hingqiang and Liuba Counties, rainfall was fairly great as well, between 30 to 40 millimeters falling. In Yang County, 77 millimeters fell. In Yan'an Prefecture and in Pucheng and Heyang Counties in Weinan Prefecture, in Bin County in Xianyang Prefecture, in Feng County in Baoji Prefecture, and in Shiquan and Hanyin Counties in Ankang Prefecture, rainfall ranged from 10 to 20 millimeters. However, in most central Shaanxi prefectures and in Shangluo and Ankang prefectures, the rainfall was relatively light, amounting to less than 5 millimeters. The distribution of this rainfall throughout the province was very uneven, but in counties where the amount of rainfall was fairly large, it was extremely helpful in combating drought to protect the autumn harvest. [Text] [Xian SHAANXI RIBAO in Chinese 10 Jul 82 p 1] 9432

RAPESEED PROCUREMENT OVERFULFILLMENT--As of 6 July, Shaanxi Province had overfullfilled its rapeseed procurement quota by 80 million jin and half a month ahead of schedule. The province's rapeseed production bases of Hanzhong Prefecture and Ankang Prefecture each overfulfilled their quotas by 40 percent. Throughout the province a group of peasant households that have sold more than 1,000 jin of rapeseed to the state have appeared. The places that have yet to fulfill quotas are presently giving strict attention to sales to the state, and in the places that have fulfilled quotas masses are continuing to sell surplus oil. ANNUAL HOG SALES PROBLEMS AIRED

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 1

[Text] Recently the Provincial Commerce Department, Finance Department, and Price Bureau jointly issued a notice requiring commercial departments at all levels dealing in foodstuffs to use expansion of pork sales as a major measure for solving the difficulties of the masses in selling hogs.

Measures for expanding pork sales are as follows: Separate sales of fat and lean pork (this measure to be instituted mainly in cities). In counties overstocked with hogs, production teams should be encouraged to slaughter hogs themselves, dividing them for consumption, or the food stations may do the slaughtering and marketing for them. Transfers from surplus to shortage area. Commercial departments dealing in foodstuffs in places lacking hogs may go to counties having a good supply of hogs to buy hogs directly from households raising them, haul them back, butcher them, and sell the pork. In order to encourage such transfers and to solve problems with losses resulting from hauling and marketing, provincial finance and revenue departments have agreed to exempt live hog procurement and marketing links from payment of industrial and commercial taxes up until the end of August. In addition, the notice called upon all jurisdictions to conscientiously clear out their cold storage lockers, to stack produce in them in an orderly way, to empty them of cold storage items that should not be kept, and to clear space so as to be able to increase the procurement and holding in cold storage of more pork.

Both Ji'nan and Qingdao adopted the principle of premium price for premium quality, spearating the lean and the fat pork, and supplying separate cuts of lean pork, pork from which fat had been trimmed, and fat pork. In addition, they continued to supply the "centrally supplied pork" at the formerly retail listed price. Cut up prok prices rose from the prevailing 1.23 yuan per jin to 1.35 yuan per jin; fat pork fell from 1.03 yuan per jin to 0.93 yuan per jin; streaky pork fell from 0.82 yuan per jin to 0.75 yuan per jin; and pork from just behind the head fell from 0.68 yuan to 0.60 yuan. Various kinds of spareribs continued to be sold at prevailing prices. The retail price for pork trimmed of fat with bone in was sold at the same price as the centrally supplied pork with bone removed, i.e. at 1.13 yuan per jin. In this way the overall price for pork was maintained constant. Other cities can follow this method used in Jinan and Qingdao. In the case of counties that had severe drought during the previous period that have large stock of pork on hand, priority should go to making arrangements for state procurement allocations. Integrated meat plants located in counties should actively carry out processing to traim fat and reduce the price for fat to 0.60 yuan per jin, selling it locally. Such lean pork as cannot be sold locally should be sent to cities for sale. In addition to continuing to do a good job of supplying undifferentiated pork, county seats and rural villages are to follow existing regulations to process pork trimmed of fat with the bone in and fat meat, selling the fat and the lean separately. The price for pork trimmed of fat should be based on the prevailing price for undifferentiated pork with the bone in the price being lowered depending on the proportion of fat trimmed and the amount of fat remaining.

Letters to the Editor

[Text] Editor's Note: June and July are the busy seasons for the end of fattening of live hogs and their removal from inventory, and in some of the counties of the province, difficulties have again arisen in the sale of hogs. Recently this newspaper has received letters from various readers that reflect this problem, several of which have been excerpted from publication here. The main reasons for the occurrence of difficulties in selling hogs are overproduction, encumbered channels, and lack of vigorous sales promotion. Between January and May this year, Pork sales in the province declined 20 percent as compared with the same period last year. More than 600,000 fewer hogs were sold, showing that much leeway exists for improvement in the work of buying and selling live hogs.

Right now the weather is sweltering, and some people have urgent need to sell off their hogs. Departments dealing in foodstuffs ought to have a spirit of high responsibility toward production and toward the masses, and strive to expand sales of pork so that sales will stimulate purchases, thereby solving the difficulties of the masses in selling hogs while solving, at the same time, the difficulties some places have in getting meat to eat. Live hog production and procurement is an important matter with ramifications for agricultural production and the people's livelihood. Rural party and government leaders at all levels should be extremely attentive to this matter, regularly concern themselves with it, regularly study it, regularly look into it, and do all possible to solve this problem.

Comrade Editor:

Energetic efforts on the part of the state during the past several years to support commune member development of hog raising endeavors have thoroughly stirred the enthusiasm for hog raising of the broad masses of peasants, and the number raised has steadily increased. Statistics show that in Yishui County the number of live hogs in inventory has climbed from 270,000 head in 1978 to the present more than 350,000 head. Accompanying the rapid development of live hog production has been an ever increasing contradiction of production being greater than sales, and peasant cries of "difficult to sell hogs" have also reached new highs. Every summer, in particular, numerous peasants worry about their inability to sell their fattened hogs. We believe that the main reason for present peasant difficulties in selling hogs is that flow channels are encumbered with the result that frequently one place has much pork while it is impossible to buy pork at another place. Not long ago, Yishui County had too much pork and its cadres, satff and workers twice ate "patriotic pork," while in the Linyi County seat, just 200 li distant, pork was in short supply, and whenever it appeared in markets, it was bought up entirely. Why could transfers not be made from one place to another within the prefecture? We call upon relavant departments to diligently study and solve new problems that appear in live hog production, procurement, and marketing work, and to open, under guidance of the state plan, channels of flow. Food departments should change their style of doing business, set up more network outlets, expand sales, and use sales to spur procurement. We believe that if only all departments take every possible action peasant difficulties in selling hogs can be solved.

Xiang Yujie [4161 3768 2638]

Comrade Editor:

Right now is the busy season for removing fattened hogs from inventory. Here in our village of somewhat more than 300 households, more than 150 head of fattened hogs are waiting to be sold, but the food station says it cannot accept thatmany, and commune members cannot market them by themselves. Many commune members say: It is hard to feed hogs, and even harder to sell them. We hope that departments concerned will take effective action to solve this problem of peasant difficulties in selling hogs with all possible speed.

Houshan Production Brigade, Yuangezhuang Commune, Mouping County

ADVANCES IN FOOD PROCESSING REPORTED

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 1

[Article: "Results Good From Continuous Production to Marketing by Jinan Food Industry. For Past Half Year City's Food Production Capacity Has Expanded, Output Has Increased, Varieties Have Become More Numerous, Quality Has Improved, and the Market Supply Situation Has Clearly Become Better"]

> [Text] Editor's Note: Clear results have begun to show in the continuous production to marketing by Jianan City's food industry.
>
> Food industry production is closely related to the people's livelihood. A good job of food production and accelerated development of the food industry is a common desire and demand of the broad masses of people. Formerly, because of the separation of industry and commerce, production and marketing were disjointed, so the food industry's output was low and quality poor; development was slow and very much unable to meet requirements for constant improvement in the standard of living of the masses. In restructuring the management organization of its food industry, after instituting continuous management system from production to marketing, Jinan City pretty well solved some contradictions and shortcomings in food industry production. This provides some good methods that may be borrowed for development of the food industry.

During the past half year since the Jinan Municipal Food Production and Marketing Compa-y instituted a continuous production to marketing management method, output of foodstuffs has increased, varieties have become more numerous, quality has improved, and market supply has taken a clear turn for the better.

Since its founding in November last year, the Jinan Municipal Food Production and Marketing Company has focused on the backward production, technological weakness, the splintered leadership, and the decentralized management of the food industry. It has spotlighted the two major areas of expansion of production capacity and improving product quality, taking the following several actions:

(1) It has taken the path of "tapping potential, converting, and amalgamating, the state owned and the collectively owned, and the urban and the rural all rising together. By tapping potential is meant the tapping of potential within enterprises through their reorganization and changes in production conditions, increasing colors, styles, and varieties, improving product quality, and reviving traditional name brand products. By conversion is meant the selection of some enterprises that have not fulfilled their quotas for conversion, converting them, in conjunction with industrial reorganization, to food industries to open new production capacity. By amalgamation is meant use of suburban commune and production brigade, and district and street collective enterprise plants, equipment, and workforces to organize diverse forms of integrated enterprises to expand production of popular foodstuffs and foodstuffs that fill gaps. This amalgamation has followed the principles of keeping the enterprises small, keeping them collective, and having a retail outlet at the front of each plant, with production and marketing companies using the contract system for planned, professional, and responsible management. For the past half year, they have exercised responsible management of the production and marketing of pastries, candies, cold drinks, snacks, and fruits. They have carried out a tapping of potential and improvement of six enterprises, have provided for the conversion of five enterprises to the production of foodstuffs, and have operated 33 integrated enterprises, causing production capacity to expand almost fivefold, and styles, colors and varieties to increase by more than 40.

(2) They have devoted efforts to improvement of quality and to the making of name brand foods. For the past half year, they have energetically revived and developed traditional products, and have developed and produced new varieties with a local flavor to satisfy consumer needs in many regards. People have been sent out on 18 individual trips to invite 11 technicians from Shanghai and elsewhere to solve a number of technical difficulties. They have run technical training classes and various kinds of specialized training classes to train more than 250 technical mainstay cadres of various kinds. In addition, they have hired old retired workers and engineering technicians with superb skills from throughout the city to organize technical advisory teams. They have had them act as staff officers in the training of apprentices, and in the development of noted fine quality foodstuffs. Within only 3 months, they have come up with more than 30 suggestions for improvements, they have helped revive 22 varieties of traditional and brand name products, and have introduced and innovated 28 varieties of products, with the result that food production has become diversified, products have a distinctive flavor, and packaging has taken on a gift wrap appearance.

(3) They have based themselves on the longterm, have made the most of strengths, and have established bases for the consistent supply of raw materials. Suburban Jinan communes and production brigades have abundant agricultural byproduct resources, and a vast scope exists for development of foodstuff industries. After establishment of the production and marketing company, it followed the principle of taking as a key link the doing of a good job in using existing resources while at the same time giving attention to the fostering of new resources; of taking development of local special products as the key, while giving attention to the opening of rar materials

bases for popular foodstuffs; of taking development of artificial breeding as the key, while giving attention to development of wild resources for use; of taking organization of local processing as the key, while giving attention to doing a good job of having raw materials go directly into the city, with the planned signing of contracts with counties, communes, and brigades, the opening of joint city and countryside enterprises to give impetus to rural economic diversification and development of processing industries for the very rapid establishment of a group of raw materials bases to create good conditions for the steady development of the good industry.

The Jinan Food Processing and Marketing Company is both an executive management organization and an economic organization. It both manages production and manages raw materials supply and product marketing. Thus it has broken through the rigamarole that has fettered some productivity and has enlivened production and marketing. This year, among the 13 enterprises that are directly subordinate to the company, and among the more than 30 joint enterprises that the company manages, a new atmosphere has occured in which they have vied to understand market needs, to improve their service attitude, to raise operating standards, to improve product quality, and to increase colors, styles and varieties. At the food fair held in April and the children's food fair held in June, all sorts of pastries, candies, drinks, snacks, and fruit manufactures bloomed like a hundred blossoms to dazzle the eyes. The masses said happily, "Jinan's food markets are beginning to look like something to taste like something."

AGRONOMIST DISCUSSES PROBLEMS OF COTTON PRODUCTION

Jinan DAZHONG RIBAO in Chinese 6 Jul 82 p 2

[Article: "Strategic Problems in Shandong's Development of Cotton Production Explored--a Visit with Cao Boqiang [2580 0130 1730], Ranking Agronomist, Shandong Provincial Academy of Agricultural Sciences"]

[Text] During the period when the Huang-Huai-Hai Plains Agricultural Development Academic Symposium was in session in Jinan, the correspondent paid a call on the conference's deputy secretary, Comrade Cao Boqiang, and asked him to talk about strategic problems in Shandong Province's development of cotton production. Cao Boqiang is the ranking agronomist at the Shandong Provincial Academy of Agricultural Sciences and secretary of the Shangdong Agriculture Society, and is an expert who has been engaged for many years in the study of cotton production.

In discussing the province's prospects for development of cotton production, Cao Boqiang said happily that development of cotton is an economic strength for Shandong Province. During the past 3 years, cotton production in the province has developed by leaps and bounds, demonstrating the tremendous role of this strength, and the potential is still very great. Further development of this strength is not only an urgent need for the broad masses of cotton growing peasants, but it is also an inevitable trend in the economic development of the province. Exploration of strategic problems in achieving further development of cotton production must be based on the principle of coordinated scientific and technical, economic, and social development, with the implementation primarily of an intensive development program. In this connection, he spoke first of the problem of further perfection of the distribution of cotton fields. Comrade Cao Boqiang said that as a result of several years of readjustment, the province's cotton field area had expanded from 9.4 million my in 1978 to more than 14 million mu in 1981, and further expansion of the area would occur this year. Right now there is a fair amount of discussion about how to further improve and readjust cotton field patterns. He expressed the view that the ratio between grain and cotton crop areas is closely related to the production level for grain crops, and that the basic point of departure for handling the relationship between these two is to adhere to cotton growing areas growing their own grain to achieve self-sufficiency or substantial self-sufficiency. Under current production levels, the province's economic crop area should amount to about 30 percent of the total cultivated land. In Shandong Province, 80 percent of all cotton fields are concentrated in the four prefectures of Dezhou, Liaocheng, Huimin, and Heze. In these prefectures, there is about 2 mu of land per capita, 20 percent more than the average number of people engaged in agriculture per mu for the province as a whole. However, per-mu grain yields are lower than provincial levels, and the potential for increased yields is fairly high. Considered in terms of developmental strategy, the ratio of cotton fields could be correspondingly somewhat larger. Recently a 2-year survey of production and comparative analysis of 37 cotton-growing counties was conducted, and the results showed that by proceeding frcm adherence to the principle of cotton growing area self-sufficiency, or substantial self-sufficiency, in grain production, the cotton field area in key cotton-producing areas could be about 40 percent of cultivated land, and that in key cotton-producing counties, it should not exceed 50 percent. Considered in terms of cotton field distribution per se, there is still the problem of a proper concentration. Widely scattered cotton fields do not make for the strengthening of leadership and do not favor the spread of advanced techniques. Arranging cotton fields on the basis of soil and climatic area that lend themselves best to the growing of cotton is the most fundamental foundation for improving cotton field distribution. With the rapid expansion of cotton fields in the province, the arrangement of some cotton fields is not entirely suitable. This problem is very deserving of attention.

Comrade Cao Boqiang said that cotton field distribution must be achieved in conjunction with the breeding of fine varieties, with their propagation and spread, and with improvements in the farming system. The growing season for the cotton-growing areas in the southwestern part of the province is about 15 to 20 days longer than in northern Shandong; consequently, both the southwestern and southern Shandong cotton-growing areas might suitably develop some intermediate ripening varieties, and they might properly develop some cotton-growing areas where wheat and cotton are grown in a two-crop system in order to ameliorate the conflict between grain and cotton. Northern Shandong cotton-growing areas are suitable for the breeding and promotion of some early maturing varieties tolerant of salinity and alkalinity.

Next, Cao Boqiang spoke about the problem of increasing cotton field fertility. He said that improvement in cotton field fertility had already begun to be recognized by people, and that fertility of Shandong Province's cotton fields had already begun to improve. However, in terms of cotton production developmental strategy and the need for sustained, consistent and high yields, further effective actions had to be taken for continued vigorous nurturing of cotton field fertility. For large areas, improvement in cotton field fertility is a long-term strategic task; it is not something whereby results can be seen very quickly. Action has to be taken steadily and formed into a system for consistent improvement. Nurturing the fertility of cotton fields must follow the principle of "using the land and nurturing the land and using cotton to nurture cotton," organic fertilizer being most important and chemical fertilizer being ancillary for gradually changing the present tendency of relying primarily on chemical fertilizer to increase output, to the neglect of organic fertilizer, as well as the tendency to emphasize increased yields during the current season to the neglect of the long-term and of methods for improving economic benefits in an allaround way. Cao Boqiang said that people do not yet fully appreciate the full use of cottonseed cake for development of the livestock industry or the accumulation of stable manure to improve soil fertility. At the present time, most cottonseed cake is used for direct fertilization of the fields with only a miniscule amount being used for the feeding of livestock, and this is a very great waste. Experiments have shown that when cottonseed cake is applied directly to the ground, crop use of its nutrients is very low: its nitrogen utilization rate is only 30 percent and the remaining nitrate nutrients are wasted. Were it to be used first for the feeding of livestock and the resulting manure applied to the ground, not only would an increase in protein feed for the livestock result in a saving in grain and a moderation of the conflict between grain and cotton in cotton growing areas, but the livestock industry could also be vigorously developed and the quality of organic fertilizer improved. At the present time, detoxification of cottonseed cake has been substantially solved, and energetic efforts should be made to use it as livestock feed. If this is done, it can be predicted that the province's present cotton bases will simultaneously become livestock bases, with the promotion of tremendous increases in both grain and cotton output following.

The third problem about which Cao Boqiang spoke was the strengthening of scientific research to improve economic benefits. He said that following the Third Plenary Session of the 11th Party Central Committee, the state had instituted policies to encourage development of cotton production. Economic benefits for cotton-growing peasants greatly increased, and this played an important role in the development of cotton production in Shandong Province. However, it must be realized that the current increase in benefits to cotton-growing peasants is attributable, to a very great degree, to price policies, while socioeconomic benefits from the cotton-growing industry per se have yet to be fully realized. He pointed out that in order to increase socioeconomic benefits from the cotton industry, from both a current and a long-range standpoint it is necessary further to strengthen scientific research, to increase cotton growing standards, to lower production costs, and to launch comprehensive utilization of cotton byproducts. Our former research on cotton techniques lay particular emphasis on individual techniques for increasing yields, while increases in cotton output were not commensurate with the value of the material and labor resources invested in cotton fields. This caused a rise in costs and a decline in net earnings. A solution to this problem currently lies in taking a firm hold on the popularization of existing cotton growing techniques. In the future it will be necessary further to intensify scientific research and to improve scientific cotton growing standards. The popularization of scientific techniques requires, first of all, adapting effective cotton-growing techniques and analyzing different levels of production to compile complete technical growing data that are then disseminated in various ways to teh braod masses of cotton-growing peasants for application to production, so as to cut down on blindness in the use of technical measures for a saving in manpower and material resources, a lowering of costs, and an increase in per-mu yields. Long-range thinking requires the enhancement of basic research as well as research on comprehensive techniques for increasing yields. In view of Shandong Province's lack of water resources, insufficient energy, and high cotton field ratio, efforst should be centered on the key matters of increasing the low energy utilization rate, taking firmly in hand the nurturing of soil fertility, scientific use of fertilizer and water, all-around prevention and control of diseases and insect pests, and such problems through organization for a concerted attack. A series of optimum farming techniques applicable to different cotton-growing areas must be gradually explored on the basis of the distribution of different varieties.

In talking about the processing and comprehensive use of Shandong Province's cotton products, Cao Boqiang said definite capabilities exist in the form of equipment and techniques, and crop patterns are also fairly equitable; however, they are very ill suited to the state of development of cotton production. The present situation is one in which the state is unable to recover a substantially large portion of cotton byproducts; large quantities are totally wasted; for those items that are used technology is backward, output is small, and costs are high; many ways of using them have not been exploited, such as the use of cottonseed cake in medicines, in the production of mixed livestock fffes, as a high protein food, and the use of cottonseed oil in the food industry. Research has just begun on some of these applications, but no one is researching most of them. This represents a very great potential, and tapping of this potential has become an inevitability in cotton production. In this regard, it is necessary to take the path of joint endeavors by state-owned enterprises, communes and brigades, and cotton-growing peasants, to expand processing capacity and to improve processing quality in order to recover a comparatively large amount of cotton byproducts. In addition, it is necessary to launch scientific research on areas not being exploited on the basis of realities in Shandong Province for gradual expansion of the scope of comprehensive utilization. Regarding this problem, Cao Boqiang expressed the view that there are currently two tasks meriting special attention. The first is acceleration, strengthening, and improvement of the scientific corps for improvement of production and comprehensive utilization of cotton. At present, Shandong Province has few people engaged in cotton research and the promotion of techniques, and the aging of personnel and outdatedness of their knowledge increases daily. Many research projects cannot be launched. Meanwhile scientific and technical personnel engaged in the processing and comprehensive use of cotton amount to only 0.0025 percent of the total number of employees in this system. Consequently, intensified development of intellectual resources and the adoption of various ways to strengthen and improve this corps is extremely important. The second is perfection of the scientific research system for cotton production and processing for use, departing from the wasteful duplication of scientific research projects and no one working on some tasks. This requires a combination of conscientious scientific and technical, economic, and social planning. Finally, Comrade Cao Boqiang suggested that provincial departments concerned coordinate the scientific research forces in all quarters, formulate "triple combination" plans, take firm hold of key topics, and organize a coordinated attack so that the limited manpower, material, and financial resources may play a comparatively large role and promote the emergence in Shandong cotton production of an inspiring new situation.

WAYS TO DEVELOP WESTERN SICHUAN PLAIN AGRICULTURE EXAMINED

Chengdu SICHUAN RIBAO in Chinese 1 Jul 82 p 2

[Article by Sichuan Provincial Science Commission study team: "Exploration of Ways in Which the Western Sichuan Plain Can Develop Agriculture"]

[Text] The Western Sichuan Plain has fertile soil, temperate climate, copious rainfall, developed irrigation, concentrated population, and sufficient workforce; the conditions for development of agricultural production are comparatively superior. Cultivated land in the 30 counties (or districts) of the plain account for 15 percent of the province's cultivated land area, and the agricultural population accounts for 14.4 percent of the province's agricultural population. Each person farms an average of 1.2 mu, on which largely paddy rice, wheat and rice are produced. This is the main production base in the province for commodity grain, edible oil, and hogs.

Since Liberation, great development has occurred in agricultural production on the Western Sichuan Plain. Nevertheless, development has not been rapid, and some major indicators are still lower than the national level. The main factor affecting the speed of agricultural development of the Western Sichuan Plain, apart from past policy mistakes, has been neglect of the role of scientific techniques. Irrational agricultural patterns and one-sidedness in emphasizing certain grains have blocked full use of natural and social resources and have restricted the bringing into play of the multifunctional effects of the farmland ecological system.

Stress on Advantages of Intermediate Rice Production and Appropriate Expansion of Economic Crops

The Western Sichuan Plain is a famous rice-growing region in China in which paddy rice output in normal years accounts for about 80 percent of the region's grain production for the year as a whole. However, since the 1960's, as a result of excessive expansion of wheat and barley production, followed by the blind development of double rice crops for a period of time, the advantages obtainable from intermediate rice were damaged. In fact, natural conditions on the Western Sichuan Plain are extremely favorable for intermediate rice production. Representative sampling carried out in Wenjing Prefecture shows that for each worker put into paddy rice production, grain output is 23.8 jin, which is 54.5 percent higher than for wheat. For each yuan worth of chemical fertilizer invested, 40.8 jin of paddy is produced, benefits from the investment in fertilizer being 126.7 percent higher than for wheat, and the cost per jin being lower. The net increase in value from paddy rice is 61.60 yuan per mu, 26 yuan and 40.40 yuan higher than for wheat and corn respectively. The economic benefits from intermediate rice are best and the potential for increased yields is great. In 1980, eight counties on the Western Sichuan Plain farmed a total of 2.85 million mu of paddy rice, which accounted for 28.2 percent of the rice-growing area on the Western Sichuan Plain, yields averaging 827 jin per mu. If Western Sichuan Plain paddy rice yields had reached this level or just slightly higher during the past several years, the annual incremental rate of increase for paddy rice would have been 3 percent.

For a long time the Western Sichuan Plain has been in the habit of growing economic crops during its winter crop production season. Economic crops such as rape, tobacco, medicinal herbs, and vegetables account for more than one-third the winter crop area. Crop patterns are rational for "raking in grain in the fall and raking in money in the winter." After the 1960's when only grain production was emphasized, the economic crop area was contracted greatly, to the detriment of increases in commune member earnings. Naturally expansion of economic crops was curtailed by grain output, market capacity, scientific techniques, production conditions, and such factors. State plan guidance had to be taken as the key, and blind action avoided. Nevertheless it was possible gradually to curtail the wheat-growing area somewhat by increasing per-mu yields so as to expand the growing of some economic crops. If it had been possible to further increase per-mu economic crop yields, the economic benefits would have been very outstanding.

Development of Agricultural and Sideline Product Processing and Practice of ComprehensiveUse

While striving to increase agricultural output, it is necessary to institute all-round processing and use of agricultural and sideline products to improve overall economic benefits from agriculture. During the past several years the Western Sichuan Plain has begun to give attention to this problem and has achieved remarkable results. In 1980 the output value from the processing of agricultural products by 30 counties (or districts) came to more than 1.6 billion yuan, or 58 percent of total output value from agriculture. Nevertheless, the all-round processing and utilization rate for agricultural and sideline products on the Western Sichuan Plain is currently relatively low; the colors, styles, and varieties are few, and continued improvement of quality is required. This means that expansion of the scope of processing is necessary, on the one hand, while development of precision work is required on the other, with steady improvement in processing techniques, increase in product competitiveness, and ex pansion of markets for products. Not only is it entirely possible to increase the processing value, but the potential is also very great. For example, a ton of wheat flour costs 340 yuan. When made into noodles, vermicelli, and bread, the output value is increased by 17.6 percent, 35.3 percent, and 3.7 times respectively. Each year following the crushing of oil from rapeseed, more than 300 million jin of rapeseed cake remains. According to measurements made in livestock feeding experiments, the energy derived from the digestion of 1 kilogram of rapeseed is equivalent to that of 0.83 kilograms of corn. The total energy derived from the digestion of rapeseed cake from 30 counties is equivalent to that of 260 million jin of corn, or about one-fourth the corn output of the Western Sichuan Plain. Today, however, only 2 percent is used. Most of its is applied directly to fields, which is an extreme waste. Livestock products from the Western Sichuan Plain are abundant, but the quantity processed is very small and the varieties uninteresting. In the future, it will be necessary to increase the quantities processed and to enlarge the number of varieties. Shifang pressed duck is sold locally at a profit of only 2 yuan; exported it brings 5 yuan. The feathers from 20 to 25 ducks can be processed into a down jacket of high value. One down sleeveless jacket takes 2 liang of down costing 4 to 5 yuan and can be sold abroad for 16 to 19 yuan. The Western Sichuan Plain has many kinds of vegetables and output is high. By vigorously developing vegetable processing, economic benefits can be increased and the conflict between supply and demand during the slack season in vegetables can be moderated. Sizhai and Wanchun Communes in Wenjiang County experimentally produced somewhat more than 100 tons of salty garlic and salty cauliflower for export, thereby increasing their value by more than 30 percent and more than double respectively. Bamboo is very abundant on the Western Sichuan Plain and development of the plaiting of bamboo holds great prospects. In 1980, output value from the plaiting of bamboo in Chongqing County amounted to 5.46 million yuan for a 60-percent profit, each household in the county averaging an increased income of somewhat more than 27 yuan. In 1980, seven [character illegible] in the 13th Production Brigade of Daoming Commune in Chongqing County plaited bamboo with an output value of more than 120,000 yuan, for a fivefold increase in value over the bamboo raw material.

Enthusiastic Encouragement and Support to Peasants for Development of Household Sideline Occupations

Peasant households on the Western Sichuan Plain average in general more than 100 yuan in income from household sideline occupations, of which about 65 percent comes from the raising of hogs, earnings from the farming of private plots and woodland plots amounting to about 20 percent, handicraft plaiting amounting to about 10 percent, and odd-job income amounting to 5 percent. Statistics from 15 counties show that during 1980 peasant purchases of consumer goods averaged 128 yuan per capita, more than 70 percent of which derived from household sideline occupation earnings. Vigorous development of an economy run by the peasants themselves is not only necessary, but its potential is considerable. Private plots in the 30 counties of the Western Sichuan Plain amount to 1.29 million mu, or 8.7 percent of the cultivated land. An additional 7.4 percent lies in raised paths through fields. The area farmed by peasants themselves averages 0.18 mu. Nevertheless, it is still not used to the full. Output value from land that peasants farm themselves amounts to only 20 percent of the output value from sideline occupations, so continued improvement in all-round economic benefits holds great potential that can be tapped. Additionally, the breeding of poultry and small livestock has vast prospects, and development of handicraft products is also worthwhile.

The development of peasant household sideline occupations requires centralized planning and strengthening of state plan guidance. Family sideline occupations may be principally in a single industry or economically diversified for all-round development. The departments concerned should promptly provide fine breeds of livestock and poultry, organize epidemic disease-prevention services, institute scientific management, and link production and marketing through the signing of agreements, relating them to state plans for healthy development.

In the Shortrun, Where Should Attention Be Directed for Development of Agricultural Sicence and Technology?

Practice has shown that development of agricultural science and technology is related to the large problem of improvement in the agricultural labor productivity rate and to the lowering of production costs, and is the key to peasants becoming prosperous with all possible speed. In order to meet Western Sichuan Plain development needs, in the short run it is necessary to devote attention to work in several quarters, focus on requirements for rice, wheat, oil, and other economic crops as well as the raising of livestock and poultry, emphasize the breeding of fine varieties and experimental research on techniques for growing and raising them, while at the same time studying techniques for processing and using agricultural and sideline products; increasing varieties, sizes, colors and designs; improving quality; and expanding markets.

There must be intensification of technical promotion work, with emphasis on the three "transfers." First, following introduction and experimentation, the fruits of scientific techniques from elsewhere must be transferred to the local area. Second, demonstrations and experiments must be used to transfer to production the fruits of research of local scientific research units. Third, there must be summarization and improvement to transfer the traditional techniques used by peasants rich in experience to the broad masses of peasants. An effective means of technical promotion is to institute technical promotion responsibility systems, encouraging compensation for services, and gradually developing in the direction of specialization and socialization.

Technical training should be intensified, with vigorous efforts exerted in the development of rural intellectual resources. Statistics from a survey conducted in Wenjiang Prefecture show that peasants in the prefecture possessing various kinds of technical skills numbered more than 160,000, or 3.5 percent of the rural population. When those in the rural villages of Chengdu, Jinyang, and Leshan are added in, there are an estimated 300,000 or more. Investigation and research during the past few years has shown that few of them are used. In the shortrun it is necessary to organize technical training, the emphasis going first to nurturing and improving a group of technical mainstay cadres and using them to stimulate the peasants to study and use scientific techniques to give impetus to the development of agricultural production.

IMPROVEMENT OF BREEDS OF OXEN REPORTED

Chengdu SICHUAN RIBAO in Chinese 1 Jul 82 p 2

[Article: "Daxian Prefecture Obtains Heartening Results From Fine Breed Oxen; Last Year 23,000 Head of Fine Breed Oxen Were Bred, 10.5 Times the 1978 Number"]

[Text] Dixian Prefecture's work with improved breeds of oxen has won heartening success. Last year the prefecture raised 903,000 head of oxen, an increase of 41,000 over 1978. Fine breed oxen bred numbered 23,000, or 10.5 times the 1978 number, and accounted for 22 percent of the province's 105,000 head. Uncontrolled crossing and random breeding has been stopped, and the poor composition of cattle herds has been improved to a very large extent.

Dashan Prefecture, located in the southern foothills of the Ba Mountains, has more than 14 million mu of grassy mountains and slopes suitable for raising livestock. It has historically been a famed ox producing region. However, constrained by tradition and custom, plus the effects of "leftism," the people took a narrow view of raising oxen for use as draft animals, which seriously impeded development of commodity production.

When the spring freshets of the Third Plenary Session of the 11th Party Central Committee wafted into Bashan, the Daxian Prefecture CCP Committee and government administrative office leaders emphasized emancipation of the mentality and set to rights the position of the livestock industry, placing on their daily agendas the conversion of "grass" into "meat" and improvement of breeds. In 1977, before the province set up pilot projects for superior ox breeds, because Tongjiang County's local breeds of oxen were of inferior quality and did not sell well either in foreign trade or domestically, the County CCP Committee instructed livestock stations and the Foreign Trade Bureau to quickly give attention to improvement of breeds. Leading comrades in these two units went to Beijing where they bought and brought home with them slightly more than 300 doses of superior breed forzen semen. They bred 14 head, four of which became pregnant, all of the calves produced surviving. This was the first time that success had been achieved in improving the province's breed of oxen.

Subsequently, the national Ministry of Agriculture named seven commodity ox base counties in Dzxian Prefecture. The province selected five counties in Daxian Prefecture that had run breed improvement pilot projects. Over the years breed improvement tasks had increased and difficulties had increased with them. Some commune members did not believe that frozen semen could be used for breeding, and when those raising animals brought them to be bred, as soon as they saw it was to be artificial insemination, they quickly led them back home. Technical requirements for frozen semen breeding are very strict, but at that time technical capabilities were weak. Moreover, the frozen semen had to be brought from Chengdu, and the liquid notrogen had to be brought from the bull station of the import farm in Chongqing. Once the railways department mistakenly thought that the liquid notrogen container was dangerous goods of which transportation was prohibited, and an incident occurred in whih the shipper was detained. In the face of these difficulties, under the guidance of CCP Committee and government leaders, employees on the livestock frontline conscientiously and earnestly developed the work of improving ox breeds. Xuanhan County used written materials, photographs and drawings, and lives displays on a 17-commune circuit over a 4-month period, and it is estimated that these were seen by more than 80,000 persons. Pingchang County organized forces to compile more than 4,500 copies of materials, and used wired transmissions and propaganda to educate the masses. During the past several years, the prefecture has secured 985,000 yuan of local public finances and has taken 7 million jin of grain from reserves to launch a livestock raising industry. Since 1979 it has trained a total of 262 insemination personnel and has run technical training classes 33 times. Seven foreign breeds have been introduced to the prefecture, including Simmental, Charolais, Hereford, Angus, Limousin, Shorthorn, and Moleihui [1075 4959 3500]. Forzen semen has been used to breed more than 68,000 cows in order to produce more than 37,000 hybrids, which account for 32 percent of the province's total number of hybrid oxen. In 1980, Bazhong and Xuanhan entered the ranks of the country's 25 advanced counties for fine breeds, and in April last year, the Ministry of Agriculture convened a national livestock work conference in Bazhong County, which was yet another boost for Daxian Prefecture's fine breed oxen work. Since the lunar new year, workers on the frontline of the livestock industry in Daxian Prefecture have exerted greater efforts to carry out technical training early, to prepare materials early, and to begin breeding oxen early, giving further impetus to the work of improving breeds of oxen.

NEED TO MAINTAIN STRUGGLE AGAINST DISASTERS STRESSED

Kunming YUNNAN RIBAO in Chinese 25 Jun 92 p 1

[Article by commentator: "A Look at the Province as a Whole in Light of Qujing Shows Need For No Slackening in the Attitude of Struggle Against Disasters"]

[Text] This spring Qujing Prefecture was stricken by one disaster after another, including the return of cold in the spring, hailstones, floods, and waterlogging, and some counties also endured long drought. As a result, the early spring harvest of crops sown in late autumn was reduced, and crops sown in spring for fall harvest were seriously affected. However, thanks to the clear-cut attitude of struggle against disasters on the part of all levels of CCP committees and government, the prompt and vigorous actions taken, the proper direction given, and the stability of mass thinking, production proceeded in an orderly way in the face of disasters, and fairly good results were gained. The early spring harvest was painstakingly gathered and threshed, losses being less than had been originally anticipated, and oil-bearing crops achieved substantially increased output. Although rice transplanting got underway late, it proceeded fairly quickly. By about 21 May, more than 1 million mu had been transplanted and rice producing counties had fulfilled between 80 and 90 percent of their transplanting tasks.

A look at the province as a whole in light of Qujing shows that we cannot slacken for a minute our attitude of struggle against disaster in order to achieve bumper harvests. This year's crop to be harvested in early spring started off very well in Qujing Prefecture and a bumper harvest was in sight. Then disaster suddenly struck. Some grassroots level cadres looked at the fields and cried bitterly, not knowing what to do. However, prefecture and county CCP committee leaders kept clear heads. They realized that reduced yields from the early spring harvest were bad, but by no means frightening. What was to be feared was a wavering of confidence in being able to resist disaster and go on to achieve a bumper harvest. They unified thinking from top to bottom, analyzed the disaster situation, sought favorable conditions in an unfavorable situation, and constructed a solid mental defense line in the face of disaster. This defense line was shown to be very important. With this defense line, we could be one with the masses and find various means of countering the disaster. Without this defense line, we would have been at a loss about what to do ro have been weak and powerless or even disheartened, and we would have lost the battle against natural disasters.

If victory was to be won against disaster, in addition to confidence there would have to be some reliable measures to provide assurance. Experience in other prefectures of the province, and the present practice in Qujing Prefecture both demonstrated that a healthy production responsibility system is a most effective measure for mobilizing the masses to join in the struggle against disaster. The masses in Huangnihe Commune in Fuyuan County gleaned 60,000 jin of wheat from fields that had been battered to the ground by hailstones. On the evening of the very day on which the hailstones fell, Banqiao Commune in Luliang County began soaking more seed grain, and cleared away the ice water on the following day. In Yilang County, the masses took rugs and bedsheets from their homes to protect the seedlings from frost and worked all night long. Let me ask: Could this have been done when everyone "ate out of a large common pot? The Qujing CCP Committee believe that the large numbers of cadres who went into the countryside this year to help perfect the production responsibility systems had a very great bearing on the ability to make big achievements in the current struggle against disaster, and this is a very sensible view.

Disasters inevitably create losses, and this was a fact that had to be faced. But simply shouting the slogan, "no reduction in outout in a year of major disasters" is of no help at all in making up for or reducing losses. The method Qujing Prefecture used was as follows. They obtained grain through the use of scientific techniques. When the small seedlings were frozen, they enlarged the area in which seedlings were grown under plastic sheeting to more than 5,300 mu. When the early spring harvest sustained losses, they hastened promotion of advanced techniques for the fall harvest. This year the directional planting of rice in rows showed a more than twofold increase over last year, and both the area of spread of fine rice varieties and hybrid corn doubled. The masses said that this year's disasters were a rarity and the quality of planting was also a rarity.

After the disasters, the difficulties of hardship households were more pronounced, and the job of helping the poor became more urgent. In addition to issuing relief supplies and loans at once to seriously stricken production teams (or households), Qujing Prefecture arranged for party members and cadres to assume sole responsibility, and together with production teams they went to help hardship households. They were not permitted to eat or drink in hardship households, and most problems of the households enjoying the five guarantees [childless and infirm old persons who are guaranteed food, clothing, medical care, housing and burial expenses by the people's commune], of the four dependents [families of martyrs, servicemen, and others], as well as those of hardship households were fairly quickly solved. This not only gave impetus to the struggle against disaster to produce, but also demonstrated the superiority of the socialist system.

Natural disasters usually strike without warning, and their consequences are hard to eliminate in a short period. Consequently, when taking action to resist disasters, one cannot be concerned only about the present, but one must take care of many things at the same time and make all-round arrangements. Now Qujing Prefecture has laid plans for expanding the planting of the "four fields" (alternately cultivated and fallow land, the two wastelands, orchards, and empty land in mulberry groves), the "single field" (seedling field), and the "two ridges" (ridges between fields and long ditches), as well as an increase in the late autumn crop area. This thinking has been well worked out and can provide food for thought for others.

A look at the province as a whole in light of Qujing shows that when early resistance measures are taken against disasters that have occurred, and early prevention measures are taken against disasters that have not yet occurred, prospects for success in achieving a bumper harvest for the year are hopeful.

TITLE: "Report on the Rapid Control and Eradication of Enzootic Pneumonia in Swine"

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] in Chinese No 5, May 82 pp 8-11

ABSTRACT: For a long time, swine pneumonia [swine asthma] has been a serious threat to the development of the hog industry and there have been large economic losses. In 1964, the author proposed a simple method of diagnosis without the aid of drugs or x-ray but as it was found to be unsuitable for young piglets, etc. it was never adopted. The author again attempted to use x-ray to diagnose all the swine in the country for thorough treatment of the diagnosed cases with terramycin to control or even eradicate the disease within as short a period as 3-4 weeks. This technique was experimented in 1961, 1964, and 1976. The experimental procedure and result of the 3 experiments, in farms of a swine population of 63, 95, and 811 pigs respectively, are reported in separate chapters in the paper. The technique relies on x-ray alone for diagnosis without resorting to the tedious method of surgically removing unborn fetus or selecting piglets from healthy or naturally cured sows only in an attempt of gradually raising a herd free of this disease. The treatment consists of terramycin only, in various doses and modes of administration.

TITLE: "A Survey of 'Panting Disease' in Cattle"

SOURCE: Beijing ZHONGGUO SHOUYI ZAZHI [CHINESE JOURNAL OF VETERINARY MEDICINE] No 5, May 82 pp 11-13

ABSTRACT: In recent years incidences of a "panting disease" have been occurring among cattles of some areas of Guangdong, Guangxi, Hunan, etc. provinces (regions,) chiefly among water buffalos, with some cases among yellow oxen and dairy cows. The symptoms are fever, asthma, cough, running nose, and edema. Dissections revealed pulmonary edema or emphysema, chest and abdominal fluid accumulation, and inflammation of the nasal septum. For the purpose of determining the pathogen of this new infectious disease, a survey was carried out, along with a large quantity of laboratory tests. Klebsiella pneumoniae were isolated from some diseased cattles; the findings are yet not sufficiently conclusive for a diagnosis. The survey data also indicate a close relationship between swine asthma (swine enzootic pneumonia) and this panting disease of cattle.

TITLE: "Effect of Trypsin on the Vernalization Process in Winter Wheat"

SOURCE: Beijing ZHIWU XUEBAO [ACTA BOTANICA SINICA] in Chinese No 3, May 82 pp 241-246

TEXT OF ENGLISH ABSTRACT: This paper deals with the experimental results of the effect of trypsin on the vernalization process in the winter wheat. The variations of both the trypsin-like enzyme activity and the soluble protein content during vernalization in winter wheat seedlings were assayed. The results are as follows: (1) When the vernalization was progressing to the middle stage (around 25 days) the seedlings of the winter wheat were moved into the room temperature for continuous culture. These seedlings possessed the ability to ear after this kind of treatment, but earing development was rather late. Whereas the development of the earing was much earlier by treating them with 100 ppm trypsin just after moving into the room temperature condition. (2) Earing could not be induced by treatment with trypsin (100 ppm) in nonvernalized winter wheat. (3) Vernalization process was promoted in the initial period by trypsin under the low temperature, but it was inhibited in the middle and there was no remarkable effect on the developmental

[continuation of ZHIWU XUEBAO No 3, 1982 pp 241-246]

process in the later period. (4) There was no effect by the treatment of trypsin on the spring wheat under the conditions with or without vernalization. (5) The trypsin-like enzyme activity during the cold condition was increased in the initial period, then decreased remarkably later, but at the same time the soluble protein content increased rapidly. These results indicate that at the middle-later period of the vernalization the synthesis of some specific proteins is very important for the proceeding of vernalization.

TITLE: "The Model of Relations of Rice Tillering to Light and Temperature Conditions"

SOURCE: Beijing ZHIWU XUEBAO [ACTA BOTANICA SINICA] in Chinese No 3, May 82 pp 247-251

TEXT OF ENGLISH ABSTRACT: A preliminary study was made for the model of the tillering growth and decline of the rice colonies, which was analytically estimated with the agro-climatic data of 1973-1979 in Shanghai suburbs. The estimating result approximates to the observed value. The model we describe is $y_x = a_o + (a_f - a_o)e^{\frac{-c(d_2-x)^2}{x^2}}$. Here y_x represents the total number of rice stems in unit area when the accumulated temperature is x, which is accumulated by the effective temperature above 10°C since the transplanting of the rice seedlings, a_o is the basic seedling number in unit area, a_f is the total stem number in tillering peak, and c and d are experiential coefficient which are calculated with experimental data. For the stem number of a single plant, the model is expressed by $Y_x^o = 1 + (a_f^o - 1)e^{\frac{-c(d_2-x)^2}{x^2}}$. The actual data were used to illustrate that the

[continuation of ZHIWU XUEBAO No 3, 1982 pp 247-251]

model mentioned above is applicable not only to both Japonica and Indica rice of all varieties, but also to the description of the regional mean tillering state. When a_f^0 is known, it can be calculated with its associated light and temperature conditions.

TITLE: "Increasing the Unit Yield is the Major Way of Further Development of China's Grain Production"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 19-21

ABSTRACT: The farmers usually say adding one chi in width is not as good as one cun in thickness to explain their view of the relationship between enlarging the acreage and increasing the unit yield. These words in fact explain in a nutshell the way to obtain a better economic benefit from agricultural production in China. In the past, some efforts were given to raise the unit yield of grain crops but in general there was not enough emphasis The major route was always to expand the cultivated acreage and to raise the ratio of grain crops in the existing acreage. The results were excessive land reclamation, the destruction of forests, the abandommentof animal husbandry, and the shrinking surface of lake waters. The efforts were twice as great as the gains while creating erosion, floods, salinization, desertification, and ecological imbalance. In view of consumption needs, in 1980 the per capita grain consumption for China's one billion population was 649 jin, 100 jin less than the world average of 800 jin. [? 150 jin less] If the level of consumption is to be raised to 2,400 Cal per person per day of the world average, raising the unit yield is obviously the only way. Ways of reaching this goal are detailed, using the yield of rice in Japan, corn in the USA, and wheat in Mexico as the examples.

TITLE: "Speed up Agricultural Development in Henan Province by Concentrated Attack on Medium and Low Yield Areas"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 21-23

ABSTRACT: At present, in the province as a whole, the grain yield is less than 600 jin/mu/year and there are 72 low yield counties where the distributed income per person is below 100 yuan [per year ?]. These counties are distributed mainly in Huanghe-Huaihe plains and the hilly and mountainous areas. The population of these areas amount to 62.2 percent of the provincial total, having 71 percent of the cultivated acreage and 60.5 percent of the total grain production. Only 43.3 percent of the fields of these areas are irrigated and the 51 jin/mu chemical fertilizer applied is 21 jin less than the provincial average. In a concise yet inclusive manner, this paper proposes possible ways of changing the medium yield to high yield, the low yield to medium yield in these areas very fast with minimal capital investment. Development of cash crops, afforestation, and diversification are included in the ways of improving the production of these areas.

TITLE: "Strengthen Planning and Guidance for Comprehensive Development of Farming, Industry, and Auxiliary Production"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 36-39

ABSTRACT: This paper attempts to answer the much debated question of the status of commune-brigade industry in the rural economy by an analysis of the condition in Tianjin City. The suburbs of Tianjin have a large population and few resources. The cultivated land per capita is only 1.96 mu, while the average of the vegetable farmers is only 0.325 mu/person. The production expenditure is high and the income is little. The net income per mu in 1980 was only 39.1 yuan for cropland and 158 yuan for vegetable-land. The attitude of preferring industry over farming and vegetable production exists, naturally. For 23 years, there has been a policy of controlling the price of vegetables while, at the same time, allowing the production cost to rise continuously. In the 8 years of 1973 to 1980, the cost of producing major fruits and vegetables has more than doubled but the sales price remains the same if not lower. Animal husbandry has not been developed at all. To use cucumber as an example, due to the high cost of plastic films, the economic benefit of raising it in tents was notmuch better to begin with and the windstorms in Apr and May 81 destroyed the tents, the spring and summer vegetables etc. to cause the vegetable farmers to lose 8 million yuan. It is small wonder that few would try the technique again. Under these conditions, the author believes that the income from commune industries must be included in the income distribution of agricultural production if the two are to develop harmoniously together.

TITLE: "A Survey of the Condition of Diversification in the 46 Production Brigades of Yueyang Prefecture"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 40-43

ABSTRACT: The authors visited 46 production brigades of 22 communes of the 4 counties of Huarong, Linxiang, Yueyang, and Xiangyin in the prefecture to find the way of guiding the farmers to prosperity quickly, now that the system of production responsibility has become the general practice in rural villages. In the 3 years the per capita income of 35 brigades has risen to 404 yuan, an increase of 135 percent over that of 1978; while that of 11 brigades has risen to 186 yuan, an increase of 70 percent only. The difference between the 2 groups is successful diversification. For the 11 brigades, diversification still is like "exchanging eggs for salt;" theirs is still largely a self-sufficient economy in the tradition of barter to make it very difficult for them to prosper. The paper devotes its second half to analysis of the experience of the 35 successful brigades and proposals for the 11 not-so-successful brigades.

TITLE: "Past and Future of Economic Solidarity Between State-operated Frams and Rural Commune-brigades"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 50-52

ABSTRACT: Since the widespread establishment of State-operated farms in China, conflicts with rural commune-brigades have continued to surface in various forms, largely with respect to wastelands, mountain forests, grasslands, and sources of water. The subject of solidarity arises in the process of searching for ways to resolve these conflicts. In what form the linkage of these two ownership systems should take remains an unresolved problem, however. Following the peak of communization in 1958, some land and people were incorporated into State farms. At that time, about 40 percent of the land and 50 percent of the people of the farms were of commune origin. These independent farmers, who were used to keeping the profit and bearing the loss, found themselves unable to adjust to the life of employees, however. According to statistics, by 1963, half of the newly incorporated had withdrawn taking 8 million mu of land with them. More communes withdrew during the turbulent years after 1966. A new form of loose connection started in the spring of 1979, usually involving joint enterprises in such products as fruits, tea, milk, poultry, etc. In some cases, a State farm is invited by a poor brigade to invest

[continuation of NONGYE JINGJI WENTI No 6, 1982 pp 50-52]

much needed capital to plant rubber trees, to purchase machinery, to provide technology for a certain reward or for proportional division of profit. At present, China has more than 2,000 State-operated farms as well as 2,000 county-level supply and sale associations that are large scale enterprises located near rural villages. They should be considered as a powerful force capable of helping the rural communes and brigades to develop the rural economy. Some ways of utilizing this force are suggested.

TITLE: "Beijing Regional Symposium Held by Chinese Agricultural Economics Society"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 6, 23 Jun 82 pp 53-56

ABSTRACT: A Beijing Regional Symposium was held by Chinese Agricultural Economics Society on 30 Mar to continue the discussion of the problem of development strategy of Chinese agriculture. More than 50 persons affiliated with agricultural colleges, research organizations, and operational departments in Beijing attended. This paper provides excerpts of speeches delivered by the following persons at the symposium: (1) LI Renfeng [2621 0088 1496] of the Institute of the USSR and Eastern Europe, Chinese Academy of Social Sciences; (2) ZHANG Tong [1728 2717] of the Former Bureau of Planning, Ministry of Agriculture; (3) YANG Jun [2799 0971] of Chinese Academy of Agricultural Sciences; (4) LI Shihui [2621 1102 1979] of Institute of Agricultural Economics, Chinese Academy of Agricultural Sciences. All are optimistic regarding the possibility of resolving the problem of food grain in China. With regard to strategic measures for bringing about such a resolution, the speeches do not contain any suggestion beyond the normal modernization, organic farming, unified national decision making, diversification, supporting commercial grain production, etc.

TITLE: "It is necessary to Raise the Benefits of Existing Water Conservancy Facilities of Agricultural Fields"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 7, 23 Jul 82 pp 11-13

ABSTRACT: Since the liberation, a large number of water conservancy structures have been built in Kaifeng Prefecture and they have had some definite function in the development of agricultural production. Due to the fact that the theory of expanding reproduction of Marxism was not understood, these new structures were viewed as expanded reproduction so that they were not well maintained, repaired and utilized. Under the influence of leftism, those who wanted to expand the reproduction action of existing structures were considered as conservative, negative, and do-nothing types because the leftists believed that adding new engineering structures there is an expanding of reproduction. According to the year-end statistics of 1980, the design capabilities of the existing water conservancy facilities of the prefecture are to benefit 6 million mu but only 2.70 million mu benefitted. The prefecture has 50 thousand wells and 2,000 mechanical and electrical irrigation stations. Not much capital investment is needed to add or lengthen some channels, level a piece or two of the fields, etc., to enlarge the irrigation benefit to some additional 2-3 million mu of fields. Strengthening management and implementing the system of responsibility are all that are needed to accomplish this goal. Detailed measures to carry out this idea are proposed.

TITLE: "Inquiry Into the Problem of Rural Energy Sources in Fujian Province"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 7, 23 Jul 82 pp 44-46

ABSTRACT: Since ancient times, firewood and stubbles have always been the fuel of rural villages in Fujian. It was the traditional fuel for cooking, rural auxiliary industries, etc. A few places in the province, there were some small coal pits mined with native methods but inconvenience of transportation cause coal to be unimportant as a rural energy source, the same may be said for hydroelectrical, wind, electrical, and petroleum power. After the liberation, the development of production has greatly increased the consumption of energy, but the source of fuel remains essentially the same. The paper analyzes the supply potential of solar, hydroelectric, biological, forest tree, marsh gas, wind, geothermal, and sea water energy in the province. Ways of conserving energy are also briefly suggested.

TITLE: "The Influence of Shelterbelts on the Temperature of Wheat Leaves"

SOURCE: Beijing LINYE KEXUE [SCIENTIA SILVAE SINICAE] in Chinese No 2, May 82 pp 135-142

TEXT OF ENGLISH ABSTRACT: The temperature of wheat leaves on growing plants in experiment blocks in and out of a shelterbelt system was measured by the infra-red thermometer. Data showed the following results: (1) Shelterbelt appeared to have a cooling effect on the leaves of the plants in the system in a dry season or in drought areas. (2) A change of the air current strength was made to induce a corresponding variation of eco-environmental factors which caused a difference in the leaf temperature of wheat plants in and out of a shelterbelt. (3) After the strength of the hot, dry air current reached a certain level, the different value between the front and the back of a shelterbelt had a tendency to decrease. (4) The mean temperature on leaves of the wheat plants behind the shelterbelt was 1.3°C which was lower than that of those in the open field, during the period of jointing stage to maturity. Their accumulated temperature was 49.5°C less, which was about the equivalent of 2 days of temperature accumulation. The date of maturity of those wheat plants behind the shelterbelt was delayed about 2-3 days.

TITLE: "A Study on the Rationality of Application of Modern Mobile Logging Machinery in China"

SOURCE: Beijing LINYE KEXUE [SCIENTIA SILVAE SINICAE] in Chinese No 2, May 82 pp 185-191

TEXT OF ENGLISH ABSTRACT: In the last decades, countries that are advanced in forest industries have developed various mobile logging machines (feller-buncher, harvester, processor) for the purpose of realizing full mechanization. This paper gives a brief account of such sophisticated mobile logging machinery. China has imported some such heavy logging machinery from overseas, which are being tested at present. First results indicate that this heavy machinery is not suitable for the present stage of development in China. From the socioeconomic point of view, for the moment, it is not desirable to introduce such expensive and sophisticated machines, due to the abundant availability of manpower resources at extremely low cost. We should give priority to appropriate technology which requires less investment and brings more benefits.

TITLE: "Comparison of Some Properties of Two Groups of Phage of Xanthomonas Oryzae Dowson"

SOURCE: Tianjin ZHIWU BINGLI XUEBAO [ACTA PHYTOPATHOLOGICA SINICA] in Chinese No 2, Jun 82 pp 1-6

TEXT OF ENGLISH ABSTRACT: More than 20 isolates of the bacteriophage of Xanthomonas oryzae from leaves and seeds of diseased rice plants and irrigation water of diseased paddy fields were separated into 2 groups on basis of their morphology and other properties. Phages of group XOP 1 (represented by isolate OP-3) produce large plaque about 3 mm in diameter. It is tadpole shaped with a polyhedral head of 65 nm in diameter, and a striated non-contractile tail of 140 x 18 nm in size. The latent period and raising period are respectively 40 and 30 minutes, and their average burst size is about 35 plaque forming units (PFU) per cell. Phages of group XOP 1 are completely inactivated by heat treatment at 58°C for 10 minutes and

[continuation of ZHIWU BINGLI XUEBAO No 2, 1982 pp 1-6]

the unabsorbed free phages of this group are inactivated by ferric salts solution (10^{-4}M.) Phages of group XOP 2, represented by isolate OP-12, produce small plaque about 1 mm in diameter. It is also tadpole shaped, with polyhedral head of 70 nm in diameter, and a short contractile tail 90 x 20 nm in size. The latent period and raising period are 80 and 50 minutes respectively and their average burst size is about 8 plaque forming units per cell. Phages of group XOP 2 are completely inactivated by heat treatment at 68°C for 10 minutes. Serologically they are also different, experimented phages of group XOP 1 and XOP 2 are specific to Xanthomonas oryzae, but phages of group 2 is much broader in spectrum of its hosts than group XOP 1, judging from their reaction to different isolates of Xanthomonas oryzae.

TITLE: "Varietal Resistance of Wheat to Powdery Mildew"

SOURCE: Tianjin ZHIWU BINGLI XUEBAO [ACTA PHYTOPATHOLOGICA SINICA] in Chinese No 2, Jun 82 pp 7-14

TEXT OF ENGLISH ABSTRACT: Seedlings of wheat species and varieties resistant or susceptible to powdery mildew were inoculated with conidia of Erysiphe graminis tritici. About 60 percent of the conidia germinated and formed appressoria within 8 hours after inoculation. The percentage and rate of conidia germination on the leaf surface of resistant and susceptible wheat varieties showed no difference at the early stage of infection. The difference became apparent at the stages of penetration and further development. Earliest penetration was observed on the highly susceptible group 12 hours after inoculation, 83 percent of germinated conidia to penetrate within 36 hours. Less germinated E. graminis tritici conidia penetrated into leaves of resistant varieties of wheat than into those of susceptible ones. During 36 hours, the percentage of penetration of the susceptible, resistant, and highly resistant varieties were 65, 45, 27 percent respectively. The haustorial formation in the case of resistant varieties delayed and the haustoria developed in the epidermal cell of resistant varieties were smaller. On resistant plants developed fewer, less dense colonies with less sporulation than on the susceptible plants.

TITLE: "Two New Forms of Fusarium avenaceum (Fr.) Sacc.: The Pathogens of Broadbean Stem-end Rot"

SOURCE: Tianjin ZHIWU BINGLI XUEBAO [ACTA PHYTOPATHOLOGICA SINICA] in Chinese No 2, Jun 82 pp 25-32

TEXT OF ENGLISH ABSTRACT: In our collection of Fusarium specimens, we obtained 2 isolates designated No Y088 and No Y089 of Fusarium avenaceum (Fr.) Sacc. from stem-end rot samples of broadbean plants from suburb of Kunming in Feb 1975. Cultural studies on PSA and PDA showed that No Y088 produced well developed mycelia and 2 types of macroconidia. One is the general avenaceum type, the other is the Graminearum type. No 089 produced merely pionnotes over the media and was characterized as a typical pionnotes type, although it may occasionally develop poor aerial mycelia on surface of the colony. Host range studies confirmed that both Y088 and Y089 infected broadbean and green pea and slightly infected Vicia cracca L in artificial inoculation, but they are much weaker in virulence than No Y086. The

[continuation of ZHIWU BINGLI XUEBAO No 2, 1982 pp 25-32]

growth rate of single spore colonies and the amount of sporulation of these isolates were compared. Based on the studies, the two isolates can be recognized as two distinct forms of Fusarium avenaceum (Fr.) Sacc.: namely Fusarium avenaceum (Fr.) Sacc.f. fabarum Ruan et al. f. nov. for Y088 and Fusarium avenaceum (Fr.) Sacc. f. fabalis Ruan et al. f. nov. for Y089.

SOURCE: Tianjin ZHIWU BINGLI XUEBAO [ACTA PHYTOPATHOLOGICA SINICA] in Chinese No 2, Jun 82 pp 33-40

TEXT OF ENGLISH ABSTRACT: The maize head smut disease (Sphacelotheca reiliana (Kuhn) Clint.) infected maize budlets and young roots of seedlings, but the percentage of infected budlets was higher than that of young roots. No significant difference of infection was shown in budlet sheath and hypocotyl. Infections occurred since the germination of seeds up to the 7-leaf stage and no infections took place after the 9-leaf stage. More seedlings were infected in the 3-leaf stage. Infection of the fungus was effected within the range of soil temperatures 3-35°C; the optimum was at 16-25°C (22°C.) No significant difference was observed in the percentage of infection of different sowing dates in spring. Maize plants sown in summer were rarely infected. Percentage of infection was high when the moisture capacity of soil was at 15.5 percent while decreased when the humidity was too high or too low. Seedlings emerged from a thicker layer of infected soil resulted in a higher percentage of infection. The fungus was observed to be able to live for 2 seasons under field conditions.

TITLE: "Tap Local Potentials and Speed up Construction in Mountainous Areas"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCE] in Chinese No 7, 1982, pp 2-5

ABSTRACT: In his position of county party secretary, the author made a resource inventory of his county covering 1760 square kilometers, between 628 and 1792 meters of elevation at one end of the Taihang Mountain range. Here winters are long and summers are not markedly different in onset, when most precipitation drops off, supporting one crop harvest per year. In this climate, potatoes grow better than wheat. To suit the terrain, fruit (apple, walnut and hawthorn) and mulberry trees are projected to be increased in area in addition to afforestation. The hydroelectric potential can power the opening up of local deposits of coal, marble and sulfur as well as the operation of small cement enterprises. Though reported with an optimistic tone, the author-cadre implicitly concedes difficulties ahead by his shifting the emphasis to trees and mines from the present cultivation of some 70,000 acres of marginal farm land for the nearly one-quarter million inhabitants.

SCIENTIFIC COTTON FARMING DISCUSSED IN TERMS OF OLD PEASANT ADAGES

Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 4, 1982 pp 10-11

[Article by Wang Ruohai [3076 5387 3189] and Li Xiulan [2621 4423 5695]: "Sowing of Seeds To Keep a Good Stand of Seedlings, Keys to Increased Cotton Yields (Scientific Truth in Old Peasant Adages")]

[Text] Sowing of seeds to keep a good stand of seedlings is the beginning of cotton growth and the beginning of field care. Only when seeds are sown well to maintain a good stand of seedlings can all other farming techniques be effective and a bumper harvest won. Consequently, sowing of seeds to maintain a good stand of seedlings is the most important key to increased cotton yields.

In the course of a long period of production, the broad masses of cotton-growing peasants in China have accumulated abundant experience in the sowing of seeds to maintain a full stand of seedlings. An old peasant saying goes:

> "When there are seedlings, growth can occur;
> "Without seedlings, one can only dream.
> "A full stand of seedlings makes for 30 percent of the harvest.
> "Sturdy seedlings make for half of the ripe cotton."

Cotton is a dicotyledenous plant whose seeds are large and its two cotyledons are fleshy, which makes it much more difficult for them than for other crops to sprout and emerge from the soil. The masses say that cotton has a large head and a thin neck, and when it pushes up against the soil, a lot of effort is required, and it is hard for it to come through the soil. Moreover, after sprouting, the young seedlings are tender and are easily affected or killed by diseases and insect pests. So, the broad masses of cotton-growing peasants urgently hope to get through the dangerous stage of sowing to get a good stand of seedlings without a hitch by first getting a full stand of seedlings, and then going on to getting early, sturdy, full, and even growth of seedlings.

How does one sow seeds to get a good stand of seedlings?

First, both the seeds and the soil have to be made ready before sowing. This forms a foundation for sowing the seeds to get a good stand of seedlings.

In preparing the soil, since the cotton growing areas of north China are usually dry in the spring with little rainfall, preparing the soil to preserve soil moisture before sowing is done is extremely important. An old peasant saying goes:

> "It takes deep plowing and fine harrowing to make the cotton grow; shallow plowing and coarse harrowing is a waste of effort.
>
> "When harrowing is done early, soil moisture is kept."

When cottonfields are plowed deeply in autumn and the surface layer is friable, not only is the breakdown of nutrients promoted and the fertility of the soil increased, but it also helps the soil accept more winter and spring rains or snows and irrigation water, making the basic soil moisture of the cottonfields good. In early spring right after the soil's surface thaws, or else following spring watering, harrowing should be done promptly to make the surface soil of the cottonfields friable and the underlying layer firm to reduce evaporation of the soil's water content and to preserve soil moisture, all of which helps sprouting of the cotton.

However, in south China cotton-growing areas where spring rains are fairly plentiful, it is necessary to dig trenches and erect ridges in fields to prevent water stagnation so that seedlings will be able to emerge. Therefore, their experience is: "When trenches are deep and ridges narrow, cotton will be harvested year after year."

As far as readying the seeds is concerned, seeds should be selected before sowing, largely by grain-by-grain selection, selection through the water flotation method, or through winnerering to get healthy, plump seeds. This is very important in improving cottonseed quality and in winning a full stand of sturdy seedlings. As the old peasant adage goes:

> "Good seeds produce good seedlings; good seedlings form good bolls."

Before sowing, cotton seeds should be properly processed. If seeds are allowed to absorb water before sowing, sprouting will be promoted. In addition, disinfecting for diseases and insect pests to reduce damage from them can be done. Seeds may also be separated so they may be sown evenly. Thus, an old peasant adage goes:

> "Soaking cottonseeds in water and rubbing them with ashes
> "Makes them sprout and grow well;
> "When cotton seeds are mixed in mud;
> "They sprout fast and grow evenly."

Nowadays very great development has taken place in the processing of cottonseeds, as for example the use of a 55-60°C hot water bath treatment, which forces sprouting of the seeds. Or sulfuric acid may be used to remove the fuzz from the surface of cottonseeds. Another treatment is use of pentachloronitrobenzene as a germicide in which seeds are mixed to prevent disease. Or furan insecticide may be used to mix the seeds to prevent insect pests, etc. These treatments make for better stands of seedlings when seeds are sown.

Second is knowing when to sow the seeds and giving careful attention to seed sowing techniques to improve seed sowing quality. This is a major technique for good sowing of seeds to insure good stands of seedlings.

Sowing of cottonseeds at the right time has a very important bearing on winning full stands and harvesting a bumper crop. If sown too early when temperatures tend to be low, a long time will be required for sprouting and many nutrients will be wasted. Cotton seedlings will have little vitality and be prone to damage from disease. Stands will be "early but not full." Conversely, if sown too late, though temperatures are high and seedlings sprout fast, stands will be "full but not early," which will be bad for increased cotton yields.

The cotton-growing regions of China cover a wide area from south to north. A look at some old peasant adages shows the best times for sowing cotton in local areas as derived from practical experience, as follows:

> "When the date trees bud, cotton should be planted." (North China).
>
> "When Qingming comes early and Lixia is late, the time of the grain rains [around 20 April] is right for planting cotton." (North China).
>
> "Before the grain rains is the right time for planting cotton; and after the grain rains is the right time for planting beans." (Hebei).
>
> "Before Qingming (around 5 April) is the right time for planting cotton. (Rangyang, Hubei).
>
> "When lotus leaves are as large as a copper cash, cotton is being planted everywhere." (Jiangxi).
>
> "When plowing for millet begins and plowing for flax is finished, following the grain rains is the right time to plant cotton." (Liaoning).

In deciding the time to plant cotton, temperature is most important. This is because when cotton sprouts, complex material changes take place within the seeds. If the temperature is right, these material changes occur rapidly, and the cotton sprouts and puts forth seedlings rapidly. Results of scientific experiments and practice in production during recent years show that the right time for sowing cotton is when ground temperature to a depth of 5 centimeters is stable at 14 to 15°C. In an overwhelming majoring of China's cotton-growing regions, the right time for sowing cotton is from mid to late April. In Chang Jiang basin cotton-growing regions of the south, it may be planted somewhat earlier than this, and in the North, in places such as Liaoning Province, it may be delayed somewhat.

For cotton to sprout, in addition to temperature conditions, it is necessary to consider moisture and air conditions as well. So the specific time when cotton is to be sown in various areas has to be flexibly understood in terms of diverse factors. As an old peasant adage has it:

> "When the moisture is there, don't wait for the time;
> "When the time has come, don't wait for the moisture."

This means that in cotton-growing regions of north China, sowing has to be done promptly when soil moisture conditions are right. If soil moisture conditions are right several days before the right time, sowing should be done right away without sitting around to wait for the right time. If soil moisture conditions are not good, but the time for sowing has arrived, ways will have to be found to combat drought and begin planting. One cannot wait until it rains and there is soil moisture to begin sowing. In south China's cotton-growing regions, the experience is as follows:

> "It is better to sow on a clear day than to sow on a wet day."

Inasmuch as there is much rainfall during the spring in southern cotton-growing areas, frequently the soil contains too much water and ventilation is poor, making the seeds prone to rot. Therefore, their experience tells them that seeds should be sown when the weather is clear; following rains when the soil is wet, it would be better to wait, etc.

> "On alkaline soils, which are cold, cotton should be sown around "beginning of summer" [around 5 May].

Saline-alkaline soils warm up fairly slowly, so cotton sowing has to be delayed by about 10 to 15 days later than normal. Only when sown around the time of "beginning of summer" will conditions be right for a full stand.

When sowing, care must be taken with proper sowing techniques to improve sowing quality. Depth of sowing must be right. If sown too deeply at low temperatures when there is little air in the soil, seedlings will have a hard time pushing up through the soil and will emerge poorly. If sown too shallowly, the soil surface will easily dry out and the cotton seeds will find it hard to absorb water, so budding and seedling growth will be hurt. Thus, an old peasant adage says:

> "If planted deep, seeds mold; if planted shallow, they dry out."

> "One finger deep is too shallow; two fingers deep is too deep; three fingers is too much and the seeds will be suffocated."

Because the weather is often dry with much wind when cotton is sown in the cotton-growing regions of north China, seeds that have been sown shallowly are prone to dry out, so they should be sown somewhat deep. In sandy soils or soils in which surface moisture is poor, seeds should generally be sown to a depth of 4 to 5 centimeters. In clayey soils or soils with good surface moisture conditions, seeds should be sown to a depth of 3 to 4 centimeters. As an old peasant adage says:

> "1 cun is shallow and 2 cun is deep; neither shallow nor deep is 1½ cun;
>
> "Plant shallow when wet and deep when dry."

In southern cotton-growing areas where there is much spring rain making the soil rather sticky and heavy, if seeds are planted deep; there will not be enough air in the soil and they will be prone to rot, so a shallow ditch should be dug and seeds covered lightly with soil. Thus, an old peasant adage says:

> "Seedlings can grow out from under a cun of soil."
>
> "Shallowly sown seeds will produce harvests year after year, but deeply sown seeds will produce a bad harvest."

When the weather is dry and soil moisture inadequate, seeds must also be sown well to assure full stands. The broad masses of cotton-growing peasants in China have figured out many ways in which to fight drought to plant seeds.

> "Deep sowing with shallow covering for a full stand of seedlings."
>
> "One finger deep sowing (in dry soil), two fingers deep for rush sowing, and three fingers or more deep and borrowing soil moisture."

"Deep sowing and shallow covering" requires deep sowing so that the seeds come in contact with moist soil, but with light covering so that once the seeds have absorbed moisture, they will be able to sprout out of the soil quickly. "Borrowing soil moisture" means that after seeds have been sown in drought conditions, they should be covered with moist soil taken from close by to thicken the moist layer of soil, which helps in seed absorption of water and sprouting. The wet seed planting mound developed by cotton-growing peasants in Shandong Province is a good way to fight drought to plant cotton; it should be advocated. The specific way used is as follows: A shallow trench is dug (to a depth of 3 to 4 centimeters), and is filled to the top with water (to provide soil moisture). Then seeds are sown by hand a certain distance apart, and the soil is mounded over them (to a height of about 2 cun). After most of the cottonseeds have rooted, the mound is pushed over and the soil leveled.

Third is intensification of field care after sowing as a way to assure good sowing to maintain a full stand. Inasmuch as completion of the sowing of seeds does not mean that everything will then go along without a hitch, ways have to be found to hasten the emergence of the cotton seedlings from the soil and to prevent or reduce the number of diseased or dead seedlings, making every effort not only to get a full stand but to get early, strong, full, and even stands of seedlings. China's cotton growing peasants also have had a great amount of experience in techniques for maintaining stands after sowing, as follows:

> "If the cotton is wrapped in a sheath, it will never sprout."

By this is meant that should the soil be compacted by rain after the cottonseeds have been planted and the soil become hard as a sheath, it will be very hard for the seedlings to break through the soil, and extremely easy for rotting of buds to occur with no seedlings developing. Therefore, following rains, it is necessary to loosen the soil and break the hard surface at once.

> "Gentle hoeing of the cotton, and it will thrive year after year."

> "Deep hoeing to increase soil temperature and the cotton will not develop black root."

This means that cottonfields should be cultivated early and frequently to loosen the soil. When the soil contains a fairly large amount of moisture, it should be cultivated more deeply. In this way soil temperature can be increased, the ventilation of the soil improved, the breakdown of soil nutrients accelerated, and both weeds eliminated and diseases and insect pests reduced to promote growth of sturdy seedlings and to reduce the number of dead seedlings.

> "If seedlings are replaced when they are small, a harvest can be had, but if seedlings are not replaced, a season is lost."

Ways should be found to replace seedlings that are missing in cottonfields. Replacement of seedlings must be done early and swiftly. The earlier, the less the effect on yields. Early on, resowing can be done; later, seedlings can be transplanted. The seedling transplantation method created by Shanxi labor model, Wu Jichang [0702 0679 2490], whereby seedlings with two leaves are transplanted without any soil on their roots saves both work and water, and has a high survival rate. It is a good way to assure full stands in cottonfields where seedlings are replaced.

> "If seedlings press upon each other, no bolls will form;
> "Where seedlings are scant, leave more; where seedlings are dense, leave fewer; if neither scant nor dense, leave the big ones."

Once the seedlings have emerged, they should be thinned and singled at once so that "seedlings do not press against seedlings," in order to achieve sturdy, full, and even stands of seedlings. The principle underlying thinning and singling of seedlings is that where seedlings are scant, more should be allowed to remain; where seedlings are dense, fewer should be allowed to remain. Generally one should leave sturdy cotton seedlings at a certain distance from each other.

Accompanying the development of scientific techniques and with the support of agriculture by the plastic film industry, new developments have taken place during the past several years in techniques for sowing cotton to maintain full stands. One has been the use of plastic film to cover seedling beds and the transplanting of seedlings that have been propagated. Another is the covering of open fields with plastic film, with the cotton growing directly under the plastic mulch. These are good ways to obtain full, early, sturdy, complete, and even stands of seedlings, and ways in which to increase cotton output remarkably.

COMMODITY CATEGORIES, PROCUREMENT EXPLAINED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 4, 1982 p 45

[Article by Ge Quanlin [5514 3123 2651] and Zhang Xiaonmao [1728 4382 5399], Ministry of Commerce: "How Are Agricultural and Sideline Products To Be Classified and Their Unified, Assigned, and Negotiated Procurement Done?"]

[Text] The division of agricultural and sideline products into categories, I, II and III, and their unified procurement, assigned procurement, and negotiated procurement are the national management methods for agricultural and sideline products, and the procurement policies currently in effect. In view of the state of development of China's productivity and the degree of importance of various agricultural and sideline products to the national economy and the people's livelihood, in order to have planned control over agricultural and sideline products, to do unified planning with due consideration for all concerned, to arrange industrial production properly, and to meet the needs of the people's livelihood and export trade, the state has divided agricultural and sideline products into three categories for management purposes, and has instituted unified procurement, assignment procurement and negotiated procurement policies.

Grain, cotton, and edible oils, which are agricultural and sideline products of greatest importance to the national economy and the people's livelihood, are classed as category I products, and unified procurement and unified marketing of them is practiced. Flue-cured tobacco, hemps, tea, silkworm cocoons, livestock products, sugar, live hogs, fresh eggs, fruits, major medicinal herbs, major aquatic products, mosa bamboo, raw lacquer, and such industrial raw materials, export goods, and items needed in the daily life of the people that are agricultural and sideline products of relatively great importance to the national economy and the people's livelihood are classed in category II, and assigned procurement and marketing in accordance with plan is practiced in their case. All agricultural and sideline products not included in categories I and II are Category III products for which negotiated procurement and negotiated marketing is practiced. In the case of Category I and Category II agricultural and sideline products, the state makes unified plans, sets unified prices, and carries out unified distribution. All procurement, marketing, transfer, import, export, and storage quotas for Category I goods is under the centralized management of the State Council. Category II goods are under the authorized management of ministries and commissions so entrusted by the State Council. Some products in this category or some quotas are under the centralized management of the state council. The various plans set for Category I and II goods are a major aspect in strengthening of state centralization of the macro-economy, and all jurisdictions and departments must insure their implementation. Active fulfillment of unified procurement and assigned procurement quotas through sales to the state is a glorious duty for which peasants must exert themselves to the full. In order to coordinate the self-determination of production teams, the initiative of peasants, and state economic plans, under the principle of concurrent concern for the country, the collective, and individual interests, it is also necessary to give peasants the right of control over products, within certain limits, in order to stir their enthusiasm for production. Disposal of Category I and Category II products remaining following fulfillment of stipulated base procurement figures or agreement quotas is to be done according to different methods depending on specific circumstances for different varieties of goods. For certain major industrial raw materials in short supply, export goods, and means of agricultural and fishing industry production such as cotton, flue-cured tobacco, moso bamboo, gao bamboo [4643 4554], cowhide and some other livestock products, considering that the country's needs are fairly large and that sources of supply are as yet insufficient, regulations do not permit peasants to sell such goods freely in markets, but rather the state continues to purchase them. Where quantities of goods required for marketing internally or abroad are fairly large, tea being an example, the state will also continue purchases of a certain proportion in order to arrange for internal and external requirements, any remaining amounts being permitted to be sold in markets. Other category II products needed in the daily life of the people are to be handled by the peasants themselves. They may be sold in markets or they may be purchased by the state at negotiated prices and sold at negotiated prices. Purchase prices paid for products remaining following fulfillment of quotas are allowed to fluctuate within certain limitations in accordance with the market supply and demand situation. Category II products are managed locally, and in accordance with State Council programs and policies they are to be purchased and marketed well and briskly. For a small number of important varieties of Category III products, in order to insure special export needs and the needs of large cities, management methods used for Category III products may be applied in order to control a certain source of supply. Specific varieties and methods to be used are to be decided by provincial, municipal, and autonomous region governments.

Many years practice has shown that the division of agricultural and sideline products into categories I, II, and III, and the institution of unified purchase, assigned purchase, and negotiated purchase as basic policies has been effective and in accordance with China's actual circumstances. It embodies the principle of taking the planned economy as the key link with market regulation playing a supplementary role, and plays a major role in promotion of production, in insuring needs, in stabilizing markets, and in stabilizing prices.

As the country's national economy readjusts, agricultural production develops, and agricultural and sideline products increase, specific policies and management methods for procurement of agricultural and sideline products must also conform to changes in production and marketing. Designation of specific varieties of goods as Category I, II or III will have to be properly readjusted on the basis of different circumstances for each variety.

Supplement: Current List of Category I and II Agricultural and Sideline Products

Category I: Grain, cotton, edible oils, and lumber.

Category II: Varieties of goods for which the Supply and Marketing Administration is responsible: Jute and ambari hemp, China grass, flue-cured tobacco, wool, sheepskins, xiao hu [1420 3275] sheepskin, kidskin, feathers, hog casings, pig bristles, mulberry silkworm cocoons, tussah silk cocoons, tea, fine quality sun-cured tobacco, grass mats, coir mats, bamboo, hao bamboo [4643 4554], citrus fruit, handmade paper, honey, raw lacquer, apples, tree fungus, star anise, kid leather, goat hair, sheep casings, red dates, hot pickled mustard tuber, day lily, rush mats, charcoal, draft animals, hemp, goat coasings. 2. Varieties of goods managed by the Ministry of Commerce: Live hogs, beef cattle, carcass-type sheep, fresh eggs. 3. Varieties of goods for which the Ministry of Forestry is responsible: Resin yuanjiao [0626 5231]. 4. Varieties of goods for which the Aquatic Products Administration is responsible: Large yellow croaker, small yellow croaker, hairtail, cuttlefish, butterfish, pomfret, conger pike, herring, slate cod croaker, flounder, prawns, abalone, sharkfins, fish maw, beche-de-mer, scallops, dried shrimp, small dried shrimp, squid, and jellyfish. 5. Varieties of goods for which the Ministry of Food is responsible: Tung oil, castor oil, wood oil, Chinese tallow tree oil, and catalpa oil. 6. Varieties of goods for which the Ministry of Foreign Trade is responsible: Peppermint oil and citronella oil. 7. Varieties of goods for which the State Pharmaceutical Administration is responsible (including Category II and costly medicinal materials): Musk, Pesoar, the rhizome of Chinese goldthread [Coptie chinensis], the bult of frittilary [Fritillaria thunbergii], licorice, Chinese wolfberry [Lycium chinense], Chinese yam, yuanhu [0337 3275], the bark of eucommia [Eucommia ulmoides], taro pulp, yinhua [6892 6363], safflower, ginseng (including yeshan ginseng), dangshen [codonopsis pilosula], Chinese angelica herb, chuanxiong [Coniososelinum unvittatum Turez], the dried rhizome of rehmannia [Rehmannia glutinosa], Atractylis ovata Thunb, peeled root of herbaceous peony [Paeonia albiflora], tuckahoe [Poris cocos], the tuber of dwarf lilyturf [Ophiopogon japonicus], monkshood, Aucklandia lappa, root of bidentate achyranthes [Achyranthes bidentata], root of Zhejiang figwort, root bark of the tree peony [Scrophularia ningpoensis Hemsl.], sanai-ginseng [Panax peseudo-ginseng], pilose antler tonic, root of membranous milk vetch [Astragalus membranaceous], chrysanthemum flower, bark of official magnolia officinalis], tuber of elevated gastrodia [Gastrodia elata], sharen [4263 0088] [Hedychium Coronarium], Chongcao [5722 5430], tiger bone pills, leopard bone pills, bear gall bladder, Quanchong [0356 5722, Chinese cassia, Aquilaria agallocha, Bufo vulgaris, Bacopa monniera, asses' glue, rhinoceros indicus, guangjiao [1684 6037], antelope's horn, frankincense, myrrh, dragon's blood [calamus craco], sandalwood, gongdingxiang [Jambosa caryophyllus], and xihonghua [6007 4767 5363]. 8. Varieties of goods for which the Ministry of Light Industry is responsible: sugarcane and sugarbeets.

FOOD, FERMENTATION INDUSTRIES CLASSIFICATION SYSTEM SUGGESTED

Beijing SHIPIN YU FAJIAO GONGYE [FOOD AND FERMENTATION INDUSTRIES] in Chinese No 2, 1982 pp 86-89

[Article by Qin Hanzhang [4440 0698 4545]: "Suggestions Concerning Classification of Food Industry in China With Appendix on Classification of Fermentation Industries (Classified Chiefly on Basis of Sources of Raw Materials)]

[Text] First, Agricultural Product Food Industries

(1) Grain Industry

For example:

1. Hull rice

2. Milled rice

3. Flour

4. Starch

5. Potato starch

6. Lotus root starch

7. Bread

8. Crackers

9. Maltose (Malt sugar), starch sugar (glucose), grape syrup (isomeric syrup)

10. Gluten, oleaginous buckwheat gluten

11. Sesame seed cakes

12. Oatmeal

13. Sliced tubers

14. Malt

15. Caramel

16. Pastries, cakes and sweetmeats

17. Pulse processing (soybean paste, soybean starch, beancurd, thin sheets of beancurd, (dried bean milk cream in tight rolls), dried beancurd, fried beancurd, pressed beancurd sheets, mung bean vermicelli, sheet jelly made from bean or sweet potato starch

18. Other (macaroni, puffed foods)

(2) Fats and Oils Industry

For example:

1. Pressed oils

2. Refined oils

3. Peanut butter, sesame paste

4. Margarine

5. Other

(3) Beverage crop processing

For example:

1. Tea industry (black tea, green tea, scented tea, brick tea, oolong tea)

2. Coffee roasting

3. Cocoa manufacture

4. Hops drying and smoking (beer hops)

5. Other

(4) Sugar crop processing

For example:

1. Sugar manufacturing industry (brown sugar, white sugar, granulated sugar, syrup, waste molasses)

2. Sugar refining industry (refined sugar, cube sugar)

3. Chocolate and gum manufacturing

4. Common candy manufacture

5. Other

(5) Condiment crop processing

For example:

1. Chili pepper processing (dried chilies, chili powder)

2. Fennel processing (fennel extract, fennel oil)

3. Clove processing (clove oil)

4. Fresh ginger processing (dried fresh ginger, fresh ginger extract, candied ginger)

5. Garlic processing (sugared garlic, salted garlic, pickled garlic, garlic heads, garlic powder)

6. Curry powder

7. Black pepper

8. Mustard, hot mustard sauce

9. Cassia bark, cinnamon powder, cinnamon oil

10. Nutmeg, mace

11. Other

(6) Medicinal crop processing

For example:

1. Peppermint processing

2. Ginseng processing

3. Chinese angelica processing

4. Eucalyptus extracting (cough syrup)

5. Other

(7) Tobacco crop processing

For example:

1. Cigarette industry

2. Water pipe tobacco
3. Plug tobacco
4. Shredded tobacco
5. Snuff
6. Cut tobacco
7. Cigar tobacco
8. Asthma tobacco
9. Other

Second, Orchard and Garden Product Food Industry

For example:

1. Fruit juice (including grape juice, fresh orange juice, lemon juice, etc.)
2. Syrup
3. Jelly, pectin
4. Marmalade
5. Jam
6. Dried fruit
7. Salted vegetables
8. Vegetables pickled in soy sauce
9. Pickled vegetables
10. Pickled Chinese cabbage
11. Dried vegetables
12. Preserved fruit
13. Dried flowers (lily buds, roses, daidaihua [7818 7818 5363], jasmine flowers, etc.)
14. Honeyed flowers (honeyed roses, honeyed sweet-scented osmanthus)
15. Other

Third, Livestock Products Food Industries

(1) Slaughterhouses

1. Livestock butchering
2. Livestock butchering

(2) Egg processing

1. Fresh eggs, frozen eggs
2. Egg powder (protein powder, egg yolk powder, whole egg powder)
3. Preserved eggs (1,000 year old eggs)
4. Salted eggs
5. Pickled eggs

(3) Meat processing

For example:

1. Frozen meat
2. Smoked meat
3. Salted meat, cured meat
4. Ham
5. Sausage, cured hog tripe
6. Air aged chicken, pressed duck
7. Lard, beef fat (including other animal fats and oils used as food)
8. Meat broth
9. Pork floss
10. Stewed chicken livers, stewed duck livers
11. Dried beef cooked with five spices powder
12. Other

(4) Dairy product processing

For example:

1. Milk (bottled milk, pasteurized milk, whole milk)
2. Butter
3. Butter fat (cream)
4. Ice cream and ice cream powder
5. Cheese
6. Condensed milk
7. Milk powder
8. Casein
9. Lactose
10. Whey powder
11. Sour milk
12. Kumiss (cow kumiss, horse kumiss, camel kumiss)
13. Skimmed milk
14. Other

Fourth, Forest Products Food Industry

For example:

1. Maple sugar
2. White pine syrup
3. Pine nuts
4. Chinese toon [Toona sinensis]
5. Mushrooms
6. Wood fungus
7. Bamboo shoots (dried slices of tender bamboo shoots, bamboo tips)
8. Other

Five, Aquatic Products Food Industry

(1) Breeding

(2) Catching

(3) Processing

For example:

1. Water shield
2. Water chestnut powder
3. Agar-agar (edible seaweed) (toufa cai [7333 4099 5475], laver, siliquose pelvetia)
4. Jellyfish
5. Kelp
6. Beche-de-mer
7. Fish oil, fish liver oil
8. Sharkfins
9. Whitebait
10. Frozen fish
11. Salted fish
12. Small dried shrimp
13. Lobster, shrimp (prawns)
14. Crabmeat
15. Scallops
16. Agar agar
17. Other

(4) Edible salt manufacturing (or salt making industry)

For example:

(1) Salt manufacturing

1. Sea salt
2. Well salt
3. Lake salt

(2) Salt refining

1. Refined salt
2. By-products

Sixth, Insect Products Food Industry

For example:

1. Honey
2. Beeswax
3. Royal jelly
4. Other (Silkworm chrysalis protein)

Seventh, Fermentation Industries (including distilling industries)

For example:

1. Soy sauce
2. Vinegar
3. Shaoxing wine (pressed wine)
4. Gaoliang liquor (distilled liquor)
5. Beer
6. Grape wines and other related fruit wines (pressed wines)
7. Apply wines
8. Foreign alcoholic beverages, sweet wines, and associated liqueurs (distilled liquors)
9. Sweet paste [3929 6830]
10. Lactic acid

11. Citric acid

12. Monosodium glutamate (MSG) and other amino acids

13. Enzymes (protease, amylase, isoamylase, stable isomerase, glucose oxidase, tannase, etc.)

14. Yeasts (pressed yeast, active dry yeast, brewers yeast, wine yeast, medicinal yeast, livestock feed yeast)

15. Alcohol industry

16. Other (Yeast for brewing wine or fermenting glutinous rice, fuqu [1133 2575], yeast for making hard liquor)

Eight, Food Storage Industry

For example:

1. Canned storage (canned goods)
2. Dry storage
3. Cold storage
4. Warehouse storage
5. Cellar storage
6. Pickling
7. Other

Ninth, Beverages and Cold Drinks Industry

For example:

1. Running water
2. Mineral water
3. Soda water
4. Other cold beverages (such as Coca Cola, malt or milk extract, sour plum concentrate, etc.)

Tenth, Vitamin Industry, Special Dietary Foods Industry

For example:

1. All kinds of eatable vitamins (multi-vitamin pills, single vitamin pills)

2. Baby foods
3. Old people's foods
4. Athlete's foods
5. Curative foods
6. Spaceflight foods
7. Convenience foods
8. Other

Appendix:

Problems of Specialized Composition of Fermentation Industry

The technical characteristics of the fermentation industry most readily reflect the level of modern scientific advance. For the mort part, they are chemical products and light industrial products obtained from fermentation carried out by micro-organisms.

The fermentation industry is best delineated in terms of the products of each industry.

Fermentation industry products may be generally divided into the following 10 categories:

1. Alcoholic beverages, alcohols, and solvents

Alcoholic beverages (including beer, yellow rice or millet wine, white spirits, cordials, wines, brandies, whiskeys, vodka, and various medicinal wines)

Ethanol (alcohol), butanol, acetone, glycerine, fusel oil.

2. Organic acids

Citric acid, lactic acid, acetic acid, tartaric acid (a by-product of wineries), fumaric acid, itaconic acid, gluconic acid.

3. Yeasts

Bread yeast, dietary yeast, medicinal yeast, livestock feed yeast

4. Amino acids

Monosodium glutamate (MSG), lysine, proteic acid, tryptophan, and other amino acids.

5. Antibiotics

Penicillin, aureomycin, streptomycin, neomycin, tetracycline, griseofulvin, bacitracin, tyrothricin.

6. Vitamins and growth hormones

L-ascorbic acid, cyano-cobalamin (vitamin B-12), riboflavin, biotin.

7. Enzymes

Takadiastase, amylase, protease, cellulose ester, pectinase, glucose oxidase, isomylase, stable isomerase, tannase, etc.

8. Polymers

Dextran (polydextran) and other polysaccharides

9. Fermented foods

Soy sauce, soy paste, beancurd milk, cheese, hot pickled mustard tuber [preserved Sichuan vegetable], pickled vegetables, etc.

10. Other

Diacetyl, dihydroxyacetone, anti-filtrable virus vaccine, ephedrine, ergotine, steroids, ribonucleotides.

PROVINCIAL NOTICE ISSUED ON 'THREE SUMMER JOBS'

Lanzhou GANSU RIBAO in Chinese 13 Jun 82 p 1

[Article: "Provincial People's Government Issues Notice Requiring All Jurisdictions to Base Themselves on Prevention of and Combat Against Calamaties To Do the 'Three Summer Jobs' of Production Well"]

[Text] On 10 June the provincial people's government issued a notice requiring all jurisdictions to base themselves on the prevention of and combat against calamities to do the "three summer jobs" [planting, harvesting, and field management] well.

The notice said that now that "grain in ear" [around 6 June] has passed, the busy season of the "three summer jobs" has progressed steadily from south to north throughout the province. Meteorology departments have forecast uneven distribution of rainfall throughout the province with the possibility of summer drought between July and September. Some places may suffer torrential rain or hailstone disasters, and mountain floods may be more numerous than in former years. All jurisdictions should base themselves on prevention of and combat against disasters to do a solid job of summer harvesting, summer planting, summer management and hot weather cultivation of the fields.

The provincial government has recommended that all activities in summer production center around the drought, waterlogging, hailstone, flood, crop disease and insect pest disasters that have already occurred or may occur. They should make multiple preparations and establish several lines of defense ideologically, organizationally, and materially to produce results link by link. Vigorous measures should be taken to defend against possible summer drought. Repair of ditches and the maintenance and repair of irrigation facilities and rural electric power lines should be taken firmly in hand, and fuel for machinery made ready so as to be able to combat drought when it occurs. Irrigation areas are to institute centralized management and handle matters strictly in accordance with regulations, make equitable use of water and conserve use of water so as to be able to irrigate more fields better. In addition to actively fighting against drought, conscientious work to protect against floods and high water also has to be done. Wheat, oil-bearing crops, and beans in summer fields should be harvested just as soon as they are ripe and hauled away as they are harvested to guard against fire, theft or molding in rainy and overcast weather, and to assure their safety. The masses are to be stimulated and organized to select and retain seeds. Places in which the sowing of summer crops did not fulfill plan, or places in which the harvest has not been good are to do everything possible, depending on local realities, to expand the area sown for the fall and multiple cropping plans. Where it is too late to sow grain, urgent action should be taken to plant vegetables, grass, green manure, planting them early, in large quantities, and well.

All out efforts are to be made in working and managing late ripening summer crops and fall crops, making sure than "until a bumper harvest is in hand, there will be no slackening of care." Account should be taken of the growth situation of different crops to inspect seedlings promptly and add seedlings where required, to hoe out weeds and loosen the earth, to provide topdressings of fertilizer, to irrigate at the right times, to control diseases and insect pests and such jobs as a means of upgrading the "three categories of seedlings," to prevent green drying and lodging of wheat, to increase the per thousand grain weight of wheat, and to improve quantity and quality of wheat. Opportunity should be seized to do a good job of summer plowing. "Summer plowing is like burning oil" has been a tradition in Gansu Province. Successful measures for combating drought to increase yields should be given attention everywhere, early preparations being made, and deep, careful, and much plowing done. Where conditions permit, floodwaters should be diverted to flow over the land.

The notice pointed out that responsibilities are great and time is short for doing the "three summer jobs." All levels of the people's government and all departments concerned, particularly leaders in prefectures and counties are to treat it as a central task that comes before all others in rural villages at the present time. Leaders are to go down into the frontlines to solve problems promptly. Commune and brigade cadres are to stand fast at their posts. Cadres and farm technicians are to be organized into work teams to give on the spot direction to peasants and to explain technical farming knowledge in terms of actual situations being faced. Commercial, supply and marketing, industrial and transportation, materials, and banking units are to actively organize the allocation and transportation of materials for the "three summer jobs," and to do a good job in the supply of chemical fertilizers, fuels, electric power for agricultural use, farm implements, and fine varieties, and the issuance of loans for agricultural use.

INCREASED PRODUCTION OF AQUATIC PRODUCTS STRESSED

Policy Measures

Guangzhou NANFANG RIBAO in Chinese 17 Jun 82 pp 1, 2

[Text] The Guangdong Provincial People's Government recently convened a provincial aquatic products breeding work conference at Foshan City to transmit and put into effect the spirit of the national freshwater fishing industry work conference, to summarize and exchange experiences in the province's aquatic products breeding work, and to study and enact policies and regulations on hastening freshwater breeding and the revival and development of marine breeding.

Guangdong Province CCP Committee member and director of the Provincial Agricultural Commission, Du Ruizhi [2629 3843 5347], presided over the conference and made a summarization. Guangdong Provincial Governor Liu Tianfu [0491 3944 1133] gave a speech at the conference.

Participants in the conference included deputy commissioners (or deputy mayors) of all prefectures (or municipalities) and comrades in charge at the Agricultural Office, the Aquatic Products Bureau, and the Hydroelectric Bureau, as well as deputy county heads (or deputy mayors) of each county (or municipality), and representatives of departments concerned under direct provincial jurisdiction. The conference was divided into two phases for discussion of freshwater breeding and marine breeding.

The conference agreed that since the Third Plenary Session of the 11th Party Central Committee, Guangdong Province has won remarkable achievements in aquatic products breeding work from diligent implementation of the CCP Central Committee's and the provincial government's "Decisions on Vigorous Development of the Aquatic Products Breeding Industry." In the course of 3 years the freshwater fishing industry has taken three giant strides. Between 1979 and 1981, it averaged an annual increase in production of more than 18,600 tons, an annual incremental increase of 8.8 percent. Within 3 years marine breeding area was increased by 53 percent and output rose fairly rapidly once again, increasing by 18 percent over 1979. However, current speed of development of the aquatic products breeding industry is still a long way from meeting the needs of the people's livelihood, and falls far short of the province's superior natural conditions. Continued efforts must be made. Acting on the basis of the annual freshwater fish output of 4 to 5 million tons, which is the target to be achieved by the end of the 1980's put forward by the CCP Central Committee, in combination with actualities in the province, the conference formulated a plan for the province's development of aquatic products breeding as follows: achievement by 1990 of an annual output of 510,000 tons of freshwater fish, an annual incremental increase of 8.9 percent, and an annual output of 16,000 tons of marine bred aquatic products by 1985, more than double the output of 1980.

During the conference, delegates focused attention on the problem of how to hasten the breeding of aquatic products, diligently summarized and exchanged advanced experiences, and acknowledged that the future freshwater fishing industry development program should mobilize all forces, make use of all kinds of water surfaces, strive to increase quantities and quality, and institute a combination of breeding, increased breeding, raising, and catching, with breeding being paramount. During the short run, major emphasis should be given the crucially important pond raising of fish with development and use of mountain ponds, reservoirs, and rivers for the raising of fish, and the promotion of the raising of fish in ricefields for gradual increased breeding of river resources, with support to commune members in the use of scattered water surfaces for the development of the household raising of fish to make full use of the potential of large and small water surface resources. The conference emphasized, in the development of aquatic product breeding industries, the need for adherence to the promotion and perfection of various forms of specialized contracting responsibility systems, to permit and protect individuals, organization, industrial plants, entreprenurial units and social groups in individual or collective use of funds under centralized planning for jointly managed breeding enterprises in vigorous development of large and medium size city and suburban raising of fish. The conference emphasized mobilization and organization of manpower, material, and financial resources from every quarter of society to solve the problem of funds for development and use of resources. In addition, serious attention should be given promotion of multiple measures for the raising of fish that interrelate the fishing industry, livestock raising, and agriculture, to emulating Gaoyao County's all out efforts with various forms of joint operations for the development of the fishing industry and the livestock industry, as well as Doumen, Sanshui, and Xinhui counties' experiences in combining improvement of farmland with the raising of fish, the raising of livestock and poultry, and farming to build a fine ecocycle system, the better to obtain benefits from multiple operations.

The conference noted that under present circumstances wherein inshore resources have been damaged while the broad marine coastal shallows have not yet been put to use, the fishing industry in all places must resolutely overcome tendencies toward, "emphasizing catching and slighting breeding," and implement a program of simultaneous emphasis on catching and breeding for active development of marine breeding. It is necessary, first of all, to implement and consolidate, with all possible speed, utilization rights to marine coastal shallows, to safeguard a stable production order, to put to use with all possible speed shallows not yet in use and, along with an expansion of the area, to take a path of development that links the long range and the short range, using the short range to nurture the long range, and going from extensive to intensive raising of aquatic products. Hastening development of marine shallows and use of coastal fishing grounds requires further emancipation of the mentality and liberalization of policies. In addition to state owned or collective operations or joint operations, a free hand might be given to various forms such as use of individual funds or use of group funds in contracting of operations as a means of stirring the enthusiasm of all parties. In existing state owned breeding grounds, a program must be put in place of "one industry primarily, with economic diversification and multiple use," efforts made to increase economic benefits and to make the most of the role of demonstrations by mainstay cadres, giving support to communes, brigades and commune members in skills, funds, and the breeding of fry [or larvae] so that marine breeding will be undertaken by the state, collectives, and individuals together.

Commentary on Spurring Development

Guangzhou NANFANG RIBAO in Chinese 17 Jun 82 p 1

[Text] The Guangdong Provincial People's Government recently convened a provincial work conference on aquatic products breeding, which acted on the basis of national plans and concrete conditions existing within the province to formulate guidelines for the province during the 1980's including an annual 8.9 percent incremental increase in freshwater aquatic products output, and a doubling within 5 years of marine breeding output. It also put forward corresponding programs, policies, and measures. This plan both meets the needs of the country and the people, and is also founded on favorable objective conditions. It is workable and can be achieved with effort. It is hoped that all levels of party and government organization will conscientiously carry it into effect.

Development of an aquatic products breeding industry relates to the large issues of full and rational use of natural resources, to in breadth and in depth progress in agricultural production, and to bringing into being a benign agricultural ecocycle. Modern large scale agriculture consists of the all around development of multiple activities in farming, forestry, animal husbandry, sideline occupations, and fisheries. Only by putting mountains, waters, and fields to use can great increases in commodity production be realized to satisfy market needs and to make sensible changes in people's diet. Additionally, only in this way can the rural economy flourish and outstanding increases take place in collective and individual earnings so that the broad masses of peasants can become propserous with all possible speed. It is from the strategic height of building and developing large scale modern agriculture that we must understand the importance of accelerated development of aquatic product enterprises, and give the same serious attention to utilization of every tract of water surfaces that we give the farming of every mu of cultivated land.

Guangdong Province has a very long coastline, and rivers traverse the land. More than 10 million mu of water surfaces are available for use providing a vast area for development of aquatic products breeding. However, practice has demonstrated that if these water surfaces are to be developed rapidly for use and outputs of fish increased, sole reliance on state-owned fisheries and specialized communes and brigades will not work. The masses in their millions must be aroused and relied upon, with state-owned enterprises, collectives, and individuals going forward together to carry out a guiding mentality of "mobilization of forces in every quarter," and arousing positive elements everywhere. This is to say that while operating state-owned aquatic products breeding grounds, communes, brigades, and commune member households have to be aroused for active development of the aquatic products breeding industry. It is necessary, as well, to encourage government organizations, groups, industrial enterprises and such social forces to act on the principles of voluntary participation and mutual benefit and equitable division of benefits, those having money investing money, those having materials investing materials, and those having skills investing skills, pooling the wisdom and efforts of everyone to join in aquatic products breeding enterprises. Only in this way will it be possible to win success in fairly rapidly development of the province's aquatic products enterprises.

In order to truly carry into effect a guiding mentality of "mobilization of forces in all quarters" for development of aquatic products endeavors, it is necessary to propagandize with great fanfare the necessity and the correctness of so doing so that the broad masses of peasants and elements in society concerned will give active support. It must be clearly announced that individuals, government organizations, industrial plants, enterprises, entreprenurial units and social groups may, under centralized management and after going through legal procedures, use their own funds collective funds for operations, or carry out joint operation of fishing industries, the rights of both investors and operators being guaranteed by law. During recent years in some places in Guangdong Province instances of economic units with different systems of ownership using diverse forms of joint development and operation of aquatic product hatching industries have taken place (such as industrial plants and production teams, state-owned commercial units and communes or brigades, and government organizations or groups and farms). These have achieved very good economic results, have increased commune, brigade, and farm earnings, and have improved supply of nonstaple foods to industrial plants and government organizations and groups. Otherwise unused water surfaces have also been put to use. Such methods are very inspiring and should be encouraged and given support.

For various historical reasons, utilization rights for most of the marine shallows of Guangdong Province have never been clearly defined, with the result that disputes can easily occur that seriously impair production order and are bad for arousal of enthusiasm for production of all quarters. Consequently, active and dependable implementation of utilization rights for these shallows is a fundamental task, and also a priority one. It is hoped that all jurisdictions will place it on their daily agenda of important things to do and organize forces for commune by commune and brigade by brigade implementation, seeking to complete the task within 1 or 2 years in accordance with plans drawn by this provincial work conference on aquatic products breeding. Predictably places that most quickly institute utilization rights to shallows in accordance with policies will be the ones most quickly to see the dawn of an aquatic products breeding industry.

Fishpond output in Guangdong Province is very unbalanced. Prefectures with fairly high yields get more than 400 jin per mu; low yield prefectures get only 100 jin or so. Such a difference domonstrates clearly that promotion of advanced fish raising techniques and administrative and management methods, and encouragement of scientific raising of fish are important ways in which to increase fish output fairly rapidly. Efforts of this kind hold great promise, and we must take account of realities in each prefecture, and come to grips with the major contradictions in them. Right now one-third of the province's fish ponds are shallow (a water depth of less than 1 meter), leaky, or small. We must improve them little by little over a period of time so that they become consistently high producing ponds. We must take account of the decline of certain fish varieties and adapt general methods to local situations for the promotion of new varieties (such as wealth and longlife fish [4395 1108 7625], and actively conduct experiments with new kinds of fry [or larvae]. Supplies of large quantities of good quality mixed feeds are a prerequisite for large scale breeding of aquatic products, and party and government leadership organizations should organize departments concerned to study and produce such feeds. For many years many places in the province have practiced a combination of fishing raising and hog raising, the raising of chickens, ducks, and geese, and the growing of mulberry and sugarcane for continuous production, which has helped maintain agriculture's ecological balance and has provided feed, making the aquatic products breeding industry and other breeding industries mutually supportive. Such scientific methods should be spread through the adaptation of general methods to local situations.

In short, we have to mobilize forces in all quarters, make full use of all kinds of water surfaces, promote scientific techniques, encourage multiple operations, and seed economic effectiveness. In this way we will definitely be able to make larger and more rapid strides in development of the province's aquatic products breeding industry in accordance with requirements of central authorities.

COUNTY SUMMER WHEAT OUTPUT UP BY 50 PERCENT

Shijiazhuang HEBEI RIBAO in Chinese 5 Jul 82 p 1

[Article: "Jize County Total Summer Output Up 50 Percent Over Last Year. Implementation of Policies Provides Reassurrance and Encourages Efforts; Scientific Farming Advances Increased Yields"]

[Text] Jize County, whose wheat production has always been very low, last year produced a total of 60 million jin from 192,000 mu, a better than 50 percent increase over last year, yields per unit of area reaching an all-time high. Every one of the 10 communes in the county had increased yields.

One major experience enabling Jize County to reap a bumper harvest this year despite numerous disasters was that the County CCP Committee and government took firmly in hand the consolidation and perfection of agricultural production responsibility systems, clearly publicizing no change in the already established various forms of production systems. The broad masses of commune members ceased to worry and courageously contributed money for the purchase of chemical fertilizer, machines, and tools for the development of productivity and to provide material conditions for increases in wheat yields. In addition, this county promoted fine varieties, increased fertilization with phosphate, and watering to combat drought better than in former years. The growing of Taiyi, Taiwu, Pinsanjiu, and Jimai Ershisan fine wheat varieties, which are suited to local soil conditions, was spread virtually everywhere in the county, and fertilization with phosphate was increased from the former 17 to 60 jin per mu, the soil's serious phosphate deficiency thereby being corrected. By sinking more pump wells and refitting deep well pumps, the irrigated area was enlarged by 30,000 mu making possible an increase by one or two waterings and as many as nine during the wheat's growing season.

PREFECTURE ORGANIZES FOR BUMPER GRAIN HARVEST

Shijiazhuang HEBEI RIBAO in Chinese 17 Jul 82 p 1

[Article: "Hengshui Prefecture Studies Formulation of Measures to Win Bumper Fall Harvest. Centers on Perfection of Responsibility Systems to Solve Problems in Production Relationships"]

[Text] Between 3 and 6 July, the Hengshui Prefecture CCP Committee and government administrative offices convened a conference of commune secretaries from throughout the prefecture. After summarizing experiences in harvesting a bumper summer crop, they studied and acted on the problem of how to redouble efforts to win an all around bumper fall harvest.

The conference agreed that in order to win a bumper fall harvest, attention will have to center on further improvements in the production responsibility system for the fall to make full use of the enthusiasm of collectives and commune members. First, summer contract agreements will have to be resolutely honored while at the same time fall contract agreements will have to be signed. There can be no shillyshallying. Second is doing a further good job management responsibility systems for pump wells, drainage and irrigation machines, and major water conservancy facilities. One-fourth of the prefecture still has no responsibility system for pump wells, and this is where the potential for combat against disaster to win a bumper harvest lies. No matter the form of responsibility system practiced, wells and machines are to be under the centralized management of production brigades or production teams. Third is establishment of an insect eradication responsibility system for centralized formulation of pesticides, for taking unified action at a given time, and for household by household elimination. Fourth is doing a good job of responsibility systems for drainage of waterlogging and prevention of floods.

While further perfecting various kinds of responsibility systems, this prefecture has also emphasized attention to key fields and key crops. The prefecture has more than 3 million mu of irrigated land for which the increased yield potential is very great. These are key fields for the winning of an all around bumper fall harvest. The prefecture has more than 5 million mu of fall grain crops, more than 3 million mu of which is corn. These are key fall grain crops for which the increased yield potential is very great. In this connection, the prefecture decided to give strict attention to key fields, appointing people responsible for them at every level in the institution of a system of individual responsibility. All communes have adoptnd a system whereby leading members of its CCP Committee are responsibility for certain tracts, whereby regular cadres are responsible for certain villages, whereby production brigade cadres are responsible for certain production teams, and whereby production team cadres are responsible for certain households in a level by level distribution of responsibility. Responsibility for key fields and key crops is apportioned to individuals, and is fixed through the use of rewards and penalties, and the use of agreements. All communes and brigades are to widerangingly arouse the masses to formulate measures for increasing yields of key fields and key crops, to concentrate water and manure, to give painstaking care, to do scientific farming, and to use every available means to win high yields. In addition, key fields are to be used for demonstration purposes to spur on the farming of ordinary fields for all around increases in yields. This prefecture has also made one of its major actions assistance to hardship production teams and hardship households in doing production to win a bumper fall harvest. It has required CCP committees and governments at all levels to place on their daily agendas help to the poor and assistance to those suffering hardships, with regular study, and persons designated responsible. Communes have directed attention to hardship production teams, and cadres, party members, and members of the Communist Youth League have been assigned to look after the families of revolutionary martyrs and servicemen and hardship households with many members but few workers or those who do not understand techniques and cannot make a living, helping them formulate measures to increase yields, teaching them farming techniques, and giving them needed support with workers, fertilizer, pesticides, and funds to solve various real difficulties.

PREFECTURE'S EFFORTS IN FACE OF MULTIPLE NATURAL DISASTERS OUTLINED

Shijiazhuang HEBEI RIBAO in Chinese 16 Jul 82 p 1

[Article: "Shijiazhuang Prefecture Strives to Win Bumper Fall Harvest in Agriculture. No Dejection When Disasters Strike, Measures Keeping Apace"]

[Text] In view of various natural disasters that have taken place, the Shijiazhuang Prefecture CCP Committee and government administrative offices has undertaken indoctrination of the broad masses of cadres and people in the prefecture on "man can conquer nature" to stir the people to stubborn struggle to conquer disasters and win a bumper fall harvest in agriculture.

During the first half of this year, agricultural production in Shijiazhuang Prefecture has sustained serious natural disasters including low temperatures, drought, hot dry winds, diseases and insect pests, and hailstones, which have reduced summer grain yields and have occasioned quite a few hardships for the winning of a bumper fall harvest. The Prefecture CCP Committee and government administrative offices promptly convened a prefecture wide agricultural work conference to analyze the disaster situation and to summarize the lessons of experience over the years in combating disasters to win bumper harvests. They mobilized people throughout the prefecture to resolutely fight to victory in the struggle against disasters to win a bumper harvest. Comrades attending the conference diligently analyzed the various favorable factors: First, as a result of further perfection of various forms of responsibility systems, the sentiments of cadres and masses are stable and zeal for combating disasters to win a fall harvest is very high. Second, for the past several years fall crop output has tended to increase steadily, and both cadres and the masses have accumulated experiences in winning a bumper fall harvest. Third, autumn grain production for the prefecture as a whole is very unbalanced and a great potential exists. Fourth a good basis exists for production this fall: the wheat has ripened early; fall sowing of grain has been 6 or 7 days earlier than in most years; and material conditions are also better than in former years. Despite the large area of hailstone damage, the time of the disaster was fairly early, so the situation can be reversed with effort, and confidence increased in being able to win a bumper fall harvest through hard work. After the conference, each county convened three cadre conferences in which a look back at the past and summarization of the lessons of experience were used as methods to stir the fighting will of cadres and the masses.

Simultaneous with indoctrination of the people of the entire prefecture in "man can conquer nature," the CCP Committee and government administrative offices proposed four key measures for winning a bumper fall harvest as follows:

1. Attention to medium and low yield areas for even increases in yields. Five counties in the prefecture including Zhengding and Wuji have grain fields with fall yields of 500 jin per mu, but nine counties produce yields that are lower that the prefecture average yields per mu, the lowest county having yields of only 283 jin per mu. The Prefecture CCP Committee and government administrative offices have given practical assistance to these medium and low yield counties in studying the formulation of measures to increase yields, and to catch up with and overtake advanced levels. They are working to obtain yields of 550 jin or more per mu from the prefecture's 3.5 million mu of cornfields for an output totaling 2 billion jin.

2. Spurring high yields from areas in which disasters were slight, using bumper production to offset lean production. In Lioncheng and Huolu counties, natural disasters were relatively light and the Prefecture CCP Committee has called upon them to increase their grain production. Now these counties are taking effective measures in an effort to produce more, carrying the responsibility for the whole prefecture.

3. Strict attention to production of grains other than wheat and rice, using every available means to grow and harvest more. Particular attention has been devoted to potatoes and millet as key crops. The "10 besides" [beside villages, streams, fields, houses, roads, etc.], odd bits of land, and every place that can b sown have been fully planted in an effort to increase the harvest somewhat.

4. Economic diversification centering on cotton has been launched. The prefecture's cotton was fairly hard hit, and each county has taken the measures appropriate to different kinds of cottonfields. Where it had to be destroyed, it was destroyed; where it should be intercropped, it was intercropped, and what remained was given increased care in an effort to insure that there would be no reduction in total cotton output for the prefecture as a whole. In addition, everywhere both the collective and individual commune members worked together using every available resource to expand production avenues and to develop economic diversification that would produce fast results and large benefits in an effort to realize a 100 million yuan increase over last year in total earnings from agriculture, and average per capita earnings of 190 yuan (the collective distributing 130 yuan and income from household sideline occupations amounting to 60 yuan).

SUGGESTIONS MADE ON SOLVING GRAIN PRODUCTION PROBLEM

Shijiazhuang HEBEI RIBAO in Chinese 8 Jul 82 p 1

[Article: "How Can the Problem of 'Two Lates and Two Reductions' in Grain Production Be Solved. Three Science and Technology Personnel in Shijiazhuang Prefecture Provide Five Suggestions Following Investigation and Study"]

[Text] Science and technology personnel, Li Yashen [2621 0068 3234], Yang Fuchuan [2799 1381 1557], and Wei Xidao [7614 0823 6670], from the Shijiazhuang Prefecture Science and Technology Information Institute conducted investigation and study in seven counties including Zhengding, Luancheng, Pingshan, and Yuanshi and explored problems with "two lates and two reductions" in the prefecture's two crop grain production system after which they proposed five ways in which to solve the problems. Shijiazhuang Prefecture government administrative offices adopted their suggestions and notified the entire prefecture, and now some counties and communes have begun to take action to solve these problems.

Shijiazhuang Prefecture's multiple grain sowing index is 186 percent. Throughout the prefecture mostly wheat is grown winter and spring, and corn grown summer and fall. Tremendous growth has taken place in grain output only to have problems with "two lates and two reductions" occur. Since the quantity of heat resources required and growing of multiply sown crops are not mutually compatible, low temperatures cause the corn to delay development and ripen late, and during the late growth stage low temperatures cause cold damage. The growing season is extended by 5 or 6 days, and the ripening period for corn in open fields is delayed from late September until early October. Low temperatures are bad for filling out and ripening; the per thousand kernel rate declines, and yields are low. Late ripening of the corn leads to late sowing of the wheat and a delay in the growing season with low yields. In addition, problems exist in a not completely rational farming system, corn varieties requiring a long growing season, and slapdash care of crops.

Following investigation, the three science and technology personnel made five suggestions for solving the problem of "two lates and two reductions." One was adherence to a farming system featuring intercropping. Intercropping is able to make better use of light and heat resources than the sowing of two entirely separate crops, and resistance to disaster is strong. Since the growing season is long, intermediate ripening or intermediate and early ripening varieties with great potential for increased yields may be grown to stand a better chance of getting increased yields. Second is adaptation of general methods to local situations to do a good job of regionalizing the distribution of varieties in the farming system. On the basis of diverse climatic conditions resulting from differences in elevation above sea level, Shijiazhuang Prefecture's farming system may be divided into four major zones: The plain at the eastern foothills of the Taihang mountains and parts of the gently sloped hill region, which is a zone for two crops per year of intercropped intermediate ripening varieties; the Taihang Range frontal mountains and hill zone, which is a zone for two crops per year of intercropped early ripening varieties; the cold zone in the mid-section of the Taihang Mountains, which is a zone for the growing of two intercropped crops per year; the high frigid mountain zone of the western Taihang Mountains, which is a one crop per year zone. Distribution of varieties in each area must fit in with local natural conditions. Third is readjustment of the sowing season, earlier sowing being done so that summer corn may be harvested early and in good time to assure the sowing in good time of winter wheat. Fourth is a reduction in the waste of farming time. At the present time, time wasted on the three autumn jobs [harvesting, plowing, and sowing] in Shijiazhuang from the time that the summer corn is harvested until the winter wheat is sown) is generally 11 to 17 days for a waste of between 200 and 300 degrees Centigrade of cumulative heat, which is a major factor affecting the on-time sowing of wheat, and the growing of sturdy seedlings before the onset of winter. Shortening of the waste of farming time requires active promotion of direct return to the fields of stalks and stems to save the work time required to haul the stalks away, the composting of coarse manure, and the reverse hauling of manure to the fields. This would both help accelerate the fall harvest and fall sowing, and would help nurture soil fertility to increase crop yields. In addition, it is necessary to make full use of and bring into play the role of farm machines, to strengthen management, and to promote responsibility systems to gain time for on-time early sowing. Fifth is early care during the seeding stage to promote early ripening. When corn is intercropped with wheat, during the early period when both are growing, the young corn seedlings are yellow and weak and they lack water and fertilizer. After the wheat has been harvested, temperatures are high and the air is dry; a great amount of evaporation takes place and the soil is leathery, so the importance of early care is greater. If watering and topdressings of fertilizer are not promptly given, the debris from the wheat crop cleared away, and thinning and weeding done, not only will there be no early harvest, but seedlings may die from parching or may not develop.

GOOD HARVEST REPORTED IN BAODING PREFECTURE

Shijiazhuang HEBEI RIBAO in Chinese 14 Jul 82 p 1

[Article: "Baoding Prefecture Wins Bumper Summer Harvest in a Year of Many Disasters. Summer Grain Growing Area Down by 570,000 Mu From Last Year but Total Output up by 100 Million Jin"]

[Text] Despite multiple natural disasters including drought, hot dry winds, and aphids, Baoding Prefecture reaped a fairly good harvest this year from its 5.92 million mu of summer grain crops. Though the area sown was down 570,000 mu from last year, total output amounted to about 15.9 billion jin, up by about 100 million jin from last year.

The main reason for Baoding Prefecture's fairly good summer grain harvest this year was further arousal of the enthusiasm of the broad masses of cadres and people as a result of the reorganization of grassroots leadership teams and the perfection of responsibility systems. Since the lunar new year, prefecture and county leaders have taken the lead in the transfer of large groups of cadres to the grassroots to do a solid job of solving problems of paralysis and semi-paralysis in the leadership teams of more than 700 production brigades and more than 9,600 production teams, and to re-collect collectively owned property that had been dismantled and dispersed in more than 3,100 production teams. In production teams where no withholdings were made last year, withholdings were instituted, and pump well management and irrigation responsibility systems were promoted pretty much everywhere. In addition, leaders and technical departments at all levels used all available means to spread scientific techniques to thousands upon thousands of households. In the prefecture's 23 counties (or municipalities), 522 technical cadres instituted responsibility systems wherein technology was linked to output, contracting the farming of a land area of more than 170,000 mu. The prefecture and counties used various ways in which to give on the job training to 146,500 farm technical personnel. They also prepared, printed, and distributed large quantities of technical data in vigorous promotion of scientific wheat care. Many counties and communes used the study of advanced techniques to change the method of fertilization from "many feedings a little at a time" to "heavy fertilization with greening up fertilizer." More and more people also became familiar with phosphate fertilizer, and this year the wheatfield area of the prefecture fertilized with phosphate fertilizer amounted to 3.64 million mu, a 640,000 mu increase over last year, a total of 152,000 tons of phosphate fertilizer being spread, more than 30,000 tons more than last year. All trades and industries vigorously supported the fight against drought to water the wheat. During this year's drought when supplies of electric power and fuel were inadequate, watering was done no fewer times than last year.

PROVINCIAL NOTICE ON PESTICIDE USE ISSUED

Shijiazhuang HEBEI RIBAO in Chinese 14 Jul 82 p 1

[Article: "Provincial Government Issues Notice Requiring All Jurisdictions To Intensify Plant Protection Work and Guard Against Pesticide Poisoning"]

[Text] Recently the provincial government issued a notice titled, "Intensify Plant Protection Work and Guard Against Pesticide Poisoning." The notice required all jurisdictions to do a genuinely good job of establishing grass-roots level plant protection organizations and plant protection technical corps, to fully staff and to strengthen commune stations for the promotion of techniques. It required production brigades and production teams to have peasant plant protection personnel, encouraging them to sign agreements with production teams or commune member households for the prevention and control of insect pests and diseases, and to satisfactorily solve problems in their remuneration.

The notice pointed out the need to actively develop plant protection companies and to promote vigorously agreements for prevention and control. Plant protection companies should use agreements to contract disease and insect pest prevention and control tasks, technical personnel being responsible for technical guidance, production units being responsible for the implementation of prevention and control measures, both parties to agreements bearing individual economic responsibility to improve results in disease and insect pest prevention and control. County plant protection companies should both direct plant protection work throughout the county and should make contractual agreements for prevention and control.

Pesticides are to be used scientifically and safely. No matter the form of production responsibility system practiced, prevention and control of diseases and insect pests is to be centrally organized. The system of organization should proceed from realities and general methods adopted to specific situations in a seeking after genuine results. Either the production brigade or the production team may be the unit designated responsible for centralized inspection of insects, centralized purchases of pesticides, centralized management of pesticides, centralized mixing of pesticides, and centralized organization of prevention and control, individual households paying prevention and control fees on the basis of their area of prevention and control. Alternatively 35 households or a few score households can band together freely under the leadership of a technical demonstration household for cooperative prevention and control. The notice also required agricultural, supply and marketing, medical and health, propaganda, educational, and cultural departments to exert joint efforts and to adopt various methods for broadly and deeply publicizing knowledge about scientific and safe use of pesticides, to give technical training, and to increase the technical levels of the masses of commune members as quickly as possible in the use of pesticides for the prevention and control of diseases and insect pests.

HOEING, FERTILIZING UNDER WAY IN ZHANGJIAKOU PREFECTURE

Shijiazhuang HEBEI RIBAO in Chinese 14 Jul 82 p 1

[Article: "Zhangjiakou Prefecture Takes Firm Grip on Key Measures in an Effort To Provide Good Summer Crop Care"]

[Text] The broad masses in Zhangjiakou Prefecture have responded to the call from the Prefecture CCP Committee and government administrative offices for "an all-time high overfulfillment of agricultural production" launching a 100-day campaign of summer crop care in which the pace and quality of summer crop cultivation and fertilization has been better than in previous years.

After the Zhangjiakou Prefecture CCP Committee and government administrative offices issued an open letter on the prefecture's having "an all-time high overfulfillment of agricultural production," all levels formulated measures one after another, took firm hold of key areas, and worked as one to wage a 100 days war, with a stirring situation of "three manys" appearing in summer crop care. One was many workforces on the job, the prefecture fielding more than 720,000 people for summer crop care, making it an all-time high year for workforces on the job. Second was many working hours with many commune member households going into the fields early and finishing late, taking their noon meal in the fields, and working 14 or 15 hours daily. Third was many farm tasks done. As of 25 June, the prefecture had cultivated 9,214,000 mu of seedlings, 2,136,000 mu more than last year. So far 2,332,000 mu have been cultivated twice, 1,054,000 mu more than during the same period last year. Many contracting households have cultivated four or five times.

Since it has rained a great deal lately and the seedlings are growing rapidly, this prefecture has taken a firm grip on topdressings of fertilizer as a key measure for increasing yields. Zhuolu County has called for early topdressings, heavy topdressings, deep topdressings, and general topdressings of fertilizer, and has allocated 3 million yuan in loans for fertilizer. The county has already applied topdressings to more than 260,000 mu. A first fertilization has been given to 81 percent of the corn, gaoliang, and wheat crops, and 110,000 mu have been fertilized twice. The Xuanhua County Bank of Agriculture and credit cooperative have transferred the handling of loans for the purchase of chemical fertilizer from commune credit cooperatives to production brigade credit cooperatives. The county's 28 grassroots level supply and marketing cooperatives retail chemical fertilizer and are on duty day and night to take care of all comers. All plains conties have stirred the masses to fertilize with sheep, goat, and chicken manure. Today the area of the prefecture that has been fertilized once amounts to 650,000 mu, exceeding the same period last year by 73 percent. The area fertilized twice amounts to 138,000 mu.

PREFECTURE FARM MACHINERY MANAGEMENT IMPROVEMENTS REPORTED

Shijiazhuang HEBEI RIBAO in Chinese 6 Jul 82 p 2

[Article: "Centralized Production, Sale, and Management of Farm Machinery Products"]

[Text] Editorial Department: Farm mechanization has developed very rapidly in Shijiazhuang Prefecture during the past several years. One well per mu fully equipped with pumps and electricity, more than 80 percent of the wheat growing area sown by machine, and more than 40 percent harvested by machine have been fairly balanced with little overstocking in warehouses. A search for the reason reveals that it has resulted principally from promotion of a centralized system throughout the prefecture in the production, sales, and management of farm machinery. Formerly farm machinery production was the province of the Prefecture Machinery Bureau; sales were the province of the Farm Machinery Company, and administration, management, use and promotion were the province of the Farm Machinery Management Bureau--a division among the industrial, commercial, and agricultural systems. Every year when it was time to lay plans during the fourth quarter for the following year's production, though discussions were held among all three, each took a stand on his own position, product plans could not be readjusted on time, and when problems were encountered there was mutual squabbling to the serious detriment of the development of farm machinery. Beginning in 1976, the prefecture merged the Farm Machinery Management Bureau and the Machinery Bureau into the Machine Industry Bureau, and the Farm Machine Company came under the direction of the Machinery Bureau, the production, sales, management and use of farm machines thereby being unified for fine results.

First, it was possibly to make centralized production plans. The Machinery Bureau organized personnel in advance to go down into the grassroots levels to conduct market investigation and forecasting. Next the production planning section produced production plans, which the Bureau leaders discussed and decided on in a meeting of units concerned.

Second, production and sales were organically linked. In 1980 the Prefecture CCP Committee made 35 percent of the prefecture harvest wheat by machine, but wheat harvesting machines did not sell rapidly. The Machinery Bureau CCP Committee, thereupon, convened a meeting of units concerned to study the matter and centrally transferred personnel from the Farm Machinery Company, the Farm Machinery Section, the Drainage and Irrigation Section, and the Production Section to sell the products. The Bureau director directed his main energies to grassroots work. In this way, efforts were made equally by those in charge of sales and those in charge of production, and suddenly 3,500 sales occurred.

Third was elimination of contention between producers and users. Last year at wheat harvest time when Farm Machinery Section comrades promoted experimental use of wheat harvesters in rural villages, it was found that the auxiliary paddle-wheel on the special-shaped auxilliary plate was at the wrong angle, with the result that the harvested wheat was somewhat blocked and did not come out in a regular flow. They worked with the operator to try to straighten out the problem, and immediately reported the problem to the producing factory.

Fourth was timely readjustment of production plans. It had originally been intended to produce 112,000 harvester and threshing machine spare parts this year, but the Planning Section suggested a change to 113,000. Later it was realized that harvesting machines alone would require 180,000 spare parts, so bureau leaders raced to make new arrangements to make sure that the machines positively would not lack spare parts and that wheat harvest needs would be met.

Fifth was elimination of product quality and price differences. For the past several years the Farm Machine Company has been dissatisfied with the quality of deep well pumps produced by the Huolu County Water Pump Plant, and the plant generally felt that there was a ready market for its products and so did not give attention to the quality problem. The Machinery Bureau transferred some technicians to conduct studies with the plant and reasons for impairment of quality were found, making it possible to solve the problem. Products bounded into a top grade position. When the state ruled that diesel engine prices could be lowered 35 percent, Shijiazhuang Prefecture studied the matter and ruled that for purchases of more than 300 machines, prices would be lowered 30 percent, and for purchases of more than 500 machines prices would be lowered 35 percent with no squabbles resulting.

BRIEFS

PARTIAL DROUGHT RELIEF--From the evening of 8 July until 8:00 a.m. on the morning of 10 July it rained everywhere in the province except for Tangshan Prefecture. In south central Baoding Prefecture, eastern Shijiazhuang Prefecture, northern Xingtai Prefecture, northern Hengshui Prefecture, and western Cangzhou Prefecture from 25 to 144 mm of rain fell, Shen, Gaoyi, Chao, Ningjin, Boxiang, and Shulu Counties receiving more than 100 mm. Other areas received little to moderate rainfall. Ever since late June little rain has fallen in the province, and in some places the specter of drougth has risen. This recent rainfall will improve soil moisture conditions and be extremely beneficial for agricultural production. However, in western Xingtai Prefecture, western Handan Prefecture, and in the old drought areas in the southern part of the province, rainfall has been less than 4 millimeters and drought conditions continue unabated. PROGRESS REPORT ON SONGHUA JIANG POLLUTION CONTROL

Editorial Comment

Harbin HEILONGJIANG RIBAO in Chinese 10 Jul 82 p 1

[Editorial: "We Must Do Well in Bringing Songhua Jiang Pollution Under Control"]

[Text] Reading the news that the work of controlling pollution of the Songhua Jiang has achieved initial success is very inspiring and encouraging. This marks a fine beginning in bringing under control pollution of the Songhua Jiang, and is glad tidings for the millions of peasants who live in the Songhua Jiang basin.

Though much has been accomplished in bringing pollution under control in the Songhua Jiang water system, looked at in terms of full control of pollution in the water system, this work is but a first step. Many formidable tasks await completion. We must establish a mentality of protracted war because of the following: Pollution by some of the major sources of pollution has only been reduced but not totally cured. Control of some major pollutants, such as mercury deposits, is not something that can be completed in 2 or 3 years, but rather protracted and arduous efforts will be required. In the two provinces of Jilin and Heilongjiang, and in Nei Monggol tens of thousands of enterprises directly pollute the river, and control projects to be completed within a specified period of time cover only 20 percent of the total amount of polluted water. Pollution by an overwhelming majority of enterprises has yet to be controlled or cleared up. Pesticide pollution, pollution by hospitals, and pollution by waste water from the people on the several hundred square kilometers of land along the river has not been fundamentally controlled. Some of the newly constructed enterprises have not put into effect the "three concurrents" [provisions for eliminating pollutants as an integral part of production processes], so they add new pollution. Therefore, it is necessary to handle the treatment of Songhua Jiang pollution as a long-term task that has to be adhered to in a protracted struggle against pollution. We must make up our minds that there will be no slackening of efforts until pollution has been eliminated, and that there will be no rest until the river water is clean, and be determined to clean up pollution of the Songhua Jiang!

Cleaning up pollution in the Songhua Jiang is an extremely urgent task. This is because of the seriousness of the pollution. Today, much of the industrial waste water that enters the river does not meet standards for discharge, and some of it exceeds national standards many times or tens of times over. The health of the mass of people is in danger. Moreover, as a result of pollution of the river water, machinery and equipment has been seriously corroded. This hurts product quality and interferes with development of industry, agriculture, and the fishing industry. Socialist enterprises have as their goal the creation of wealth for the people, but when they create havoc for the people and for posterity, does this not go against the goals of socialist production? Therefore, cleaning up pollution is not only a matter of professional morality for each individual enterprise, but is also something decided by the socialist system. We must have a sense of urgency. Every day gained in cleaning it up is a day of creating wealth for the people. Every day's delay is a crime against the people. Only by having a sense of urgency will one not wait or depend on others, but actively create conditions and devote urgent attention to the cleanup. Some advanced units have relied mainly on their own manpower, financial, and material resources, cleaning up pollution through self-reliance. Other units, on the other hand, emphasize subjective conditions, saying that if someone wants them to clean up the pollution, they should give them money to do it. Such an apathetic attitude must be overcome. Except for some comprehensive clean-up projects that the state and higher authority should support, for the overwhelming majority of medium size and small size projects for which the expenditure is not great, only by tapping the potential from within can the problem be solved.

Cleaning up the pollution in the Songhua Jiang is a task of very strong [two characters illegible] requiring not only a revolutionary spirit, but also requiring a scientific attitude. Pollution of the Songhua Jiang is, to a very great degree, the result of backward technology, [several characters indistinct] that has given rise to a waste of energy and resources. Thus, it is necessary to vigorously advocate scientific pollution control and to get results from scientific techniques. The work to be done in this regard is great. Production enterprises that seriously pollute must undertake major technical innovations and technical improvements, get rid of backward techniques, and substitute advanced new techniques. Large specialized institutions of higher education, scientific research organizations, and industrial and mining enterprises must organize and work together in an attack on some major scientific research topics, and departments concerned should lend support in manpower, material and financial resources for this purpose. Intelligence work on environmental protection has to be strengthened, and new techniques from abroad in the cleaning up of pollution promptly mastered, so the work we do can draw on this experience and gain impetus from it. Monitoring devices and methods should be augmented and monitoring centers set up to intensify monitoring of water systems to provide scientific evidence of changes in water system pollution as it occurs and to bring pollution under control.

Pollution of the Songhua Jiang is caused by countless units and departments. It affects areas in both the upper reaches and the lower reaches, and it affects industry, agriculture, business, and health departments, and all trades and industries. It is a social problem. Consequently, in order to clean up the pollution, it is necessary to mobilize all prefectures, all departments, and all trades and industries, to mobilize the masses of people, to make concerted efforts from top to bottom, and to take action together in every quarter. Only in this way will it be possible to halt and prevent pollution effectively. It is necessary to organize individual sectors into coordinated combat, break through regional lines, link together pollution, regions, and sections, and make mutual inspections in order to promote control. Widespread efforts must be made to arouse the people to build an environmental protection corps consisting of specialists, part-timers, and the masses to help supervise and inspect pollution and to control the situation. Only if all sectors of society and all forces are mobilized can greater results be achieved in cleaning up pollution.

In order to clean up pollution of the Songhua Jiang, it will also be necessary to adopt compulsory administrative actions and to use economic and legal methods. This is necessary in order to protect the people's welfare and to protect the welfare of society as a whole. The nationally promulgated "Environmental Protection Law (Trial)" and "Management Regulations on Collection of Fees for Discharge of Pollutants" are major administrative regulations for promoting a cleanup of pollution. All departments and enterprises must carry them into effect, make certain to maintain the solemnity of the law, and handle matters strictly in accordance with laws. All units that are to clean up in a certain period of time are to finish within that period of time. Where work cannot be finished in time as a result of lack of effort on the part of leaders, responsibility is to be fixed on leaders and economic penalties imposed.

Protection of the Songhua Jiang and cleaning up of the Songhua Jiang is a formidable, glorious, and great undertaking. It is a major component in our building of the two civilizations. Only by having grand and far-reaching goals the resolve to struggle for a long period of time, a firm and indomitable spirit, a work style in which our feet are firmly planted on the ground, and a strictly scientific attitude will we be able to eliminate pollution in the Songhua Jiang water system and bring about its early return as a beautiful, limpid river.

Conference Held

Harbin HEILONGJIANG RIBAO in Chinese 10 Jul 82 p 1

[Text] Under a new situation of readjustment of the national economy active and effective measures are to be adopted to achieve new levels in the job of clearing up the Songhua Jiang water system in an effort to achieve by 1985 a remarkable improvement in quality of water in seriously polluted sections of the river, a 60 percent processing rate for waste water, and a breakthrough in cleaning up mercury deposits in the river. This is the objective of struggle put forward to Jilin and Heilongjiang provinces by the Third Songhua Jiang Water System Protection Conference.

The Third Songhua Jiang Water System Protection Conference was held in Qiqihaer from 2 to 5 July. A total of more than 500 persons in charge in the various commissions, departments and bureaus of Jilin and Heilongjiang Province, persons in charge in various provincial government administrative offices, municipalities, and counties, as well as delegates from individual major industrial and mining enterprises and entreprenurial units along the river attended the conference.

Chen Xiping [7115 6007 1627], representative from the national Ministry of Urban and Rural Construction and Environmental Protection, and delegates from other national ministries and commissions involved, as well as persons in charge of departments concerned in the Nei Monggol Autonomous Region also participated in the conference.

The unit chief of the Songhua Jiang Water System Protection Leadership Unit and Jilin Province vice provincial governor, Dong Xin [5516 2500], made a report to the conference on behalf of the unit. The deputy director of the leadership unit, Heilongjiang Provincial CCP Committee secretary and vice provincial governor of Heilongjiang Province, Chen Jianfei [7115 0494 7378] gave a speech at the conference.

This conference summarized accomplishments and experiences during the past 4 years in cleaning up the Songhua Jiang water system. It studied existing problems and measures for further prevention and control of pollution, proposing a goal for struggle between now and 1985. The conference asked all departments and enterprises concerned to link together the prevention and control of pollution of the Songhua Jiang with technical improvements in enterprises, using the technical improvements to solve, to the maximum extent possible, industrial pollution in the production process. It asked major sources of pollution to continue to take action to clean up within a limited period of time, and to hasten the pace of the cleanup, leaders of units unable to complete the cleanup on time being held responsible. Management of the water system is to be improved, both legal methods and economic measures being used to strictly control production and new pollution. In projects to be newly built, remodeled, or enlarged, the "three concurrent" regulations are to be enforced requiring concurrent designing, construction, and operation of projects and pollution control devices. Monitoring of water quality is to be intensified, and a good job done in scientific research on prevention and control of water pollution. Units who had made achievements in the prevention and control of Songhua Jiang water system pollution, including the Jilin Chemical Industry Company, the Mudanjiang Petroleum Refinery, the No 1 Automobile Manufacturing Plant, and the Qiqihaer Steel Mill gave briefings on experiences to the conference.

The Songhua Jiang Water System Leadership Unit issued banners of merit, certificates of merit and trophies to 29 advanced units and 25 advanced persons in Jilin and Heilongjiang provinces.

Pollution Control Achievements

Harbin HEILONGJIANG RIBAO in Chinese 10 Jul 82 p 1

[Text] The work of cleaning up pollution of the Songhua Jiang water system has achieved heartening results. Pollution has been brought under preliminary control; a great reduction has taken place in the quantity of pollutants discharged into the river; and water quality has improved remarkably. In the second stage of the Songhua Jiang where fish and shrimp had virtually vanished, schools of fish have appeared again; and in the Nen Jiang, where valuable fish were rarely seen for a time, an increase has taken place.

The Songjiang water system encompasses the second stage of the Songhua Jiang, the Nen Jiang, the Mudan Jiang, and several such large tributaries, the basin covering an area of more than 540,000 square kilometers. This is a water conservancy resource shared by Jilin, Heilongjiang, and the Nei Monggol Autonomous Region. With the building of industrial production following the 1960's, river pollution became increasingly serious. Daily more than 8 million tons of damaging effluent containing phenol, cyanogen, mercury, chromium, arsenic, alkali, and oil was discharged into the river posing a serious danger to agriculture, the fishing industry and the people along the river. In order to buttress the prevention and control of pollution of the Songhua Jiang water system, in 1978 the State Council approved the establishment by the governments of Jilin and Heilongjiang provinces and pertinent ministries and commissions of the central government of the Songhua Jiang Water System Protection Leadership Unit with responsibilities for overall planning of pollution and control on the Songhua Jiang water system. The leadership unit held a regular meeting once each year and also held three water system protection conferences for prompt summarization of the lessons of experience in pollution prevention and control, to solve existing problems, and to energetically give impetus to the work of pollution prevention and control on the entire water system.

In the process of cleaning up pollution on the Songhua Jiang water system, it directed attention to the major polluting cities, major sources of pollution, and the major pollutants. Under the centralized direction of the leadership unit, Jilin and Heilongjiang provinces designated three groups causing serious pollution and demanded that 140 enterprises and 187 projects causing the greatest damage clean up within a limited period of time. The Jilin Chemical Industry Company was the number one source of pollution in the second stage of the Songhua Jiang, discharging a large quantity of waste water containing numerous kinds of poisonous materials of high toxicity. In the process of cleaning up within a limited period of time, they took only 2 years time to build a waste water processing system capable of handling 192,000 tons daily, the first section of which has already gone into formal production. The second section is being feverishly worked on. Once this project has been completed, it will play a definite role in improving the water quality of the Songhua Jiang. Qiqihaer was the major polluting city in the mid reaches of the Nen Jiang, which has set up 95 projects within the space of 4 years for effecting a cleanup in a short period of time. The cleanup centers on the Qiqihaer Steel Mill, the No 1 Heavy Machinery Plant's effluent, which contains phenol, and the organic effluent of a sugar mill, a paper mill, and a main tannery plant. As a result, the phenol content of the Nen Jiang's water has become much lower than national health standards for surface water, and aquatic product resources have revived.

In the course of cleaning up Songhua Jiang water system pollution, many methods were applied to strengthen management of the water system. In the case of enterprises that seriously polluted and could not be readily brought under control, closures, suspensions, mergers, retooling, and relocation were done to solve pollution problems. In Nenjiang Prefecture alone, 11 industrial plants were relocated, and 15 plants were closed or suspended. Last year both Jilin and Heilongjiang provinces instituted a system of fee collections for discharge of pollutants. Enterprises whose pollutants posed great dangers were economically penalized. This aroused serious attention on the part of all levels of leadership about cleaning up pollution, and numerous enterprises took the initiative to start pollution control work and plug gaps creating pollution. In addition, after instituting the collection of fees for discharge of pollutants, some cleanup funds were collected, and during the past 2 years both Jilin and Heilongjiang provinces have used the fees obtained for discharge of pollutants to set up 235 clean-up projects in which they have invested 17.5 million yuan. In addition, for new construction, remodelling, and expansion of large and medium size projects, they have instituted a system of environmental impact reports, and have devoted great attention to implementation of the "three concurrents" for effective control over the production of new sources of pollution.

Under the centralized planning of the Waterway Leadership Unit, Jilin and Heilongjiang environmental protection departments have intensified monitoring of the Songhua Jiang water system. They have built 39 monitoring stations on the waterway equipping them with water quality monitoring boats and other devices and equipment for the preliminary formation of a Songhua Jiang water quality monitoring network. This will provide large amounts of monitoring data and technical material for understanding the waterway's environmental quality and for comprehensive prevention and control of pollution, playing a sentry role as eyes and ears. Jilin and Heilongjiang's science commissions and environmental protection departments have organized relevant scientific research units and institutions of higher learning to begin active research work on Songhua Jiang water system environmental protection. During the past several years, large groups of scientists and technicians have gone into industrial plants, rural villages, and seriously polluted stretches of the Songhua Jiang basin to survey the pollution situation and to study the danger pollutants pose to human health as well as to agriculture, the fishing industry, and organisms. It has already okayed 31 scientific research projects, 23 of which have been applied to pollution prevention and control. Tong He paper mill engineer Wang Deshan [3076 1795 1472] succeeded after 7 years of research on the new technique of electrodialysis of black liquid produced in paper making, recovering caustic soda to clean up pollution, obtaining both remarkable economic benefits and environmental benefits. Jilin Municipal Fuels and Chemicals Bureau assistant engineer Cui Yongjiang [1508 3057 3068] went into the No 3 Chemical Industry Plant to solve pollution problems involving waste water containing metaphyenylene diamine contributing his strength to increasing the country's wealth and protecting the Songhua Jiang.

STATUS REPORT ON NEN RIVER DIVERSION PROJECT POSTED

Harbin HEILONGJIANG RIBAO in Chinese 5 Jun 82 p 1

[Article: "Nen Jiang Diversion Project in Southern Heilongjiang Begins to Provide Benefits. Progress Made in Solving the Water Shortage Problem of the Western Prairie"]

[Text] The Nen Jiang River diversion in southern Heilongjiang Province, on which 80 percent of construction has been completed, already holds more than 160 million cubic meters of water to form a natural reservoir with a water surface larger than a mirror lake so that the farming, animal husbandry, sideline occupations, and fisheries of nearby communes and brigades can flourish.

Beginning during the 1970's, construction has continued on a project in the western part of the province on large northern, southern, and central diversions of the waters of the Nen Jiang to irrigate the western prairie. The southern Nen Jiang diversion project, on which construction began in 1977, is located on the left bank of the lower reaches of the Nen Jiang, and the diversion channels traverse the Zhaoyuan and Duerbo Counties, and the city of Daqing. This is a large water storage project for the benefit of agriculture, animal husbandry, sideline occupations, and the fishing industry. The waters diverted from the Nen Jiang are stored in eight natural ponds to form a continuous large reservoir. The amount of water currently impounded is about one-fourth the design requirement. Following diversion of the river waters, the natural and economic situation around the reservoir area began to change. The large increase in water surface brought good influences to this arid climate and promoted development of agriculture. The river waters brought abundant aquatic products. Last year alone, Lijiayao Second Brigade in Yaoxintun Commune in Duerbote Monggol Autonomous County caught fish in the reservoir and channel for earnings of 30,000 yuan. Reeds grow luxiantly along the reservoir shore, and last year a total of 14,700 tons of reeds were harvested from the reservoir area to increase earnings by 880,000 yuan. Grass quality on the prairie near the reservoir area has also begun to change. Grazing cattle and sheep are fat and sturdy.

Today the two counties and one city are both continuing attention to project construction and striving to increase benefits from the project as well. Communes and brigades concerned have already formulated comprehensive regulations for use.

NOTICE ISSUED FOR METHOD TO CLASSIFY PEASANT TECHNICAL PERSONNEL

Harbin HEILONGJIANG RIBAO in Chinese 6 Jun 82 p 1

[Article: "Heilongjiang Province Tries 'Peasant Technical Personnel Management Methods.' Classification as Peasant Technicians and Grade 1, 2 and 3 Peasant Technical Personnel With Testing and Assessment Before Year's End"]

[Text] Recently the Provincial People's Government issued a notice approving the "Heilongjiang Provincial Peasant Technical Personnel Management Method (Trial)" and called on all prefectures, municipalities, and counties, as well as departments concerned directly subordinate to the province, to do a good job of peasant technical personnel classification and evaluation work, carrying out testing and assessment of existing peasant technical personnel before the end of the year.

The management methods stipulated classification as peasant technician and as grade 1, 2 and 3 peasant technical personnel. Peasant technicians must possess vocational skills equivalent to levels at institutions of higher education, have more than 10 years practical experience in technical agricultural work, and be able independently to solve crucial technical problems in production. Grade 1 peasant technical personnel must possess vocational skills equivalent to the technical secondary school level, have more than 5 years practical experience in technical agricultural work, and be able independently to conduct experiments and demonstrations. Grade 2 peasant technical personnel must be able rather systematically to understand certain scientific and technical knowledge and operating skills, have more than 3 years practical experience in technical agricultural work, and be able to conduct experiments and demonstrations as required. Grade 3 peasant technical personnel must be able to understand in a preliminary way certain agricultural scientific and technical knowledge and operating skills and to be able to solve run of the mill technical problems in production.

Peasant technicians and peasant technical personnel classification is to be done by municipal and county peoples governments (farm machinery by provincial administrative offices and by cities), certificates being issued. Peasant technical personnel will be eligible for promotion once every 2 years, and those who have been classified will be subject to regular observation. The management methods also stipulated peasant technical personnel remuneration and technical subsidy methods.

NEED FOR ECONOMIC CROP QUALITY IMPROVEMENT ACCENTED

Harbin HEILONGJIANG RIBAO in Chinese 8 Jun 82 p 2

[Article by Sun Xiangde [1327 0686 1795], Provincial Bureau of Agriculture: "Need To Stress Product Quality in Production of Economic Crops"]

[Text] The province's production of economic crops has developed very rapidly during the past several years, the area sown to economic crops having doubled over what it had been before the Third Plenary Session of the 11th Party Central Committee. Yields per unit of area have increased for all crops, and total output has grown tremendously, oil-bearing crops increasing four fold, sugarbeets increasing 1.5 fold, flax doubling, and tobacco increasing somewhat as well. This has been of very great benefit in satisfying the needs for raw materials of light and textile industries and in increasing commune and brigade earnings. However, product quality of economic crops has risen only slowly. During the past 2 years, sugar content of sugarbeets even declined between 1.5 and 2 percent from what it had been during the 1970's, and the turn out rate for flax has stopped at its former level. Many problems also exist with quality of medicinal materials and vegetables, and because of poor quality of some products, industrial processing is difficult and businesses cannot sell them. This shows that how to improve product quality in economic crop production is a problem deserving of attention.

Aside from the effects of climatic conditions, the main reasons for the slow rise or the decline in product quality of economic crops are as follows: 1. In some economic crop producing areas, attention is given only to increasing quantity and no attention is given to increasing product quality. Some people mistakenly suppose that earnings are unaffected no matter whether quality is good or bad. 2. Poor quality resulting from lack of understanding of techniques. 3. Poor seed quality and impure varieties that produce inferior quality. 4. Some purchasing departments do not stricIty check quality of goods, and do not negotiate prices on the basis of quality. This affects the enthusiasm of the masses for improvement of quality. 5. Purchase standards for some products are not sensible. Oil-bearing crops, sugarbeets, and flax, for example, are bought by the quantity with no quality grading for purchases. In order to improve product quality, the following several tasks must be done.

Full Understanding of the Importance of Improving Product Quality.

The province has many kinds of economic crops--oil-bearing crops, hemps, sugarbeets, tobacco, and medicinal materials, all of which are raw materials for national light and textile industries. Broadly speaking, fruits, melons, flowers and such garden crops are also kinds of economic crops that are both raw materials for the food industry and are necessary consumption goods for use in the daily life of the people. Thus, the quantity of economic crops and their quality directly relates to development of the national economy and to improvement in the people's livelihood. If the province's sugarbeets average a one percent increase in sugar, without any additional facilities or investment, it is possible to increase sugar output by from 25,000 to 30,000 tons for a value of more than 30 million yuan. If flue-cured tobacco is improved by a single grade on average, peasant income increased by from 50 to 70 per mu, and increased earnings from tobacco growing areas of the province as a whole amount to between 30 and 40 million yuan. Therefore, cadres and the masses in economic crop growing areas must certainly realize the importance of improving product quality. They must particularly overcome their sole concern for quantity to the neglect of quality.

Dissemination and Improvement In Farming Techniques

It is necessary to further promote and disseminate effective conventional farming techniques and also to study and advance new techniques for improvement in product quality. For example, in field care during the present stage, in addition to doing a good job of care and of applying top dressings of phosphate and potash, it is also necessary to institute care of individual kinds of things. For example, for the sunflowers growing among oil-bearing crops, prompt removal of side branches and artificially assisted pollination must be done. Peanuts require "stripping to restrain growth of seedlings for root development" to make the most of the function of the first pair of side branches. Sugarbeets have to be thinned promptly and sugarbeet leaves retained during the growing season to increase sugarbeet photosynthesis for the accumulation of sugar. Flax requires prevention of excessive weeds from the very outset. When the flax is uprooted, all weeds must be completely removed, etc. In the case of some newly promoted techniques requiring try outs and demonstrations such as the use of plastic mulch in the growing of peanuts and tobacco, and the fertilization with trace elements and the spraying of stimulants on sugarbeets and sunflowers, fertilization and spraying should be done according to what elements the soil lacks and what the crops need.

Achieving the Sale of Clean Goods and Delivery of Clean Goods to Market

Cleaning products until they are spic and span and selling clean merchandise is one important way in which to improve product quality. When crops are harvested, the slightest bit of inattention and dirt weeds become mixed in to cause an excessive amount of detritus that impairs product quality. In Heilongjiang Province, in particular, where in the purchase of economic crops at the present stage, the naked eye is used to check and measure quality, inaccurate quality checks are very likely to occur. If clean merchandise is tendered, checking will be made easier and no major mistakes will occur, which will be an advantage for those doing the selling.

Conscientious Implementation of Purchase Policies.

When purchasing departments buy economic crop products, they should strictly understand the principle of premium price for premium quality, and conscientiously carry out purchase price and quality standards established by the state. They should widely publicize what kinds of sugarbeets will be discounted by 80 percent and what kinds will be discounted 10 or 20 percent so that the masses will have standards they can use to judge and a direction in which they can strive. Otherwise the masses will have an impression that no distinctions between good and bad are made. In addition, some product purchasing policies should be improved. An example is sugarbeets for which there are no grades for purchases, discounting being done on the basis of extranneous materials being mixed in instead of grade. This is very imprecise, and it is suggested that grade standards be reinstituted. Sugarbeets and oil-bearing crops should be graded for purchase on the basis of sugar content and oil content. When necessary, it is recommended that some quick chemical testing equipment be installed, and if tests are successful, that this method be promoted. In short, the principle of premium prices for premium quality should be genuinely put into effect and purchase policies used to give impetus to adoption of measures by the masses to improve quality of economic crop products.

MULTIPLE USES OF SOYBEANS PROMOTED

Harbin HEILONGJIANG RIBAO in Chinese 13 Jun 82 p 1

[Article: "Province Makes New Advances in Multiple Uses of Soybeans. Experts Suggest Drafting Plan With All Possible Speed for Multiple Use of Soybeans Throughout Province and Conscientious Solution to Pertinent Economic Problems"]

[Text] Progress has been fairly rapid in Heilongjiang Province's research and promotion of multiple uses for soybeans. Rignt now, two soybean protein separation workshops with daily outputs of 400 kilograms and 700 kilograms are being built, and it is anticipated that they will go into production shortly. Success has also been attained in pilot projects for the extraction of enriched protein, and experiments with adding it to several different foodstuffs have begun. During the last half of last year alone, the province produced more than 800 tons of protein of soybean origin, which was sold in Shandong, Shanxi, and Henan provinces. Definite growth has taken place in soybean protein beverages. In addition to "Jinboye," which as gone into small lot production, research has succeeded in the production of neutral protein milk and acid protein milk beverages. Bread, biscuits, sweets, and cakes to which soybean protein and phosphatide have been added are being test marketed and have been increasingly well received by the public.

At the recently convened provincial technical discussion conference on multiple uses for soybeans, experts acknowledge that multiple use of soybeans is just getting underway in Heilongjiang Province and that the potential for multiple uses of soybeans is still very great. They recommended the drafting, with all possible speed, of provincial plans for multiple use of soybeans and the conscientious solution to technical and economic policy problems in order to promote multiple uses of soybeans throughout the province.

HEILONGJIANG

PROGRESS REPORTED IN ERADICATION OF HOG CYSTICEROSIS

Success in Zhaodong County

Harbin HEILONGJIANG RIBAO in Chinese 20 Jun 82 p 1

[Text] The Zhaodong County CCP Committee and county government brought into play the functional role of the commercial, health, and animal husbandry sectors to win outstanding achievements in the eradication of cestodiasis and the elimination of cysticercosis. During the butchering of commodity hogs last year, the cull rate for "beanies" [so called because of the bean-like appearance of symptoms] was only 6.26 percent, a 3.5 percent decline from 1980. The number of "bean hogs" found during the butchering of commodity hogs between January and May this year was 230-odd fewer than for the same period last year for a more than 18,000 yuan smaller loss for the country. Zhaodong became the county in the province in which eradication of "bean hogs" had been most rapid. Not long ago it had been praised as an advanced county in the province for the eradication of cestodiasis and the elimination of cysticercosis.

Formerly this county lacked concerted and centralized leadership in the work of eradicating cestodiasis and the elimination of cysticercoisis, and it had little success. At the end of 1980, the County CCP Committee strengthened leadership of this work by setting up a coordinated leadership team for the eradication of cestodiasis and the elimination of cysticercosis, which directed attention to the work as a major task. It brought into full play the functional role of the commercial, health, and animal husbandry sectors with the result that within a short period of time, the county's work in eradicating cestodiasis and eliminating cysticercosis showed remarkable success.

One of the major actions that Zhaodong County took in the eradication of "bean hogs" was the eradication of human tapeworms [cestodiasis]. Througout the county, almost 100 buyers in food purchasing stations, a tapeworm specimen frequently in hand, would prosylitize or explain whenever they encountered people. Wherever they went, they took medicine for the eradication of tapeworms, which they gave to people to get rid of tapeworms. Ren Peifu [0117 0160 3187], buyer for the Songzhan food station eliminated 113 tapeworms in a single year and Wang Jinshan [3769 6855 1472], buyer at the Wuzhan food station eradicated 87 in a single year. They were both acclaimed by the province and county as skilled hands in the eradication of tapeworms. By way of encouraging enthusiasm for the eradication of tapeworms, the county government decided to issue a bonus of 8 yuan for the eradication of each tapeworm, also giving 2 yuan to the victim from whom the tapeworm had been eliminated. In this way, they further fanned enthusiasm for the eradication of human tapeworms. In order to eliminate "bean hogs" before butchering time, every effort was made to select out the "bean hogs" from among the more than 50,000 head annual purchased in the county at the time of purchase. In butchering hogs in urban and rural areas rigorous quarantining was done. The meat of "bean hogs" that had been quarantined was handled in accordance with national regulations.

In order to make sure that "human feces go into the toilet and hogs go into stys," so as to halt consumption of feces from humans having cestodiasis that caused the growth of larvae in hogs, management of human feces was improved. Last year the county repaired or rebuilt 83,000 pig stys and built 72,000 toilets. At the end of last December, the County CCP Committee and county government issued a document that established a policy of high compensation for contributions of manure so as to give further impetus to the raising of hogs in stys year round.

In order to reduce the number of "bean hogs" purchased by the state without creating greater economic losses for hog raisers, the county food company ran a pilot project in Xianjin and Minzhu communes on the buying of small "bean hogs," and the county government decided that this year it would undertake the purchase of "bean hogs" throughout the county to speed up making the county into a cysticercosis free one.

Commentary

Harbin HEILONGJIANG RIBAO in Chinese 20 Jun 82 p 1

[Text] Great progress has occurred during the past several years in the eradication of cestodiasis and the elimination of cysticercosis in Heilongjiang Province. The number of "bean hogs" has decreased year by year, and the cull rate for "bean hogs" at the time of commodity hog butchering has also greatly declined. Nevertheless, today the area of hog cysticerosis in the province is still very large. Survey by departments concerned shows that sufferers from cestodiasis in the province's rural villages number about 6 per 1,000 and that the national incidence is fairly high. Hog cysticerci go through a cycle of infection between humans and hogs, which seriously impairs the physical health of the people, and damages the development of live hog production. The economic losses caused in dealing in live hogs are also very great. In 1981 the province's cull rate for "bean hogs" when commodity hogs were butchered was 9.21 percent, for economic losses amounting to more than 17 million yuan. Were "bean hogs" to be eliminated, without any increase in annual livestock feed consumption there would be a 300,000 head increase in the number of commodity hogs. Therefore, every place in the province must set their sights high to do a solid job of eradicating cestodiasis and eliminating cysticercosis, striving to bring about a tremendous decline in the numbers of "bean hogs" in the province within the shortest period of time.

Though steps taken in Heilongjiang Province have not been great in the eradication of cestodiasis and the elimination of cysticercosis, some places have accumulated some rather good experiences. As a result of practice, Zhaodong

County has summarized three experiences. One is the elimination of tapeworms in humans as a means of eliminating the source of infection for "bean" growth in hogs. Second is doing a good job of pork inspections to make sure that the ailment does not enter through people's mouths. Third is toilets for people and stys for pigs, with hogs being raised in stys year round. Practice has shown that these three experiences are effective ways in which to eradicate cestodiasis and eliminate cysticercosis. The raising of live hogs in stys is a particularly good way which to put a complete stop to "bean hogs." However, at the present time, in many places in the province hogs are still not raised in stys; most roam at large. Unless this old habit is quickly changed, any thought of eradicating "bean hogs" in Heilongjiang Province will be just empty talk. With the implementation of the party's various economic policies for rural villages during the past several years, as a result of the allocation of land on which to raise fodder to the giving of grain to raise hogs and reasonable compensation being paid for the fattening of hogs, conditions are in being for the year round raising of hogs in stys. All that is needed is a strengthening of leadership and a good job of propagandizing and educating in scientific hog raising, and the year round raising of hogs in sties in rural villages is attainable.

Of course, doing a good job of eradicating cestodiasis and eliminating cysticercosis is not something that any sector can do all by itself. There has to be the kind of close coordination effected in Zhaodong County among the commercial, health, and animal husbandry sectors, bringing into full play existing technical capabilities, constantly summarizing experiences, and taking hold of the problem and holding fast to it till the end. In this way, within 3 or 4 years, there is great hope that cysticerosis can be eliminated in the province.

Zhaodong County's experiences also tell us that in undertaking the eradication of cestodiasis and the elimination of cysticercosis, efforts have to be linked to local realities, and general methods adapted to specific situations for the use of some economic methods to stir the enthusiasm of people, and to give impetus to the work of eradicating cestodiasis and eliminating cysticercosis.

Origins of 'Bean Hogs'

Harbin HEILONGJIANG RIBAO in Chinese 20 Jun 82 p 1

[Text] "Bean hogs" means hogs that have cysticercosis. The scientific name for this is echinococcosis. It is popularly termed "bean hog" or "rice grain hog" because of the pellet shape of the symptoms. Hog cysticerci are a parasite that grow in many parts of a hog's body.

When people accidentally eat "bean hog" pork, the hog cysticerci develop into tapeworms in the human digestive tract, and become parasites in the small intestines where their small rice grain size heads closely adhere to the intestinal wall, damaging the person's physical health. Mature segments of these tapeworm's bodies are continuously eliminated from the body with feces. Millions of larvae in these segments infest human feces. Should hogs eat human feces containing these larvae, they develop into cysticerci in the hog within 2 or 3 months time. Tapeworms and cysticerci carried from humans to hogs and from hogs back to humans thus infect both. People can contract not only cestodiasis but cysticercosis as well. By accidentially eating larvae on raw vegetables or from infection from a tapeworm victim, cysticerci parasites may grow in a person's muscles or body organs. If the parasites infect the eyes, blindness may result. Should they lodge in the heart or brain, one's life is in peril.

In order to guard against humans contracting tapeworms and hogs growing "beans," tapeworm parasites in human bodies have to be eradicated first to eliminate the source of infection. It is also necessary to exercise better management over pork containing cysticerci to end opportunities for people to contract tapeworms by accidentally eating pork containing cysticerci.

RURAL RESPONSIBILITY SYSTEMS WORKING IN GANZHOU PREFECTURE

Beijing RENMIN RIBAO in Chinese 29 Jul 82 p 1

[Article: "The Five Rural Occupations Flourish in Ganzhou Prefecture. All Work Rolling Along Smoothly. Tremendous Superiority of Sole Responsibility System Demonstrated. Total Grain Output Breaks 4 Billion Jin Mark for First Time. Degree of Increase Fairly Great for Sugarcane, Flue-cured Tobacco, and Watermelons"]

[Text] Following all around promotion of the responsibility system whereby households assume sole responsibility for task completion in rural Ganzhou Prefecture, Jiangxi Province, not only have the four rural occupations [farming, forestry, livestock raising, sideline occupations, and fisheries] prospered, but all work has rolled along fairly smoothly.

After the Third Plenary Session of the 11th Party Central Committee, rural Ganzhou Prefecture began to practice the system of sole responsibility for task completion, but met with obstacles. After examination of practice, its superiority became increasingly apparent and the masses demanded it more and more urgently. Leadership cadres at all levels also gradually reached a consensus with the masses, and the sole responsibility system came out of obscurity into the light, went from little use to much use, and was promoted from key points to wide areas. Last year 94 percent of production teams in the prefecture practiced assumption of sole responsibility for task completion, and 4.2 percent practiced the fixing of output quotas based on households. Consequently, the hope of breaking the 4 billion jin mark in total grain production, which had been thought about for many years, was realized for the first time. Average per capita grain production reached 537 jin, putting an end to a many year history of eating grain sold back to peasants by the state. Fairly great growth also occurred in economic crops such as sugarcane, flue-cured tobacco, and watermelons, and forestry, livestock raising, sideline occupations, and fisheries also saw new development. In 1981 per capita income for the prefecture as a whole averaged somewhat more than 120 yuan, a more than 40 yuan increase over 1980. For the first half of 1982, the rural production picture has been even better. A bumper early rice harvest is in prospect, and a greater increase than last year will occur in economic crops such as flue-cured tobacco, watermelons, and sugarcane.

Some people have said that though the assumption of sole responsibility for task completion has caused production to rise, public feeling has been dispersed and many jobs are hard to do. What are the facts? Following institution of the system of assumption of responsibility for task completion, state procurement and assigned procurement tasks have not been hard to do, but rather have been done relatively well. Last year the entire prefecture's state requisition and assigned procurement quotas for the major agricultural and sideline products of grain, oil-bearing crops and hogs were entirely fulfilled, and collective accumulations were also honored according to agreements. Households selling 10,000 jin of grain to the state numbered 274; those selling 5,000 jin numbered 1,176.

Following assignment of sole responsibility for completion of tasks, is it true that there is no way in which to undertake farmland water conservancy construction? No. Following assignment of sole responsibility for task completion, the mass of peasants have been keenly pained at waterlogging and drought disasters. They wanted to spend their own money and labor on the building of water conservancy. At the end of last year, Ganzhou Prefecture added an effectively irrigated farmland area of 21,400 mu, improved irrigation for 26,000 mu of farmland and the drainage on 2,700 mu of farmland. When construction of a large dam began in the winter of 1980 at Longshan County's biggest water conservancy project, Fengshoupo, inasmuch as 80 percent of production teams in the area that would benefit practiced assumption of sole responsibility for task completion, and since the principle of those who benefit are to be responsible was implemented, during two winters and springs, 1.4 million people worked on the project, and in March of this year the dam project was completed on schedule. Facts have shown that the following institution of the assignment of sole responsibility for task completion, water conservancy construction has been more solidly done than last year, and more attention has been paid to effectiveness.

Following practice of the assignment of sole responsibility for task completion, has the spread and popularization of science and technology been done better or worse? Contrary to what some people imagined, because the peasants have taken charge and benefits are more direct, the enthusiasm for scientific farming is even higher. Each of the communes in the 19 counties and municipalities in Ganzhou Prefecture have set up farm technology promotion and consultation stations, scientific farming demonstrations households, and households in which remuneration is linked to practice of scientific techniques. Some have also established plant protection companies and have practiced technical contracting. In rural villages an unprecedented "scientific craze" has taken place.

Following assignment of sole responsibility for task completion, rural Ganzhou Prefecture everywhere adopted a system of collective withholdings, subsidies from commune and brigade enterprises, and the pooling of funds to run schools. The school attendance rate for peasant children of school age has steadied at more than 95 percent. Some people feared that following the practice of sole responsibility for task completion, the work of recruiting soldiers would be difficult. But because of improvement in the standard of living of the masses in Ganzhou Prefecture during the last 2 years, better implementation of policies for special care to disabled servicemen and to family members of revolutionary martyrs and servicemen, and the elimination of nagging worries about the home front, quotas for the recruitment of soldiers have been over-fulfilled and both quantity and quality maintained.

Whether it will be possible following the practice of sole responsibility for task completion to do a good job of planned parenthood has become a problem that people are concerned about. Experience in Ganzhou Prefecture has shown that so long as methods are right and actions vigorous, this most difficult task can also be done well. In view of the new circumstances that have taken place following assignment of sole responsibility for task completion, this prefecture has adopted many new measures. For example, for wives who hold certificates for the birth of a single son or daughter an additional 1/10 mu of responsibility field is given, or else a special parcel of good land is assigned to encourage planned parenthood. Quite a few counties and communes also practice a planned parenthood agreement system and a planned parenthood cadre personal responsibility system to make sure of the smooth development of planned parenthood work. Last year the natural rate of population increase for the prefecture as a whole fell from 19.8 per 1,000 to 11.37 per 1,000.

ACHIEVEMENTS IN SCIENTIFIC COTTON-GROWING SKETCHED

Beijing RENMIN RIBAO in Chinese 27 Jul 82 p 2

[Article by Jiangxi Provincial CCP Committee secretary, Liu Chunxiu [0491 0193 4423]: "Lock to Science for Cotton; Depend on Science To Win High Yields"]

> [Text] Editor's Note: A look at scientific cotton farming in Jiujiang Prefecture, Jiangxi Province shows that a huge craze for the study of science is brewing in rural villages. Reliance on science to win high yields has become an inexorable trend in the development of agriculture, and it is the responsibility of leaders at all levels to give wholehearted and enthusiastic support to the demands of the masses as well as to provide careful organization and direction.

After rural villages completely establish various forms of production responsibility systems, and particularly in places practicing "double contracting" to the households [fixing output quotas on individual households with households assuming full responsibility for task completion], will it be possible to apply and spread the fruits of agricultural science and technology? In facing myriad households, how should one go about the popularization of scientific agricultural techniques? This is a problem that people are commonly concerned about at the present time. During late May and early June this year, I conducted an investigation of these problems in Jiujiang Prefecture, where I found that numerous moving examples of the broad masses of cotton growing peasants and grassroots level cadres studying science and using science, and relying on science to win high yields provided very good answers.

During the past 3 years, Jiujiang Prefecture's ginned cotton output has climbed from the 340,000 dan of 1978 to 536,000 dan in 1981, averaging a 16.7 percent increase annually. Yields per unit of area rose from 61 jin to 89 jin. Both were all-time highs. An important reason for such rapid development of cotton production in Jiujiang Prefecture during the past several years has been, the establishemnt of various forms of production responsibility systems aside, the whole-hearted support given by all levels of CCP committees and government for the urgent need of the broad masses of cadres and people to study science and use science, and the strong attention devoted to popularization of scientific farming by the myriad households.

Ever since Jiujiang Prefecture established various forms of production responsibility systems of which "centralized administration with expected output linked to individual workers" and "double contracting" to households were the dominant forms, the broad masses of cotton growing peasants realized increasingly deeply that in order to win high yields and increase their incomes fairly substantially, sole reliance on enthusiasm and hard work was far from sufficient. They would have to depend on science as well. The numbers of peasants urgently demanding a grasp of scientific cotton-growing techniques became increasingly great, creating an unprecedented atmosphere of conscious study. In order to master the fundamental knowledge about cotton production and the new cotton-growing techniques, they searched everywhere for materials, bought books and periodicals, and sought the advice of master workers. Leading comrades in the several counties I visited said, "Commune members used to dislike cadres for talking too much, but now they hope cadres will give direction. Farm technicians, in particular, are much sought after. Formerly when meetings were held, they sat in a 'cold corner' but now commune members 'pull farming into the corner.'" Once farm technicians begin to teach a class in techniques, 100 people are notified and 200 or 300 show up. Wulian Production Brigade in Furong Commune, Pengze County has 750 households. Originally the production brigade planned three runnings of a class for household heads, 250 people to a running. In the end, between 400 and 500 people showed up for the first running and the classroom could not hold them all, so a system of "issuing certificates for entry" had to be adopted. This year, Pengze County has trained a total of more than 70,000 party member, cadre, and household head attendees and has printed and distributed 150,000 copies of farm technician teaching materials. Still it has been unable to satisfy the needs of the masses. Accompanying the deepening of the mass movement to study science has been the appearance throughout the prefecture of a group of "stand out" households, one after another. At Wanhu Production Brigade in Wanhu Commune, Duchang County, female commune member Yu Caijin [0151 1752 6855] contracted last year for 2.8 mu of low cotton yeild red soil. Her husband, an accountant in a commune and brigade enterprise, had some scientific and cultural background. With the help of her husband, she voraciously studied scientific cotton growing techniques and succeeded in wresting yields of 210 jin per mu of ginned cotton from the soil. Commune members respected her scientific level of growing cotton and envied more her 1,000 yuan income. They came to her door in a steady stream to gain experience. Communes and brigades from as far away as Lin County came running to ask her to teach them her high yield experiences. In their study of science, the masses are interested in genuine results. Whenever there is some technique for increasing yields that brings quick results and that can be put to use, they act at once to use it, and are willing to make the effort and lay out the capital. This year commune members in Daqiao Commune, Ruichang County built more than 500 small boats, which they sent out on the lake to collect grass in preparation to fight drought, guard the cotton against premature deterioration, and harvest more cotton bolls in autumn. Commune members at Gangkou Commune in Jiujiang County personally bought more than 100 flatbed trucks, which they drove several tens of li to collect manure so as to provide their cottonfields with more barnyard manure. The several hundred tons of phosphate and potash that have been additionally moved into each county this year have been entirely bought up by commune members. Some have gone everywhere to buy fine varieties at a high price in a change to fine varieties. Every technique has received the serious attention of commune members everywhere. Some commune members frequently quietly observe technician and cadre experimental fields to see what new ideas they have for increased yields and what new pesticides they have to treat insect pests.

"Look to science for cotton and depend on science to win high yields" is the slogan that was raised immediately following stabilization of production responsibility systems. During the past 3 years, Jiujiang Prefecture has actively relied on farm technicians. They have devoted attention to conventional cotton-growing techniques and have promoted Pengze County's cotton-growing experiences for full stands that develop early through scientific fertilization, and have given attention to a series of cotton-growing experiences on plains areas for the prevention of disease and the elimination of insect pests. From the more than 90,000 mu of cotton in this county, yields per unit of area have risen from 61 jin in 1978 to 109 jin in 1980. Last year, in particular, more than 80 percent of the cottonfields in the county promoted the "three sprayings" (leaf surface spraying of dihydrogen phosphate, spraying of boron, and spraying of cyocel), and the "two applications" (general application of boll formation fertilizer and increased application of potash fertilizer), which are new techniques. Yields of ginned cotton per unit of area increased to 123.4 jin, making it the highest yields per unit of area county in the province. After Jiujiang Prefecture had spread Pengze County's experiences, it changed the slapdash care of cotton that had been practiced for a long period of time, and the passive situation of reduced yields resulting from disease and insect damage.

Duchang County, located in a hilly region, grew somewhat more than 100,000 mu of cotton, all of it on red soil hills. For a long time cotton yeilds have been very low. Since 1979, the Duchang County CCP Committee has earnestly summarized the lessons of experience of longterm low yields and has striven to explore the laws governing cotton growth in the hill region, coming up with a series of experiences involving "giving attention to density and earliness" (suitably close planting for increased yields from colonies) for the promotion of early ripening varieties and scientific fertilization to produce high yields. Following all around promotion of these experiences, within 3 years total output of ginned cotton has averaged annual increases of 32 percent. From the more than 1,300 mu of cotton in Wanhu Production Brigade in Wanhu Commune in this county, yields of ginned cotton per unit of area have been 151 jin, more than that of many high yield cotton growing areas on the plains. The broad masses of cadres and commune members said it well when they said: "By mastering science it has been possible to grow cotton on the low yield red soil hilly fields. No longer are their low yields one's whole life long; with fervent heart and skillful hands high yields are possible."

Right now in the rural villages a tremendous enthusiasm to study science is brewing. It is the responsibility of all us leaders at all levels to promptly, fully, and enthusiastically to lend support to the demands of the broad masses of rural cadres and people, to organize carefully, and to strengthen direction so that the movement throughout the farflung rural villages of the province to study science and use science develops widely, deeply, and continuously.

1. Need to Develop Firmly a Guiding Mentality of Reliance on Science

For many years we have relied on administrative methods to manage agriculture, and we have given little consideration to how to use economic and technical methods. The issue of agriculture's reliance on science has not received the serious attention it deserves. Serious proportional imbalance exists among the development of agricultural production and agricultural research, technical promotion, and cultural education. Following the Third Plenary Session of the 11th party Central Committee, we have had a fairly good understanding and solution of the problem of reliance on policies, and we have won many accomplishments. However, as regards the problem of reliance on science, we have to yet to devote sufficient serious attention. As the situation develops, the problem of agriculture's reliance on science becomes ever more pronounced. As a result of the longterm erroneous "leftist" influence, many comrades have a muddled mental perception. They suppose that "scientific farming and the popularization of agricultural science and technology is a matter for technical personnel"; so long as a good job is done on responsibility systems, production will rise naturally." Some even say that "with water and fertilizer to farm the fields, what need is there for technicians?" Consequently, we must constantly clear away the erroneous "leftist" influence and solve the problem of reliance on science first of all in conceptual terms. In Jiujiang Prefecture, it was only as a result of rather good solution of this problem that leaders seized the initiative in production to win a heartening situation of consecutive year increases in cotton production throughout the prefecture. Leading comrades in the Prefecture CCP Committee and government administrative offices both inspired the indoctrination of responsible comrades at all levels in a thoroughgoing understanding of the importance of studying science and using science, but also earnestly practiced what they preached, personally listening to lectures on techniques given by agricultural technicians, going into production brigades to help improve work and gain firsthand experience, and farming scientific experimental fields thereby effectively giving impetus to the launching of a campaign of studying and using science in rural villages throughout the prefecture. Statistics show that principle leaders at the prefecture and county levels farmed more than 80 mu of high yield experimental cotton fields, and that commune cadres farmed a total of 326 mu of experiemental fields.

2. Need To Establish an Agricultural Science and Technology Promotion System

Jiujiang Prefecture's economy has demonstrated that establishment from top to bottom of an agricultural science and technology promotion system is an organizational assurance for doing a good job of agricultural science and technology promotion work. Through the use of methods such as mobilization of the reutrn of people to units, fitting jobs to specialized training, and augmenting personnel, the prefecture first beefed up the county farming techniques promotion stations. At the prefecture, county, and commune levels, farming techniques promotion organizations were established, and production brigades and production teams designated one or two people responsible for farm techniques promotion work in preliminary establishment of a four level promotion network consisting of the prefecture, counties, communes, and production brigades and teams. All jurisdictions reported that the establishment of this organization and the designation of personnel played a very good role in production and that particularly after the launching of a mass movement to study science, agricultural technicians came to be generally highly regarded by organizations at all levels and were welcomed by the peasants, being frequently asked to "hold classes on techniques," "give on-site guidance," and act as "staff officers' or "advisors."

3. Need To Adopt Methods That Link Specialized Units and the Masses With the Goal of Training Double Track Technical Forces: the Existing Cadre Corps Specialized in Farming Techniques, and a Technical Corps Consisting of Millions Upon Millions of Peasants.

The peasants urgently need science yet the existing number of farm technicians is seriously inadequate. This is a problem that exists in every county. As a result, we must first rely on existing farm technicians, showing concern for them politically, supporting them in their work, and looking after their livelihood to make the most of their active guiding role in the popularization of scientific techniques. An overwhelming majority of locales have begun to give serious attention to this owrk. However, overall, still further improvements are awaited in the work of utilizing farm technical cadres and implementing policies pertaining to intellectuals. The serious lack of farm technicians in rural villages should arouse the serious attention of CCP committees and governments at all levels. Statistics show that in Jiangxi Province, there are only 1.3 farm technicians per 10,000 peasants, and for every 10,000 mu of farmland there are only 1.2 farm technicians, greatly below the national averages. Many places have reported that because of the shortage of farm technicians, good experiences cannot be summarized and new techniques cannot be spread. Consequently, we must strive on the one hand to operate well the existing agricultural institutions of higher learning and the secondary schools specializing in agriculture to train up with all possible speed the various kinds of technicians that the rural villages need. On the other hand, it is necessary to quickly train grassroots rural cadres and production hands and educated youths from among the peasantry to turn them into a major force that can be used in rural villages to promote scientific agricultural techniques, develop production, and carry forward the building of the four modernizations. This is because most of them already possess a certain cultural level, and a considerable number have rather rich practical experience in production. All that is necessary is for us to organize their training in a planned way and quite a few of them will be able very rapidly to become mainstay cadres for the promotion of agricultural technology. The problem lies in making up our minds to do it.

4. Need To Persist in Proceeding From Realities in the Promotion of Science and Technology Making Sure That Methods Are Diverse and Actions Flexible

(1) In the use of diverse forms to popularize knowledge of cotton-growing techniques, it is necessary, first of all, to run technical training classes level by level. Right now Jiujiang Prefecture is training 70-odd commune cadres, and every county has trained once all cadres above the production brigade level. The amount of training given to production team leaders and heads of household below the commune level has been even greater. Second in use of broadcasts, notices on techniques, night schools, wall newspapers, scientific and technical reports, technical advice, the printing of materials, technical discussions, and technical symposia, 10 different forms that the masses delight in hearing and seeing, to wideranginly publicize knowledge about cotton production and about new cotton growing techniques, and to summarize and exchange experiences.

(2) Establishment of scientific cotton planting "demonstration households," and "link-up households" [presumably households in which compensation is linked to output] lined to cadres staying at selected grassroots units to help improve work and gain first hand experience for guiding overall work. In Jiujiang Prefecture today, generally every production team has one or two households that are "demonstration households" for the growing of cotton and "link-up households" with links to cadres. An overwhelming majority of them are locally outstanding in production and constitute a vanguard in rural study of science, performance of scientific research, and in application and promotion of scientific techniques. The establishment of these demonstration households and link-up households has not only played an active role in the promotion of scientific production techniques in all areas by drawing on experience gained at key points, and in spreading techniques from households to villages, but has also changed cadre workstyles and cemented relations between cadres and the masses to play to a major role in giving impetus to all kinds of work in rural villages.

(3) Trial specialized technical contracting. Acting on the principle of "centralization of whatever should be centralized, and decentralization of whatever should be decentralized, and from a foundation of disease prevention and insect pest eradication for plant protection, each of the counties in Jiujiang Prefecture have done centralized monitoring of insects, centralized purchasing of pesticides, centralized formulating of pesticides, centralized direction, centralized action, and decentralized household by household use of pesticides for "five centralized and one decentralized" in active promotion of technical measures through specialized technical contracting. Last year Yongxing Commune in Yongxiu County organized a plant protection service company, which contracted disease prevention and insect pest eradication tasks for the commune's entire 5,000 mu of cotton fields. The practical result was a 44.7 percent decline in the per mu cost of pesticides, a more than 94 percent increase in effectiveness of prevention and control, and a 45 percent increase in cotton yields, which passed the 100 jin per mu mark for the first time.

Right now a mass craze for studying science, using science, and discussing science has sprung up vigorously in the farflung rural villages, and reliance on science to win high yields has become an inexorable trend in the development of agriculture. We leading comrades at all levels must courageously shoulder the heavy burden of developing agricultural production throughout the province, and make the individual contributions we should make to the modernization of agriculture.

SUMMER GRAIN PROCUREMENT INSTRUCTIONS GIVEN

Yinchuan NINGXIA RIBAO in Chinese 8 Jul 82 p 1

[Article: "Grain Departments at All Levels Called Upon To Do a Good Job in Preparing for Summer Grain Procurement and Storage; Autonomous Region Grain Bureau Holds Summer Grain State Procurement Conference"]

[Text] At the end of June, the Autonomous Region Grain Bureau convened a regionwide summer grain state procurement conference, which called upon grain departments at all levels to do a good job in the various preparations required for storage of grain and edible oils, and to assure fulfillment of this year's summer grain state procurement quotas.

The conference acknowledged that the summer grain production situation in the Yinchuan area of the region is very good. If no disasters take place, it is anticipated that a bumper grain harvest will be reaped. In accordance with state requirements and base figures set by the autonomous region for household assumption of full responsibility for task completion, each of the counties in the Yinchuan area will be able to fulfill or overfulfill this year's summer grain in terms of state procurement, purchase, and quota overfulfillment. Consequently, all city and county grain departments must make all necessary preparations to accept the grain and to cope with the high tide of summer grain going into storage.

The conference pointed out that inasmuch as more than 90 percent of rural villages in the autonomous region have instituted production responsibility systems of large-scale assignment of responsibilities, following the change from sales of grain to the state by production teams to sales to the state by individual households, the work involved in taking in grain for storage has increased tens or several tens of times. All levels of grain departments are to organize sufficient manpower and material resources, delineate areas and designate sites, forecast sales, arrange to take in all that arrives, remove all grain on the day of receipt, and complete the movement of summer grain to storage in an organized, planned, and orderly way. In addition, policies on the setting of prices on the basis of quality are to be enforced strictly, and there is to be no depreciation of quality in order to drive down prices, nor is there to be any jacking up of quality in order to raise prices. Final accounting for grain and oil purchases is to be done on the basis of specific regulations from individual county CPC committees and people's governments. Peace preservation and public security work is to be intensified to avoid accidents of various kinds.

The conference noted that in order to assure smooth completion of summer grain state purchase tasks, all jurisdictions should intensify grain market management. Any who have not fulfilled their summer grain state procurement quotas may not take summer grain to markets. Commune member households and production teams that have fulfilled or overfulfilled their summer grain state procurement quotas and who have surplus grain they want to offer for sale, may sell to granaries at negotiated prices. During the period when grain is going into storage, summer grain markets are not to be open so as to assure smooth performance of the "three summer jobs" [harvesting, planting, and field care] and overfulfillment of summer grain state procurement tasks. Commodity grain and oil can be handled only by grain departments, and other departments or units may not intervene, nor may they go into rural villages and country fair markets without authorization to purchase grain and oil. In all jursidictions, industrial and commercial administration and management, grain, public security, and transportation departments are to coordinate with each other, administer grain and oil markets, and resolutely strike down speculation and profiteering. All cases involving use of motorized vehicles in the resale of grain and oil in violation of the law shall be strictly dealt with following investigation and apprehension. Personnel who render service in the apprehension of speculators, profiteers, and those involved in the smuggling of grain and oil are to be given specific bonuses by grain departments.

The conference asked that following overfulfillment of summer grain state procurement quotas, grain departments at all levels promptly organize personnel to go into markets and into communes and brigades to actively carry out purchases of grain and oil at negotiated prices in accordance with the principle of slightly lower than the market price prevailing in areas along the way for active performance of grain and oil purchases at negotiated prices. All grassroots level granaries (or stations) are to publicize the negotiated grain purchase method and prices so that the broad masses will not worry.

ECONOMIC EFFECTIVENESS OF MECHANIZATION EMPHASIZED

Yinchuan NINGXIA RIBAO in Chinese 8 Jul 82 p 2

[Article by Feng Longjiang [7458 7893 3068]: "Take Firm Grip on Ways and Links for Improvement in Economic Effectiveness of Farm Mechanization"]

[Text] In his government work report to the Fourth National People's Conference, Comrade Zhao Ziyang pointed out that "When we think about economic problems, it is necessary to use as our point of departure improvements in economic effectiveness." Farm mechanization work is no exception. This goal is synonymous with our mechanization of agriculture.

Numerous factors enter into the economic effectiveness of farm mechanization, and ways in which to improve its economic effectiveness are also many faceted. However, many years practice have shown the crucial importance of whether or not agricultural mechanization programs are correct.

As a result of nearly 30 years of effort, our agricultural mechanization endeavors possess a fine foundation. The "Summary of the National Rural Work Conference" pointed out that "China's farmland system is complex; work forces are legion; collective economic forces are weak, and agricultural mechanization must be done selectively and step-by-step. For a considerable time in the future, mechanization, semimechanization, and use of hand tools must proceed in tandem; manpower, animal power, and electro-mechanical power used at the same time; and a combination of engineering measures and biological techniques employed at the same time. All jurisdictions should promote appropriate techniques and intensive farming on the basis of their own circumstances." This will be the program for the mechanization of China's agriculture for a fairly long time to come. It is compatible with both national circumstances and with circumstances in Ningxia Province, and is, without doubt, the agricultural mechanization program that the Ningxia Autonomous Region will follow for a fairly long time to come. Let us speak of our own region. Economic and natural conditions differ from one county and municipality (suburbs) to another. In addition, crop patterns and farming techniques are complex. There have to be priorities for agricultural mechanization, and step-by-step selective promotion of proper farm implements. In rural villages within the Huang He diversion irrigation area, economic standards are fairly high and natural conditions fairly good, so mechanization can proceed a little faster. But in the arid mountain regions, economic conditions are poor and peasant purchasing power low. There is drought with scant rain, and the heavens must be relied upon to get enough to eat, so mechanization will be slower. Even within the same prefecture and same county or municipality, inasmuch as objective conditions differ and the extent to which peasants demand mechanization differs, the speed of mechanization will differ.

At the present time the central tasks in the management of agricultural mechanization are as follows: The need to place economic effectiveness from agricultural mechanization in the paramount position, and to make a focal point of the preservation of collective property and good management and use of existing farm machinery. In addition, it is necessary to selectively promote proper use of farm machines on the basis of needs and capabilities.

We already possess a fairly impressive number of farm machines. As of the end of 1981, the autonomous region owned more than 23,500 agricultural tractors of various kinds, and farm machinery horsepower totaled 1,246,000 horsepower, accounting for 80 percent of combined machine and animal power, figuring 440,000 draft animals (converted into 330,000 horsepower). For each 10,000 mu of cultivated land, there is 375 horsepower provided by tractors. This is higher than the 360 horsepower national average. However, since these machines are scattered on communes and brigades throughout the region, and since peasant cultural and technical levels are still relatively low and differences in objective conditions fairly great from place to place, many difficulties and problems exist in the management of their use, in supply services, in technical training, in equipment maintenance and repair, in their safe use in production, in technical promotion, and in scientific research on farm mechanization. In addition, institution of diverse responsibility systems for use and management of farm machines, and development of the purchase by groups of peasant households and individual peasant households of small farm machines makes good management and use of these farm machines a very strenous task. In the course of the restructuring of the rural economy, no reduction has taken place in farm mechanization management duties; rather it has become more strenuous. Not only can it not be weakened, but rather it should continue to be strengthened. Specifically, the following is to be done:

First, continued building and perfecting farm machine use and management responsibility systems. This is a key link in the region's current farm mechanization management work. All levels of farm machine management departments should help farm machine stations (service stations), and teams further summarize experiences in the division of profits and the division of income in the responsibility system whereby anticipated output is linked to remuneration, and gradual promotion of these experiences. Good solution to existing abuses in "responsibility contracted for one thing, but no concern being shown for 100 others" (contracting of farm machines to individuals) with promotion of a contract system of "one, responsibility for fields; two, responsibility for money; three, responsibility for machine condition; and four, responsibility for safety," In production teams practicing "double contracting of responsibilities" [fixing output quotas on a household basis with peasant households assuming full responsibility for task completion], particularly in the case of large and medium farm machines under centralized collective management, effectiveness should play a role.

Second, planned readjustment and reorganization of commune farm machine stations. Where conditions permit, commune farm machine management stations may be gradually merged with farm machine stations into management and service stations to render all around services in supply, management, repair, farming on commission, training, and credit, with independent accounting and responsibility for their own profits and losses, making them play a better role.

Third, efforts to improve and intensify farm machine technical training, with gradual spread of technical training on small farm machinery to satisfy to the maximum extent possible peasant demands to learn farm machine technology. Planned rotational training of farm machine management padres at all levels, and preparing teachers for municipal and county farm machinery schools in order to create conditions for improvements in farm machine management standards and quality of technical training.

Fourth, institution of the coexistence of various forms, with collective farming predominating to bring into play the enthusiasm for mechanization of both collectives and individuals. In addition to managing and using well collectively administered farm machines, all levels of farm machine management departments should actively help the peasants manage and use farm machines that groups of households or individual households have purchased.

Fifth, strive to improve the technical state of readiness of tractors and internal combustion engines, to strengthen management of fuels, and to actively promote new techniques for saving fuels to give further impetus to fuel conservation. It is also necessary to devote further efforts to farm machine zoning work, technical promotion work, safe production, and to technical and economic research on farm mechanization.

In addition to good management and good use of exsiting farm machines, we should also realize that as a result of the implementation of rural economic policies and the institution of various production responsibility systems that have advanced agricultural production and the gradual growth of the rural economy, and have gradually increased peasant purchasing power, some suitable farm implements are required. It is suggested that departments concerned organize their production and supply, and give attention to improving their quality and to lowering their cost so as to satisfy peasant needs for smallness, goodness, and small expenditure of money.

NINGXIA

INCREASED GROWING OF SUGARBEETS REPORTED

Yinchuan NINGXIA RIBAO in Chinese 8 Jun 82 p 1

[Article: "Huang He Diversion Irrigation Area Sugarbeet Growing Area Tremendously Increased"]

[Text] Thanks to the serious attention given by all levels of leaders, this year the area planted to sugarbeets in the Huang He diversion irrigation area has increased tremendously. Incomplete statistics show a total of more than 112,000 mu sown to sugarbeets this year (more than 36,000 mu of which were intercropped), more than double last year's area.

This February the Autonomous Region Bureau of Agriculture and the Agriculture and Land Reclamation Bureau jointly convened a sugarbeet production conference to discuss and solve some problems in production and state purchases of sugarbeets. The Autonomous Region People's Government then issued "Notice on Attention to Sugarbeet Production," requiring sugarbeet producing areas to actively develop sugarbeet production. All major sugarbeet production counties (or prefectures), and state farms used various means of transmitting the spirit of the conference to the masses. By way of solving peasant difficulties in selling sugarbeets, Helan County decided to establish purchasing points in Xigang, Panchang, and Ligang communes, which relieved commune member apprehensions and resulted in the county overfulfilling its sugarbeet planting tasks. Yongning and Qingtongxia counties also convened on-site sugarbeet production conferences to which they invited old peasants and peasant technicians to impart their experiences and techniques for sugarbeet production. In order to increase sugarbeet sprouting rates, Nuang He diversion irrigation area state farms disinfected seeds with pesticides. The Yinchuan Sugar Refinery sent 51 cadres and workers to the grassroots levels to help implement plants and to set up more than 10 sugarbeet seed supply points as a convenience for the masses.

Right now the young sugarbeet seedlings are growing rather profusely. As temperatures climb, xiangjia [585E ?] and moles increase. All jurisdictions are intensifying field care and working at the prevention and control of diseases and insect pests.

WATER CONSERVANCY PROBLEMS ANALYZED

Use of Reclining Wells

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 2

[Text] In the course of struggle against drought this year, Dongdianhou Production Brigade in Longquan Commune, Mouping County built a reclining well that was 20 meters long and could raise ground water at a rate of more than 100 cubic meters per hour. It was constructed by digging a ditch to collect water in a river bed and lining it with stones. Its shape resembled a siphon layed on its side, the difference being the need for seepage. It has five advantages.

1. It collects much water and is very effective. No walls to prevent seepage are built in reclining wells, and the cross section area for seepage into the well is large. Underground water flow in the upper and lower reaches, and above ground flow in the upper reaches is able to seep into this well; thus, its capacity to intercept and collect underground flow is great. All other circumstances being equal, its ability to intercept and hold water is several times greater than any other method.

2. Construction is simple and investment is economical. Reclining wells use loose stones layed up without mortar, the stones encompassing three sides. Little money is spent and it can be built by 80 to 100 people.

3. High adaptability. All that is needed is a sandy layer and any river can be used whether, large, small, new or old. It is not affected by topography or other structures.

4. It can be transformed from a temporary project to combat drought into a permanent project for combating drought. When fighting drought, a temporary water catching ditch or pool is dug in the bottom of the river bed. If, during use, the water table drops, it may be filled with stones. Later it can be used every year for a saving in manpower required for digging, and fuel needed to pump water.

5. It saves land, does not impair the flow of floodwaters through the river bed, does not affect the farming of the fields, and the project is out of sight and not easily damaged.

The building of reclining wells is very easy. They are made of two main parts: a corridor to channel water and a verticle shaft to hold water. The corridor to channel water is the reclining part of the well. It is like the strainer in a well, i.e., the flared pipe [5363 4619] part. The function of this part is to collect underground flow. Its principal requirements are sturdiness with no collapsing or toppling, permeability to the flow of water on three sides, and allowing silt and water to enter but not allowing sand to pass. The function of the vertical water holding shaft is to connect the corridor to channel water to the ground surface so that the siphon on a water pump can go through into the corridor channel so the water can be pumped.

Centralized Management of Projects

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 2

[Text] Yanggu County has improved its ability to fight drought through the process of perfecting its production responsibility systems of double contracting [fixing output quotas on a household basis, peasant households assuming full responsibility for task completion], by giving attention to making the most of the superiority of the collective economy, through centralized management and use of large water conservancy facilities and machines, and by properly readjusting some scattered fields for which responsibility had been assigned. Despite this year's serious drought, a bumper wheat harvest was reaped from the county's 350,000 mu.

In Yanggu County, more than 90 percent of all production teams have instituted the "double contracting" production responsibility system, which has stimulated the enthusiasm for production of commune members. However, some communes and brigades divided some of their large water conservancy equipment among commune members with the result that they were unable to play their full role. Because it was difficult to use some of this equipment, it was allowed to lie idle, which hurt the "double protections" in fighting drought. Since the lunar new year, the County CCP Committee and county government have organized cadres and the masses for diligent study of the "Minutes of the National Rural Work Conference," and have helped communes and brigades to adapt general methods to specific situations to harmonize the relationship between centralization and contracting, putting under centralized management and use by production teams all large water conservancy facilities and equipment. For newly built water diversion channels, bridges, culverts, and sluice gates, pumping stations, underground conduits, and such mainstay projects, depending on the size of tasks and the size of the area receiving benefits, the production team set the amount of labor each member of the workforce had to perform, work being done on the basis of available workforces with responsibility on the basis of the number of mu served. Management and care of all water conservancy machines was the responsibility of persons specifically designated by the production team, who took care of specific machines, had specific tasks, had specific expenses, and who received specific compensation and bonuses. Watering was under the centralized direction of the production team, and vocational teams or responsibility households took turns using it. Whoever used machines was responsible for the machines. Diesel fuel expenses and maintenance and repair expenses were the responsibility of the production team. In addition, the masses were indoctrinated in an increased conception of the collective and in doing a good job of banding together for mutual help. As a result of the use of these methods, the in-service rate for pump wells throughout the county rose from the former 67 percent to 90 percent, and benefits obtained from individual wells rose from the former average 50 mu to 70 mu.

By way of adapting to large water conservancy facilities and pump well watering, this county also readjusted and merged some fields for which responsibility had been assigned that were overly scattered or exceedingly small. Before fall planting last year, a method was universally instituted to make conversions to standard mu, i.e., fields were converted to standard mu on the basis of their soil quality, soil fertility, distance from the village, production conditions, and yields over the years, and wheatfields were appropriately concentrated. Following readjustment, the county's responsibility fields declined from the former somewhat more than 70,000 plots to 4,100 plots and the water utilization rate was increased by one-third over what it had been. The wheatfields of Guodiandun Commune had been divided into 2,520 plots for the past several years, one plot in the east and another in the west. Ditches from wells had to travel around several corners before reaching the fields with very much runoff taking place along the way. Last year at fall planting time, this commune concentrated its scattered fields into square plots, reducing the number to 210, each plot divided by well defined ridges of earth. Where formerly the water recycling time had been more than half a month, it was now only 7 or 8 days. Faced with this year's severe drought, this commune made full use of the role of water conservancy facilities, the 14,000 mu of wheat in the commune receiving sufficient water on time. Yields reached 630 jin per mu, a 212 jin increase over last year.

Construction of Water Projects

Jinan DAZHONG RIBAO in Chinese 6 Jul 82 p 2

[Text] In a new situation of institution of production responsibility systems, Taian Municipality's rural villages have relied on collective strength to continue to do a good job of water conservancy construction, effectively increasing its abilities to withstand natural disasters.

Of Taian Municipality's 6,221 basic accounting units, 94.9 percent have set up "double contracting" responsibility systems linking planned output to workforces. Under these circumstances, how could the capital construction of farmland water conservancy continue? All communes and brigades used a system of several centralizations. One was adherence to centralized planning. Proceeding from the foundation of a general survey of water conservancy resources, and following the principles of adapting general methods to local situations and acting in accordance with strength and ability, they planned one by one what projects would be built at what places and at what times. Second was adherence to centralized assignment of workforces. In units practicing the linking of expected output to workforces and fixing output quotas on a household basis, production brigades and production teams took account of the workforces available in each household in planning for workers on capital construction projects and where they would be assigned in any given year. In units practicing large scale assignment of responsibilities to individual households, capital construction work was evenly spread among workforces, those exceeding quotas receiving bonuses, and those failing to complete quotas being penalized. Third was adherence to the funds and materials required by water conservancy projects that had been centrally obtained by the collective. In this way the superiority of the collective economy was brought into play, and smooth progress on all water conservancy projects was assured. After the Mujiazhuang Brigade in Zhuyang Commune instituted a responsibility system linking expected output to workforces, the collective invested 27,000 yuan in a water conservancy construction plan, bought cement, steel rods, and such materials, centralized organized workforces for work, and very rapidly built a pumping station that had a 250 meter long aqueduct and a 40 meter long stone ditch to irrigate an area of 500 mu. Along this tract of fields, not only was the wheat watered twice this year and a fine harvest won, but the spring and summer sown crops were also sown on time. After Ligu Production Brigade in Daolang Commune instituted a responsibility system of large scale assignment of responsibilities to each household, it apportioned work on capital construction on the basis of workforce strength, and provided for an 0.80 yuan payment by the collective for each additional worker supplied for capital construction, with an 0.80 yuan fine for each capital construction worker not provided. This stirred commune members enthusiasm for participation in water conservancy construction and, since last winter, commune members throughout the production brigade joining in the capital construction work have numbered 10,000. They have sunk five new pump wells and have leveled part of the land for new increase in ability to fight drought.

In the course of the water conservancy construction, the Municipal CCP Committee and municipal government provided appropriate support to those units experiencing genuine difficulties, thereby assuring a large amount of municipal water conservancy, rapid progress, and high benefits, not only completing slop protection on Shengli Reservoir, improvements to the Shengli irrigation channel, construction of the western trunk channel for Caishan Reservoir, the grouting of the Huangqian Reservoir dam, and such large and medium size project construction and equipping, but all sorts of small water conservancy projects also got under way in extremely large numbers. As of mid-June, throughout the city 345 pump wells had been newly sunk, 525 pump wells equipped, and 2,405 small wells newly sunk. A total of 1,085 projects involving the building or repair of reservoirs, pond dams, pumping stations, river diversions or spring diversions had been started, and 651 of them completed. Newly build irrigation ditches numbered 479 totaling 188 kilometers in length. The building of these projects has expanded the irrigation area by 55,000 mu and improved an irrigation area of 113,000 mu.

SHANDONG

SPECIALIZATION ENCOURAGED FOR COTTON INSECT CONTROL

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 2

[Article: "Encourage Specialized Machine Control of Insect Pests in Cottonfields"]

[Text] Insect pests persist for a long time and spread fairly quickly while cotton is growing. Left uncontrolled for a few days, they become a disaster. As a result, much manpower and intensive labor is required to control insect pests, and chances for accidental poisoning from pesticides are also fairly great.

In order to solve this problem, ever since 1979 the Provincial Farm Machinery Bureau has run pilot projects in the mechanization of cotton plant protection, principally on insect control, at seven major cotton producing counties. A look at the pilot project situation shows that the best way to do a good job of controlling insect pests of cotton and avoid the accidental poisoning of people is to institute specialized machine prevention and control in a change away from every family buying pesticides, every household storing pesticides, and every person controlling insects. Practice has demonstrated the advantages of specialized machine control of insects to be as follows: First is high labor efficiency, prompt prevention and control, and good effectiveness in killing insects. A single hanging-arm sprayer can spray 250 mu per day, and a single Taishan 18 misting machine can spray 70 mu per day, a 55 fold and a 14 fold increase in labor effectiveness respectively, as compared with hand methods of insect control. Effectiveness of prevention and control is better than hand methods. Second is a saving in labor and expense. Specialized machine control of insects results in a decline in expenses by about 20 percent as compared with hand methods, and a more than 90 percent saving in labor. Two years experience at the Laozhaozhuang Production Brigade in Laozhaozhuang Commune, Linqing County has shown that it costs between 10 and 12 yuan per mu to control insects by hand while the cost for specialized machine control of insects is 8 to 9 yuan per mu, between 2 and 3 yuan less than hand methods. Formerly this production brigade annually had more than 200 people engaged in control of cotton insects. This amounted to more than 30 percent of the brigade's total workforce. Ever since 1980, 2 hanging-arm sprayers have been used requiring only 6 fairly highly skilled operators to do this task for a saving of more than 95 percent on labor.

Third is benefits in preventing accidental poisoning of people. Control of insects using specialized machines results in a great reduction in the numbers of people coming in contact with pesticides. Furthermore, operators undergo training and possess a certain amount of plant protection knowledge and operating skill. Additionally, they are well protected, so safe production can be done.

PROVINCIAL CONFERENCE ON MOUNTAIN REGIONS HELD

Jinan DAZHONG RIBAO in Chinese 4 Jul 82 p 1

[Article: "Provincial Mountain Region Work Conference Held At Wulian. Treats Development and Building of Mountain Regions as a Strategic Task. Provincial CCP Committee and Provincial Government Comrades in Charge, Bai Rubing [4101 1172 0393], Li Zhen [2621 2182], and Zhou Zhenxing [0719 2182 5281] attend Conference"]

[Text] On 3 July, the provincial CCP Committee and provincial government convened a provincial mountain regions work conference at Wulian County. Provincial CCP Committee First Secretary Bai Rubing hosted the conference. Provincial CCP Committee secretary and Deputy Provincial Governor Li Zhen, and Deputy Provincial Governor Zhou Zhenxing, comrades in charge in all prefectures, municipalities, counties, and relevant units directly subordinate to the province, as well as representatives from some advanced communes in some mountain region communes and brigades, for a total of 264 delegates, attended the conference.

Since the Third Plenary Session of the 11th Party Central Committee, CCP committees and government at all levels in the province have diligently carried into effect a series of Central Committee programs and policies on economic construction, and in Yantai and Weifang prefectures, where conditions were fairly good to begin with, the march toward prosperity has been hastened. The four northwestern prefectures, which have long been in a backward state, have taken great strides to catch up. Although many changes have taken place in the mountain regions of south central Shandong, relatively speaking they are prefectures in which economic development is still relatively weak. In Shandong Province, mountain regions account for more than one-third of the total area. They cover a vast land area and contain a large population. Resources are abundant and the potential is very great. Most of these places are old revolutionary bases, which made a relatively great contribution during the war years, but in which the standard of living of the masses today is still relatively low. Consequently speedy transformation of the situation in mountain regions, development of the mountain region economy, and helping mountain region to become prosperous has become a decision of strategic significance in the deepgoing implementation of the party's line, programs, and policies since the Third Plenary Session, and in the further readjustment of the structure of agriculture to hasten rural economic construction. The conference acknowledged that only by doing a good job of developing and building mountain regions, and particularly doing a good job of planting trees for afforestation, could erosion be effectively prevented, the ecological balance be maintained, and all around development of economic diversification in farming, forestry, sideline occupations, and fisheries be advanced to solve the province's "hemiplegia" problem in agriculture. Building of the mountain regions relates to the overall situation of the province as a whole, and possesses major economic and political significance. Formerly construction of the mountain regions did not develop very fast in some places, and though there were many reasons for this, the main ones were slowness to understand and insufficiently vigorous action on the part of leaders. The current conference is a major step taken by the Provincial CCP Committee and the provincial government toward hastening change of the situation in mountain regions. The conference called upon relevant units throughout the province, and all levels of CCP committees and government in mountain regions, to intensify the sense of urgency and sense of responsibility about hastening mountain region construction and to make construction of mountain regions a focus of their work, to diligently summarize experiences, to rouse and lead the broad masses of cadres and people, to come to know the mountain regions, to warmly love the mountain regions, and to build the mountain regions. In the building of the mountain regions, Wulian County has done a fairly good job. They have a correct program that fits in with the spirit of the Third Plenary Session and the county's realities; they have an effective and worthwhile plan for beginning the building of the mountain regions; and they have a leadership team that struggles arduously, dares to innovate, and is united in combat. Consequently, fairly great changes have taken place in the face of the Wulian mountain region, and rather rich experiences have been accumulated about the building of mountain regions. This conference was held for the purpose of summarizing and exchanging advanced experiences from everywhere, to study and spread the experiences of Wulian County, Ying County, and other places, to increase understanding and unify mentalities, to discuss programs, policies, plans, and actions to be taken to build mountain regions, and to study how actions are to be implemented so that both agricultural production and the entire national economy in Shandong Province will be able to develop more healthily and more quickly.

On the second day of the conference, comrades in charge at Wulian County, Ying County, and Jietou Commune in Wulian County gave briefings on their experiences. Delegates to the conference made separate inspections of some advanced units in Wulian County and Ying County before the conference opened. Changes in the natural appearance of Wulian County, the fruit hanging heavy in apple orchards, and the Panshan Highway stretching in all directions in Wulian County, and the large areas of lush and rapidly growing high yield forests along the rivers of Ying County left a deep impression on them.

PROVINCE REPORTS OVERALL GRAIN SURPLUS

Chengdu SICHUAN RIBAO in Chinese 21 Jul 82 p 1

[Article: "Very Great Improvement in Province's Grain Procurement and Marketing Situation. Yet Another Major Result of the Carrying Into Effect of the Spirit of the Third Plenary Session. Virtual Balance in National Grain Income and Expenditures With Slight Surplus; Great Increase in Peasant Grain Rations With Virtual Achievement of Only Procurement From and No Sales To Any Given Production Team"]

[Text] Very great improvement has taken place in the grain procurement and marketing situation in Sichuan Province following several consecutive years of increased grain output. National grain receipts and expenditures are virtually balanced with a slight surplus; peasant grain rations have risen tremendously; and the longstanding rural problems of both grain procurement and grain sales has been solved, with virtually only procurement from and no sales to any given production team. This has been yet another major result of all of the people in the province working under the leadership of all levels of CCP committees and government conscientiously to put into effect rural economic policies and to promote production responsibility systems for vigorous development of agricultural production in the wake of the Third Plenary Session of the 11th Party Central Committee.

During the period of the 10 years of internal turmoil, the province's agricultural production sustained serious damage, and a substantial amount of state purchased grain had to be sold back to rural villages. In more than half of all production teams there was both procurement and sales, and the lives of the peasants were extremely hard. In the province's national granaries, more grain went out than came in, and grain for consumption had to be brought in from elsewhere. Following the smashing of the "gang of four," and particularly since the Third Plenary Session, under a situation of Central Committee liberalization of policies and a program of rest and recuperation, faced with extreme difficulties with grain in the province, the party and government adopted a series of economic measures. One was a reduction in state grain procurement quotas of many years standing for poverty stricken brigades in northwestern Sichuan and in some prefectures; a readjustment of state grain procurement base figures for production teams that provided fairly large amounts of commodity grain, making them procurement in excess of quotas; and arranging for reduced purchases of grain but greater sales of grain to mountain regions, to minority nationality areas, and to production teams that had been poverty stricken for a long period of time. In addition both state and excess procurement quotas were stabilized, no change guaranteed for several years. When the state needed to increase grain procurement, it held discussions with the peasants and offered preferential prices, taking the grain from communes and brigades that had increased yields or a bumper harvest.

Between 1977 and 1981, grain production increased year after year in the province. Grain output increased by 1.58 trillion jin during these 5 years for an average 3.2 billion annual increase. Such speed of development had been unprecedented since founding of the People's Republic. Rural per capita average distribution of grain rations rose from 369 jin in 1976 to 552 jin in 1981. If grain obtained from private plots and award grain sales for the sale to the state of agricultural and sideline products were added to this, the actual amount of commune member grain rations was more than 600 jin. For the overwhelming majority of peasants, the problem of sufficient food and clothing had been substantially solved. Some well-off families had a certain amount of reserves. The longstanding rural problem of both procurement and sales had been solved for the virtual realization of a situation of only procurement from but no sales to any given production team. The state's grain storage in the province also increased. In addition, as a result of purchases and sales of grain at negotiated prices and liberalization of country fair trade policies, surpluses and shortages in different places were ironed out, prices were held down, and the many needs of the masses for grain were satisfied. Rural villages had surplus grain and raising of the six livestock animals flourished with further advances taking place in market activity, which improved urban supplies of agricultural and sideline products, and grain rations for urban people were everywhere more than enough.

TITLE: "Conscientiously Perform the Work of Cost Accounting of Farm Products"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, 5 Aug 82 pp 2-4

ABSTRACT: On the basis of cost accounting statistics of 239 units, when the year 1981 is compared with that of 1980, agricultural income is increased by 8.7 percent and agricultural expenditure by 0.8 percent. The ratio of farm expenditure in farm income is reduced from 33.3 percent to 30.9 percent and the agricultural net income is raised by 12.6 percent. For every 100 yuan spent for agriculture, the net income is 224 yuan, amounting to an increase of 11.7 percent. The amount retained by the collective body is increased by 0.8 percent. The distribution to commune members is 145 yuan per person, amounting to an increase of 10 percent. Cost accounting is the basic link in improving the business management and raising the economic benefit. It forms the basis for arranging the benefits of the 3 elements of the state, the collective, and the individual member in a fair manner. Last year, in Yuanjiang County of Hunan, the yield of rape of one household was 182 jin/mu, at a cost of 46 yuan/100 jin; that of another household was 127 jin/mu, at a cost of 54 yuan/100 jin. This was due to the fact that the farmer added 5.9 man-day per mu for intensive cultivation and 60 tan of farm fertilizer. Cost accounting demonstrats the beneficial effect of the technique of the farmer to point it out as the model technique of cultivating rape next year.

TITLE: "There is a Need for Changing From Simple Grain Cropping to Multiple Products Operation"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, 5 Aug 82 pp 5-6

ABSTRACT: Some say the development of multiple products in agriculture will cause the grain acreage to shrink to result in a reduction of the quantity of grain to be purchased [by the state.] With China's one billion population, grain production is indeed extremely important. The paper claims that the goal of multiple products may be attained without sacrificing grain production by practicing the following: (1) A reasonable arrangement of grain crops and economic crops to increase the yield of both; (2) Barren mountains, grassy slopes, streams, and lakes form the country's great untapped resources for developing multi-products; (3) The development of edible oil, fruits, grass-eating animals, and aquatic products will supplement the grain requirement and change the diet habit of the people.

TITLE: "Cost Accounting is Absolutely Necessary"

SOURCE: Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, 5 Aug 82 p 29

ABSTRACT: Most recently, the national agricultural products cost accounting training course, conducted by the Ministry of Agriculture, Animal Husbandry, and Fishery, commenced for the 3rd time. The work of cost accounting for agricultural products had its beginning no earlier than 1979, when the National Agricultural Committee requested the Ministry of Agriculture to establish experimental points all over the country. Practice of these 2 years has proved that under identical conditions, the communes and brigades with cost accounting show better economic benefits than those without. Some believe that production responsibilities are now linked to individual households; cost accounting has become useless, as the household will suffer from its own wastefulness. This is a misunderstanding. The system of production responsibility does not replace cost accounting, which is to provide scientific basis and information for the use of management. When a county is to establish quotas for production, labor, cost limit, etc. it must have some indices to determine whether the stipulations of the contracts of some commune-brigades are too high or too low. In the past 2 years, there were about 7,000 test points for agricultural cost accounting, including the test points for material-expenditure. The experience may not be sufficient for it to be generally extended, but the party must include this in the daily agenda of committee work and increase the number of test points wherever the conditions permit.

SOURCE: Beijing SHUILI XUEBAO [JOURNAL OF HYDRAULIC ENGINEERING] in Chinese No 5, May 82 pp 1-10

TEXT OF ENGLISH ABSTRACT: In this paper, the influence of meteorological factors on vapotranspiration of rice field is analyzed from the point of view of the soil-plant-atmosphere continuum system in the field environment. Based upon this analysis, a mathematic model to compute evapotranspiration of rice field is established, taking into consideration such meteorological factors as the air temperature, the sunshine time, the wind velocity, and the saturation deficit. Results of the theoretical calculation is verified by experimental data of five irrigated areas of Hubei Province and the Chuxian Prefecture of Anhui Province.

SOURCE: Tianjin ZHIWU BAOHU [PLANT PROTECTION] in Chinese No 1, 1982 pp 7-9

ABSTRACT: The most frequent symptoms of yellow plant diseases are clustering of branches and leaves, small leaf size, dwarfism, atrophy and growing of foliage instead of flowers; one disease of this kind is mulberry atrophy; its pathogen was discovered in 1967 by a Japanese researcher and was found to be Mycoplasma-like organisms (MLO). Thus far, nearly 100 varieties of MLO have been discovered. In 1970s, Chinese researchers reported cases of MLO caused plant diseases; in 1978, a breakthrough was achieved in China when an international debate of more than two decades' standing concerning the pathogen of orange xanthoma was solved as being caused by Procaryofe-like organisms (PLO). In 1980, Wang Xigai (3769 2649 2818) et al. reported that the pathogen of curled leaf disease of seaweed is caused by Spironema-like organisms (SLO); this was the first time in the world that SLO had been discovered in aquatic grasses. Finally, the author stressed the isolation and culture of MLO as a major challenge facing the world today.

TITLE: "A Preliminary Report on the Reaction of Rice Varieties to the Rice Blast Physiological Races in Guangdong Province"

SOURCE: Tianjin ZHIWU BAOHU [PLANT PROTECTION] in Chinese No 2, 1982 pp 2-4

ABSTRACT: Once a rice strain with disease resistance and high yield is cultivated over a wide area, Mycorrhizae of rice blast physiological races adapted to the particular strain will multiply and spread quickly, inflicting an epidemic and crop failures. So on the one hand, selective breeding of wide spectrum disease-resistant and high-yield rice strains should be practised; on the other hand, planned rotation and cultivation of different strains can effectively prolong the number of years that these strains can be cultivated. With this purpose in mind, the author conducted a test in 1980 for determining disease resistance in rice strains projected to be propagated in Guangdong Province. A total of 30 specimens of Mycorrhizae representing eight species and 24 races were tested on various rice strains for blast physiological races. Three types of results were recorded: resistance (R), mild resistance (M) and susceptibility (S). Out of 12 rice strains tested, five strains were determined to have more than 63 percent resistance to the 30 specimens of Mycorrhizae tested. These five strains are Taokezao, Baizhenlong 410, Fubao 22, Gunongai 13, and Zhenlong 13. Included are two tables listing the disease resistance of various strains.

TITLE: "Analysis of Epidemic Factors of Late Rice Ear Blast in Hangzhou Municipality"

SOURCE: Tianjin ZHIWU BAOHU [PLANT PROTECTION] in Chinese No 2, 1982, pp 5-6

ABSTRACT: The 1980 was the year with the decade's highest epidemic damage of ear blast in late-yielding rice plantings in Hangzhou Municipality; 23 percent of the late-yielding rice cultivation was affected. However, with one-third of the area planted with late-yielding rice, hybrid nonglutinous long grain rice was generally not afflicted with the blast. The author lists four reasons for this outbreak of ear blast: (1) A limited number of strains of late-yielding rice were cultivated year after year over a wide area, thus causing the propagation of blast physiological races among Mycorrhizae. (2) Cold overcast and rainy weather by the time of the growing-ears stage further promotes the epidemic. (3) Heavy and late application of chemical nitrogen fertilizer induces the outbreak of disease. (4) Late seedling transplantation of late-yielding rice weakens the disease resistance of seedlings during rainy weather. The author advocates three measures to combat the epidemic: (1) Select more varied rice strains for cultivation to avoid concentrating on a small number of varieties. (2) Change the field microclimate in order to impede the breeding and infestation of disease germs. (3) Use pesticides to prevent and control seedling blast, ear blast, and leaf blast.

TITLE: "Discussion on Cold Damage to Paddy Rice Cultivation in Yunnan Province"

SOURCE: Kunming YUNNAN NONGYE KEJI [YUNNAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 4, 1982 pp 16-19

ABSTRACT: Given the low latitude plateau conditions of this province, generally rice yields are high and stable at elevations of about 1500 meters; yields will suffer if the elevation is 300-400 meters higher or lower. The climate is mild, generally unmarked by winter or summer but only a dry and a rainy seasons. Cold weather and rain in the rice ripening time of June through September occasionally reduce the harvest somewhat and even cause crop failures. The author suggests the selective breeding of local cold-resistant rice strains with the early sowing (in March) to utilize the warm sunny spring weather so that rice plants can grow enough heads of grain in June before the frequent rains set in. The background data came from three (1979-1981) Yunnan Province Paddy Rice Cold Damage Scientific Research Conferences.

TITLE: "Advice on Setting up Seed Banks"

SOURCE: Beijing NONGYE GONGCHENG [AGRICULTURAL ENGINEERING] in Chinese No 3, 1982 pp 20-23

ABSTRACT: In several seed banks built in China, the exterior walls were built of Number 25 red brick and plastered with Number 50 cement mortar. Chinese builders know, when the seed storeroom temperature is lower than -40°C, brick structures will fail to withstand the cold after two to three years. So after last year's completion of China's first seed bank in Guangxi, construction and operation experiences were recorded for other buildings of the same kind (in Beijing and Heilongjiang); a plan drawing is shown for a similar building in North China. These buildings are kept at -5°C and a relative humidity of 30 percent. Included are eight figures and one table, listing seed banks in Japan, Soviet Union, United States, Guangxi, and the International Rice Institute in the Philippines.

TITLE: "Vegetational Development and Climatic Changes in the Last 10,000 Years in Beijing"

SOURCE: Beijing ZHIWU XUEBAO [ACTA BOTANICA SINICA] in Chinese No 2, 1982 pp 172-181

TEXT OF ENGLISH ABSTRACT: In the previous paper, the authors discussed the vegetational and climatic changes in the past 30,000-10,000 years in Beijing. The paper is based on the information of sporo-pollen assemblages obtained from the Gaolizang, Davangzhang, Yinjiahe, Xiwuliying, and etc. with drilling cores in the vicinity of Beijing. About 12,000-10,000 years ago, deciduous broad-leaved trees were flourishing in Beijing. At that time, the climate was warm and rather wet. About 10,000-8,000 years ago, the herbaceous plants, such as artemisia, Compositae were flourishing in plain of Beijing and the mountainous region was dominant in subalpine conifer forest, consisting of Pinus, Picea, and Abies. According to the increase of needle-leaved forests at that time, we think that the climate was cooler and wetter about 9,000 B.P. In the past 8,000-6,000 years, needle-leaved and deciduous broad-leaved mixed forests, consisting of Pinus, Quercus, and Betula

[continuation of ZHIWU XUEBAO No 2, 1982 pp 172-181]

thrived under a warm and wet climate; the bogs were better developed in the plain. During 6,000-2,000 years, in a general review of the sporo-pollen assemblages of Beijing, we think that the climate was warm, especially about 5,000 years ago; the flora was mainly composed of deciduous broad-leaved trees, such as Ulmus, Quercus, Morus, and Betula. But, during 5,600 years ago or so, spruce-fir forests became predominant in the low land and the plain of Beijing again. At that time, the annual mean temperature was lower than that of the present. It corresponded to the new glacial period. The flora mainly was composed of Pinus, which had obviously been decreasing since 2,000 years. The glassland was increased in Beijing.

TITLE: "On the Effect of Different Levels of Vapor Tension on the Germination of Winter Wheat Under a Sub-optimal Temperature"

SOURCE: Shanghai ZHIWU SHENGLI XUEBAO [ACTA PHYTOPHYSIOLOGIA SINICA] in Chinese No 2, May 82 pp 115-125

TEXT OF ENGLISH ABSTRACT: The results of a study made on the effect of different levels of aqueous vapor tension as simulated solutions of mannitol in various concentrations on the germination of winter wheat under a sub-optimal temperature are as follows: (1) Moisture tensions under 15 atmospheres do not seem to have any effect on the total germination ratio. (2) When the moisture stress is increased within the range of 0-18 atmospheres there is a marked progressive decrease in the rate of water-intake, in the speed of germination, in the rate of root growth, and in the intensity of respiration, and the varietal differences become more and more remarkable. (3) The locally selected drought-resistant cultivars, as compared with those bred experimentally, have the advantages of higher respiration rate and higher germination energy and are able to maintain greater germination percentage and better root growth at a moisture stress as high as 18 atmospheres. It is suggested that in developing drought-resistant wheat varieties, such factors as moisture intake capability, germination rate and ratio, root growth and respiration intensity should be taken into consideration.

I. GENERAL INFORMATION

IMPETUS GIVEN COMMODITY GRAIN PRODUCTION

Editorial Comment

Beijing ZHONGGUO CAIMAO BAO in Chinese 29 Jul 82 p 1

[Text] Although the country's grain output has developed very greatly since founding of the People's Republic, growth in the average amount of grain per capita has not been large because of the overly fast increase in population. The conflict between supply and demand is a very prominent one. What can be done? On the basis of many years experience, genuine strengthening of the building of commodity grain production bases and efforts to raise grain production in commodity grain base counties constitutes a strategic measure for fundamental amelioration of the conflict between grain supply and demand, and it is also a major step in development of the country's agriculture toward socialization and specialization.

Division of the country's more than 2,300 county level administrative units (including some municipalities and districts subordinate to municipalities) in terms of their commodity grain production produces three broad types of regions as follows: One is the regions in which commodity grain production is fairly advanced; another is the regions in which commodity grain production is not advanced; and the third is regions totally lacking in commodity grain production. On the basis of statistics and analysis for the maximum grain output year of 1979, the basic situation of the aforestated three types of region is as follows: In the first type region are a total of 591 counties or 25 percent of the total number of county level administrative units in the country. Their grain yields average 694 jin per mu, and per capita output averages 1,077 jin. Each of these counties annually provides more than 100 million jin of state procurement or excess procurement grain, or an average of more than 200 jin per capita of state procurement or excess procurement grain for a 25.6 percent commodity rate. In the second type region are a total of 1,547 counties amounting to 65.4 percent of county level administrative units in the country. Their grain yields average 532 jin per mu; output averages 717 jin per capita; and the commodity rate is 14 percent. In the third type region are 226 counties or 9.6 percent of county level administrative units in the country. In these counties, grain yields per mu, average grain output per capita, and the commodity rate are all rather low.

The situation reported above shows that the 591 counties in the first type region are the major commodity grain production bases for the country. The commodity grain that they provide plays a decisive role in balancing grain supply and demand in the markets of the country. Generally speaking, grain production conditions in these commodity grain base counties are fairly good, and grain output, commodity rate, and the grain consumption level of the masses there are fairly high. However, if analysis is made of grain production in these counties, one can discern that the gap between one county and another is still fairly large. For example, Hanshan County in Anhui County averaged yields of 1,226 jin per mu in 1980, while in the same year in neighboring He, Wuwei, and Chao counties, which are commodity grain counties producing more than 100 million jin of state procurement and excess procurement grain for storage, yields averaged only between 750 and 760 jin per mu, a difference of more than 400 to 500 jin. In the commodity grain counties of Zhejiang Province that provided more than 100 million jin, yields averaged mostly more than 1,200 jin per mu, while in commodity grain base counties of Jiangxi Province that provided more than 100 million jin of grain, yields averaged only 700 to 800 jin per mu, a difference of between 400 and 500 jin per mu. In some commodity grain base counties in North China, in particular, grain yields per mu are very low, and the potential for increased yields is very great. On the Song Jiang and Nen Jiang plains, for example, where there are 42 counties, all but two rank as commodity grain producing basis. From a grain field area of almost 80 million mu, in 1980 yields averaged only 307 jin per mu. Were it possible to take action to increase Song Jiang and Neng Jiang plain grain yields per mu to 100 jin, within a year commodity grain output could be increased by 8 billion jin. From this may be seen that provided the grain field area of commodity grain base counties remains constant, prospects are extremely good for efforts to increase grain yields per mu, to increase total output, and to make a greater contribution to the country.

However, grain production in some commodity base counties is currently facing major problems principal of which are year by year reduction in the grain growing area and declines in yields per unit of area. This results in a drop in total grain output and corresponding reduction in state procurement and excess procurement grain sales to the state. Some commodity grain base counties have become ordinary grain production counties, and some have changed from next exporters to net importers of grain. Statistical data on 352 counties that were commodity grain counties for the 3 consecutive years 1978 to 1980 show that the area sown to grain in 1980 was 16.2 million mu less than in 1979, and further reduction occurred in 1981 as compared with 1980. In 21 counties in Hubei Province in which state procurement and excess procurement of grain for storage had been more than 100 million jin for 3 consecutive years beginning in 1978, in 1980 the grain growing area was 1.3 million mu less than in 1978. Figured on the basis of average yields per mu for these 21 counties in 1980, that amounted to a 1 billion jin decrease in grain production. In 13 counties of Jilin Province in which state procurement and excess procurement of grain for storage had been above 100 million jin for 3 consecutive years beginning in 1978, in 1980 the grain field acreage was 1.65 million mu less than in 1978. This amounted to a

600 million jin reduction in grain output. As a result of the steady decline in grain output, state and excess procurement grain quantities have correspondingly fallen.

China has a population of 1 billion, and getting enough food to eat is still a matter of major importance. As population continues to increase in future, and as people's living standards rise and production develops, the amount of grain required will increase year by year. This means that all jurisdictions will have to take grain production very very firmly in hand, and they will have to assure steady growth in grain output from commodity grain base count counties in order to expand the country's sources of grain.

Increase in grain output has many facets, and guaranteeing the necessary growing area is a fundamental condition for increased grain output. All commodity grain base counties must stabilize the existing grain growing area, and in places where conditions for the growing of grain permit, some wastelands should be developed for agriculture to expand the grain growing area, efforts made on this basis to increase yields per unit of area to assure steady growth in total grain output. In order to attain this objective, the growing area for economic crops such as cotton, oil-bearing crops, sugar crops, tobacco, jute, and ambari hemp must everywhere be layed out under the guidance of state plan with no usurpation of the grain growing area. Some commodity grain base counties in areas south of the Chang Jiang have used high yield grain fields for the growing of cotton, but yields per unit of area have not been high. They should proceed from the situation as a whole, weighing the advantages and disadvantages, the gains and the losses to make readjustments so as to take full advantage of these places for growing grain.

In some areas today, benefits from the growing of grain grows are less than from the growing of economic crops. In some high yield old commodity grain bases this problem is particularly prominent. It should be pointed out that conditions in these areas for development of grain production are far superior to those in other places. All that is required is policy guarantees of equitable economic earnings to grain growing peasants and it will be possible to advance local development of grain production. In this regard, it is necessary to readjust gradually the economic benefits derived from the growing of grain crops and economic crops, bringing them closer together to encourage peasants to strive to do a good job of grain production.

Experience has shown that in buttressing construction of commodity grain bases and developing commodity grain county grain production, it is necessary to proceed on the principle of acting within ones capabilities for a planned step by step advance. In view of the present state of the country's financial and material resources, in the short term, marching orders for the development of grain production in the 591 counties of the first type regions should be to keep high yield areas as they are, and to increase yields per unit of area in medium yield and low yield areas, with the emphasis being on medium yield areas. In the commodity grain production bases producing high yields such as the lake Tai Plain, the Chengdu Plain, the Pearl River Delta, and the Dongting Lake Plain, action should be taken to lower production costs and to increase economic benefits so that no decline will occur where yields per unit of area are already very high. In addition it is necessary to improve the low yield fields existing in these high yield areas, to increase yields per unit of area, and to assure steady growth in grain production. Medium yield commodity grain production bases such as the Boyang Lake Plain, the Jiang-Huai Plain, and the Jiang-Han Plain require vigorous efforts to raise yields per unit of area and to increase total output. In these areas, generally increased fertilization would increase grain yields, so the state should provide major support to them with funds and materials to effect fairly great development of grain production there. Suppose for a minute that for the country's 591 counties in which commodity grain production is fairly advanced that grain yields per mu could be raised from the 694 jin of 1979 to 800 jin, i.e. a 15 percent increase for a 44.8 billion jin increase in grain output. Since the grain ration level in these areas is fairly high, the commodity grain rate increase might be calculated at 60 percent, i.e. an increase of 26.9 billion jin of commodity grain. At such time, the 591 counties would be able to provide 100 billion jin of commodity grain. When newly emerging commodity grain producing areas were added to this, a rather tremendous growth would result in the quantity of the country's commodity grain production. Development of agriculture's largest and most important grain producing commodity economy would give extremely great impetus to all around development of the rural economy.

Figures for 1981

Beijing ZHONGGUO CAIMAO BAO in Chinese 29 Jul 82 p 1

[Text] Statistics from 495 commodity grain base counties show that in the 1981 grain year, state procured grain for storage amounted to about 57 percent of state procured grain for storage in the country as a whole, and played an important role in balancing national receipts and expenditures of grain for the year.

Six of the 495 aforementioned commodity grain base counties each provided more than 500 million jin of state procured grain for storage in 1981. Holding first place was Changtu County in Liaoning Province (from which 1,093,1400 jin was state procured for storage). Second was Lishu County in Jilin Province (877.33 million jin). Third was Huaide County in Jilin Province (812.82 million jin). State procurement for storage from Xinghua County in Jiangsu Province, Bayan County in Heilongjiang Province, and Yushu County in Jilin Province individually topped 500 million jin.

In terms of the agricultural population average for the province as a whole, five counties sold more than 1,000 jin per capita of state procurement and excess procurement grain in 1981. The county holding first place was Aihui County in Heilongjiang Province where grain sales to the state averaged 1,443 jin per capita.

STRENGTHENING OF RURAL ECONOMY REPORTED

Beijing BEIJING RIBAO in Chinese 17 Jul 82 p 4

[Article: "Rural Economic Strength Promotes Development of Industrial Productions; Gross Output Value of Agriculture in Recent Years Has Averaged 5.6 Percent Annual Increase; For Most Agriculture-Associated Products, Both Buying and Selling Are Vigorous"]

[Text] A new situation has occurred in the country's industrial production this year. In most cases, agriculture-associated products have shown both brisk output and sales. Some industrial plant cadres have said that for anything related to the word "agriculture," production initiative has become greater than formerly.

As of the end of June, most industrial goods using agricultural or livestock products as raw materials have increased in varying degrees throughout the country. Output of yarn, for which cotton is the major raw material, has increase 9.2 percent over the same period last year, and the output of cotton cloth has increased by 8.8 percent. Silk textiles have increased by 16.5 percent, and woolen yarn has increased by 37.3 percent. Sugar output is up by 12.6 percent, and output of cigarettes and beer has risen by 15.2 and 20.7 percent respectively. At the same time a tremendous increase has also taken place in the amount of products sold mainly to rural villages such as chemical fertilizers and farm machinery and equipment. Sales of hand tractors have increased by 40.3 percent. Total value of products such as small tractors, small horsepower diesel engines, hand operated spraying devices, rubber-tired pushcarts, and agricultural water pumps amounted to 865 million yuan for the first 5 months of this year. This represented a 42 percent increase over the same period last year, and such an amount of increase in output is a rarity.

Since the Third Plenary Session of the 11th Party Central Committee, the CCP Central Committee and the State Council have brought order out of chaos, have readjusted the proportional relationship among agriculture, light industry, and heavy industry, have adopted a series of policy measures to support and develop the rural economy, and have instituted various forms of agricultural production systems of responsibility. National gross output value from agriculture has averaged annual incremental increases of 5.6 percent for a strengthening of agriculture, the foundation of the national economy. Today, not only does agriculture provide city and town residents with copious supplies

supplies of grain, oil, meat, eggs and such agricultural and sideline products for improvement in market supply, but it directly promotes development of industrial production by producing raw materials and offering a market for sales. Major raw materials that agriculture supplies for industrial production such as grain, cotton, oil-bearing crops, milk, leather, flue-cured tobacco, silkworm cocoons, jute, and ambari hemp have increased in varying degrees during recent years. In 1981 national output of cotton totaled somewhat more than 2.96 million tons, a slightly more than one-third increase from 1978. In addition, total output of oil-bearing crops also rose from 5,218,000 tons in 1978 to somewhat more than 10.2 million tons in 1981, or almost double. In rural villages everywhere during the last 3 years, outputs of sugarcane and sugarbeets have increased 51 percent so that the sugar refining industry, which has for long lacked sufficient raw materials, is now able to steadily develop at the high speed rate of 11.7 percent annually.

Accompanying the strengthening of the rural economy has been an almost two-thirds increase within 3 years of average net earnings for peasants throughout the country. This has opened a vast market for the development of industrial production.

A comparison of the past 5 months of this year with the same period last year shows a one-third increase in sales to rural villages of small tractors, and rubber tired pushcarts, and sales of water pumps have increased 49 percent. Currently supplies of sewing machines and bicycles are tending toward saturation in cities; however, thanks to the 70 percent and somewhat more than 50 percent respective increases in quantities sold in rural villages and towns during the past 5 months, output of these two products has continued to grow by 30 to 40 percent over the same period last year.

THIRD QUARTER PEASANT FARMING NEEDS CITED

Beijing ZHONGGUO CAIMAO BAO in Chinese 27 Jul 82 p 1

[Article: "Peasants Strive to Farm Fields Scientifically and Give Attention to Sensible Use of Chemical Fertilizers and Pesticides. New Structural Changes in Supplies of Agricultural Means of Production Everywhere"]

[Text] Data provided by the Ministry of Commerce show retail sales figures for agricultural means of production of all kinds for the period January to June to have totaled 11.4 billion yuan, a 12.5 percent increase over the same period last year. This included chemical fertilizers, chemical pesticides, spraying apparatus, dusting apparatus, and plastic film for agricultural use, all of which increased over the same period last year. Despite a decline in business department sales of medium and small farm implements and draft animals from the same period last year, because of peasant purchases from country fair markets and other channels, total quantities purchased increased.

Representative sampling shows that for the first half of this year additional peasant purchases of medium and small farm implements from all channels increased by from 20 to 30 percent over the same period last year.

The peasants are striving to farm the fields scientifically, and are giving increased attention to sensible use of the means of agricultural production. During the first half of this year, everywhere new changes took place in the structure of the supply of agricultural means of production. For example, while sales of nitrogenous and phosphate fertilizer continued to rise, quantities of potash fertilizer supplied increased by 59.1 percent over the same period last year in a gradual trend toward equitability in the proportional supply of nitrogenous, phosphate, and potash fertilizers. Among pesticides, a decline also occurred in the supply of organic chlorine pesticides of high residual toxicity. Quantities supplied of various kinds of prepared pesticides containing benzene hexachloride fell by 13.8 percent from the same period last year, and supplies of prepared pesticides containing DDT fell by 14.2 percent. Meanwhile, supply of pesticides of high effectiveness and low toxicity showed remarkable increase. For example, supply of dimethoate increased 43.7 percent over the same period last year, and kitazin increased by 33.3 percent.

A person in charge at the Means of Agricultural Production Bureau of the Ministry of Commerce pointed out that the last half of the year continues to be a busy season for supply of the means of agricultural production. The amounts of commodities such as chemical fertilizers and agricultural pesticides needed for fall harvesting and winter planning will continue to increase, so supply tasks are still very heavy. Right now most sources of commodity supply are fairly ample, and needs can be satisfied under normal circumstances. However, for some varieties of fertilizer such as superior quality fertilizers, compound fertilizers, and for some pesticides such as new varieties of high effectiveness and low residual toxicity, as well as for some bamboo and wooden farm implements, and for oxen and donkeys, supplies continue to be rather tight. More planning has to be done for wood and bamboo, raw and processed materials that have been in short supply for a long time. Substitutes must also be found. Iron and plastics should be actively promoted to replace wood to bring about a new situation within a short period of time. The third quarter of the year is the season for all kinds of frequent natural disasters, so it is also necessary to give close attention to the disaster situation everywhere and to prepare materials needed to provide disaster relief.

AVERAGE PER CAPITA NET INCOME FIGURES FOR 3 CONSECUTIVE YEARS GIVEN

Beijing NONGGUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, Aug 82 p 9

[Article: "Three Consecutive Years of Tremendous Increases in Peasant Earnings"]

[Text] Survey data from the State Statistical Bureau on the earnings of 18,529 commune member families in 28 provinces, municipalities, and autonomous regions (excluding Tibet) show that since the Third Plenary Session of the 11th Party Central Committee, tremendous increase has taken place in the earnings of these commune members for 3 consecutive years, that changes have occurred in the income structure, and that peasant purchases of the agricultural means of production have increased.

According to the State Statistical Bureau survey, calculation of average per capita net income for these more than 18,000 commune member households showed a 26.60 yuan increase in 1981 over 1980, bringing net per capita income in 1981 to 233.40 yuan. The 89.90 yuan increase in earnings over the 3 year period represents a tremendous continuing increase in earnings unprecedented since the founding of the People's Republic.

Peasant household sideline occupation net earnings increased more rapidly than earnings distributed by the collective. In 1981, average annual per capita earnings of these peasant households received from the collective amounted to 116.20 yuan, a 31.3 percent increase from 1978, while net from household sideline occupations amounted to 84.50 yuan, a 1.36 fold increase.

Cash income has increased rapidly, its ratio climbing remarkably. In 1981 average per capita cash income amounted to 153.20 yuan, up 1.4 fold from 1978.

The number of households with high incomes increased, and the number of households with low incomes decreased. The number of these more than 180,000 households having average per capita net incomes of more than 300 yuan rose from 2.4 percent in 1978 to 22.6 percent in 1981. The number of households having average per capita net incomes of less than 150 yuan fell from 65 percent in 1978 to 19.7 percent in 1981.

Increase in peasant earnings has provided funds for expansion of reproduction. Private purchases by these commune member households of fixed assets of a manufactured nature amounted to 2.8 percent of net income.

REGULATIONS ISSUED ON APPROVAL PROCEDURES FOR NEW CROP VARIETIES

Beijing RENMIN RIBAO in Chinese 25 Jul 82 p 2

[Article: "Ministry of Agriculture, Animal Husbandry, and Fishery Promulgates 'National Trial Regulations for Examination and Approval of Agricultural Crop Varieties.' Accelerates Use of New Results in Breeding and Planned Promotion of Fine Varieties"]

[Text] The Ministry of Agriculture, Animal Husbandry, and Fishery has stipulated the promulgation and implementation in May this year of the "National Trial Regulations for Examination and Approval of Agricultural Crop Varieties" in order to strengthen management of agricultural crop varieties, speed up use of new results in breeding, promote fine varieties in a planned way, and advance development of agricultural production.

Excerpts of provisions contained in the trial regulations are as follows:

The country, provinces, municipalities, and autonomous regions are to establish individual crop variety examination and approval commissions. Prefectures and counties may establish crop variety examination and approval units as needed.

Farm crop variety examination and approval commissions are to be composed of representatives from agricultural administrative departments, seed promotion departments (seed stations and seed companies), agricultural research units, agricultural academies and schools, peasant breeding experts, and relevant grain, textile, and standards units.

The duties of farm crop variety examination and approval commissions will be: 1. Formulation of rules and regulations, systems, and methods pertaining to the work of farm crop variety examination and approval. 2. Examination and approval of new varieties including their economic effectiveness, area suitability, and corresponding farming techniques. 3. Leadership and organization of area experiments and production experiments for varieities. 4. To make suggestions pertaining to varieties already being promoted and about demonstration, breeding, and promotion of new varieties.

The national farm crop variety examination and approval commission is responsible for examination and approval of new varieties being given interprovince promotion. Provincial, municipal, and autonomous region examination and approval commissions are responsible for examining and approving new varieties bred by or introduced into the local province, municipality, or autonomous region.

Farm crop variety area experiments and production experiments are to be conducted on a natural area or site basis.

Varieties examined and approved by the national farm crop variety examination and approval commission are to be recommended by national area experimentation and production experimentation units responsible for them. Varieties examined and approved for promotion will be issued a variety examination and approval inspection certificate by the national farm crop variety examination and approval commission. This will be formally published by the Ministry of Agriculture, Animal Husbandry and Fishery. All new varieties examined and approved for promotion by provinces, municipalities, and autonomous regions are to be published by provincial, municipal, or autonomous region agriculture departments (or bureaus), and are to be reported as a matter of record to the national farm crop variety examination and approval commission.

When new varieties that have been examined and approved for promotion demonstrate outstanding results in increased yields in production, units or individuals that have made outstanding achievements in the breeding (or introduction of varieties), in area experiments and production experiments, and in breeding and promotion work should, on the recommendation of farm crop variety examination and approval committees to units concerned, be given bonuses.

Varieties that have not been examined and approved or whose examination and approval was turned down may not be promoted, may not be made the subject of requests for awards, and may not be publicized in periodicals or broadcasts. Those who take it upon themselves to promote varieties and cause losses in production, those who resort to deception in reporting data to higher authority, and those who steal results are to be punished according to circumstances.

WIDE PROMOTION OF NEW COTTON VARIETY REPORTED

Beijing RENMIN RIBAO in Chinese 29 Jul 82 p 3

[Article: "Large Area Promotion of 'Zhongmiansuo No 1' Cotton Begun; Breeding of New Variety To Promote Double Bumper Harvests in Grain and Cotton"]

[Text] A new variety of cotton bred by the Cotton Institute of the Chinese Academy of Agricultural Sciences, "Zhongmiansuo No 10" is a rather good breakthrough type variety that China has developed in recent years. Following several years of regional experiments, beginning this year large area promotion of it will begin in the Huang-Huai-Hai areas on a more than 400,000 mu growing area. Other cotton-growing areas of the country will also test plant it in more than 200 counties.

The Huang-Huai-Hai Plain is China's major cotton producing area, but in this area the conflict between grain and cotton for growing space is fairly pronounced. Formerly, for lack of a suitable cotton variety, more than 90 percent of cottonfields were farmed for one crop a year. When cotton was harvested, grain could not be harvested. Beginning in 1975, the Chinese Academy of Agricultural Science's Cotton Institute researchers bred new cotton varieties to solve the contest for space between grain and cotton. In 1978 breeding of cotton variety "Zhongmiansuo No 10" was finalized, cotton-growing area experiments in the Huang He basin followed for 3 consecutive years thereafter. Experts believe this variety meets requirements for bringing about a change in the farming system in the Huang-Huai-Hai region to win bumper harvests of both grain and cotton, that fiber quality is outstanding, and that both early ripening characteristics and bumper output qualities are fairly good.

"Zhongmiansuo No 10" is sown late, sprouts easily, ripens early, and has a short growing season of 113 days in its entirety, which is about 30 days shorter than for most early ripening varieties. For this reason, it can be farmed continuously with wheat or rapeseed for two crops every year. In test planting demonstrations at 22 sites in 12 counties in the 6 provinces of He'nan, Hebei, Shandong, Shanxi, Shaanxi, and Jiangsu, "Zhongmiansuo No 10" and a suitably early maturing wheat variety were paired, the cottin being sown after the wheat was harvested. Yields of ginned cotton averaged 114 jin per mu, and the previous wheat crop averaged yields of 530 jin per mu. When

"Zhongmiansuo No 10" was cropped in succession with rapeseed, yields of ginned cotton averaged 143 jin per mu, and the previous crop of rapeseed averaged yields of 208 jin per mu. In 1981, results were very good from the test planting of an area of almost 10,000 mu of "Zhongmiansuo No 10" with wheat and rapeseed as the previous crop. Following large area promotion, many communes and brigades having requisite water and fertilizer conditions can change from the growing of a single crop of cotton each year to the growing of wheat and cotton or edible-oil crops and cotton.

WILD OIL-BEARING PLANTS OF ECONOMIC IMPORTANCE IDENTIFIED

Beijing ZHONGGUO CAIMAO BAO in Chinese 31 Jul 82 p 2

[Article: "Full Use of China's Wild Oil-Bearing Crop Resources"]

[Text] China has a vast population and limited cultivated land, so despite great development of oil-bearing crop production, the average per capita supply of edible vegetable oil remains very low. The gap is very great as compared with the 30 and 40, or 40 and 50 jin in some countries. There is a fairly great shortage of the various dry vegetable oils needed in industry. How to make full use of abundant wild oil-bearing plant resources (including the as yet unused xylophytic oils) is a major topic currently requiring study.

Pertinent records show about 600 or more varieties of wild oil-bearing plants in China more than 13 million dan of which could be harvested for use to provide more than 260 million jin of fats and oil. This amounts to 80 percent of the country's industrial use of oil. A very great potential remains to be tapped. These wild oil-bearing plants contain many outstanding properties as follows:

First is high rate of oil content and great economic benefits. The seeds of the ferreous mesua [Mesua ferrea] in Yunnan and Guangxi provinces, for example, have an oil content as high as 78.99 percent, which is 9.09 percent higher than the highest oil content of English walnuts, and which is more than 20 percent higher than the world renowned oil king, the oil palm. Another example is the large-fruited hodgsonia [Hodgsonia macrocarpa] found in Yunnan and other places, whose oil content is greater than that of watermelon seeds. A single large-fruited hodgsonia tree produces between 70 and 80 jin of oil a year, more than enough for a family of several. Statistics show that wild oil-bearing plants in China with an oil content of 50 to 60 percent or more number 60 different varieties; those with an oil content of 20 percent or more number more than 300 varieties.

Second is an especially large fat and oil content and a wide range of uses such as domesticated oil-bearing crops cannot match. More than 20 species of wild oil-bearing plants such as the climbing fig, and the Chinese mosla [Mosla chinensis] contain a 50 to 60 percent linolenic acid content, which can be used in the production of paint and soap. It may also be used to replace imports of linseed oil for use in automobile industry casting technology. Some is able to prevent thrombosis, and plays a special role in the metabolism of fat in the human body. Sixteen varieties of wild oil plants including Actinodaphne acutivena and Hyoscyamus niger, which have an oleic acid content and a linolenic content of 60 to 80 percent may be widely used in the plastics industry as well as in the production of engineering plastic nylon-9 and of emulsifiers and dryers. They also are farily high in nutrients and are beneficial in medical treatment. Eighty percent of medicines used for the treatment of high blood pressure contain linolenic acid. More than 10 species of oil-bearing plants such as juansinan [4831 4828 2809] and the fruit of the cubeb litsea tree [Litsea cubeba] have a more than 60 percent lauric acid content, which is a major raw material in various chemical industries. It is also an additive for lubricants, a stabilizer in the plastics industry, and a raw material for insecticides. Wild oil-bearing plants such as guanghuaju [0342 5478 8603] and Litsaca cupeba have a capric acid content of from 50 to 70 percent and are used to make lubricants. This is a lubricant that is indispensable in space navigation launchers, and it is also a raw material for the manufacture of nylon-610 and nylon-9 fibers. Long neglected wild carrots contain petroselinic acid, which is used to increase strength and elastic in the production of stretch knitgoods.

Third is a Wide Range of Uses and Great Value for Multiple Uses. Heikenan [7810 3011 2809] and kernels of houzhang [3729 2874], for example contain large quantities of fats and oils such as lauric acid and capric acid. The fruit skins contain large amounts of stearic acid and palmitic acid, and the roots, stems, and leaves contain aromatic oils. Another example is oil from the seeds of Fumaotiebangzhui [5415 3029 6993 2761 6923], which contains many useful ingredients, and the root tubers of which may be used in medicine. It is also possible to extract tannin, white wax, starches, protein, and vitamins from the stalks and leaves of quite a few wild oil-bearing plants, deriving great economic benefit thereby.

Back in the late 1950's, Premier Zhou was extremely attentive to the development and use of wild plant resources. The "State Council Instruction on the Collection and Use of China's Wild Plant Resources," which he personally signed, noted that "full use must be made of these resources as a major supplement to light industry raw materials." Given the encouragement of this instruction, all jurisdictions and all departments did a great deal of work. The Ministry of Commerce and the Academy of Sciences organized departments concerned to carry out the country's first survey of plant resources, which discovered more than 400 different species of wild oil-bearing plants. For various reasons, particularly the damage caused by 10 years of turmoil, no specialized study was continued to thoroughly clarify the distribution, amounts, composition, properties or markets for the country's wild oil-bearing plants, to say nothing of their full use. Now it is necessary to give attention to work in the several following realms:

First, summarization of experiences and doing a good job of scientific research. Acting on relevant recommendations, in 1978 the State Scientific and Technological Commission and the Chinese Academy of Sciences made development and use of the country's wild oil-bearing plants a part of the national 1978-1985 science plan. However, for lack of specific measures and coordination with those concerned, this plan has yet to be fully implemented. It has to be made a part of the national plan, and units concerned have to be organized to do a specialized and comprehensive survey of varieties, distribution, and reserves of wild oil-bearing plants to provide a scientific basis for production and use. Right now special emphasis should go to watching the promotion to use of the results of research on major projects in major producing areas, and to solving a series of problems in production, use, introduction, and farming.

Second is reform of management methods with institution of specialized administration. There are many varieties of wild oil-bearing plants, the fatty acid content and properties of which differ. The slightest bit of mingling can impair quality benefits. Therefore, a centralized management method has to be instituted for the supply, production, and marketing of wild oil-bearing plants. In major production areas, in particular, it is necessary to begin the training of specialized personnel in a combination of management and scientific research, and to set up management organizations of different sizes to take firm hold of specimens, products, quality, prices, and markets.

Third is readjustment of commodity categories and the opening of production and marketing channels. With the development of science and technology, benefits from certain wild oil-bearing crops are greater than those of domesticated oil-bearing crops. Nevertheless, management categories continue to be for third category commodities. Sources of supply are extremely inconsistent, and production and marketing channels are not open. Industries do not dare use raw materials whose sources of supply are inconsistent, and businesses do not want to accept commodities for which no normal marketing channels exist. This seriously impairs the development and use of wild oil-bearing crops. Therefore, wild oil-bearing crops with important uses should be designated plan commodities with centralized procurement and centralized marketing or assigned quotas or fixed procurement quotas instituted to stabilize sources of supply and flow channels to create conditions for development and use.

Fourth, application of laws of value with implementation of support policies. Inasmuch as wild oil-bearing crops are widely scattered and are not easy to gather, it is necessary, first of all, to resolve the conflict between low purchase prices and the high value of daily labor so as to arouse the enthusiasm of the masses to collect them and offer them for sale. In addition to strenghtening management and administration, and the use of scientific techniques to improve utilization value, within a certain period of time support price supports should be given in the same way they are given for the support of domesticated grains and oils. For varieties of special use, a fairly high subsidy standard should be applied. Those that are able to take the place of imported oils or tung oil should be purchased at a price that is the same as the imported price or the tung oil price. For varieties for which marketing is difficult within a certain period of time but for which there are developmental prospects, taxes should be reduced or exempted in order to expand procurement and sales and to stabilize transactions.

Fifth is combining the afforestation of the motherland with a change from wild growth to domesticated growth. The State Council directive on the collection and use of China's wild plant resources pointed out that "In wilderness areas in which wild plants grow well, their economic value being greater than what would be derived from clearing of the land to grow grain, artificial culturing of wild plants should be done to make these places into major bases for the growing of wild plants." Acting under guidance of this directive, some regions in South China have introduced the planting of large amounts of cubeb litsea trees and lemongrass as well as other economic plants, which have yielded very good economic benefits. In future they will adapt general methods to local situations for the introduction of wild oil-bearing plants as a major part of economic diversification. This is being done simultaneous with afforestation and the growing of grass to make the motherland green. Many of the countries xylophytic and herbaceous oil-bearing plants are drought resistant and tolerant of windblown sand. They make fine varieties for afforestation and the growing of grass. All that is needed is planned organization and benefits can be gathered in making the motherland green, in conserving water and soil, and increasing oil-bearing plants.

We believe that only by taking a firm grip on these tasks can the country's advantages in wild oil-bearing plants be brought fully into play, and perform an active role in advancing the building of the four modernizations.

MEASURES TO ENSURE DOUBLE CROP LATE RICE HARVEST STRESSED

Brijing ZHONGGUO NOMGMIN BAO in Chinese 5 Aug 82 p 1

[Article by Commentator: "Early and Painstaking Care to Win a Bumper Double Crop Late Rice Harvest"]

[Text] South China has now entered the hectic stage of the "double rush" [rush to harvest and rush to replant]. In order to win a bumper harvest for the year as a whole, while assuring bumper output and bumper earnings from the early rice crop, and while fulfilling transplanting plans for the double season late rice, all jurisdictions should not miss the opportunity to do a good job of field care to win new breakthroughs in output of double crop late rice.

Double crop late rice is grown on one-third of the country's rice growing area and occupies an important position in total grain production. However, for many years outputs have been low and inconsistent, and during the last 2 years, as a result of damage done by the cold dew wind, yields have continued to fall greatly to the very great detriment of increases in grain production. This year a bumper early rice harvest was reaped, and in most places, the grain to be harvested in the fall is growing nicely The double crop late rice will play a decisive role in whether a bumper grain harvest for the year as a whole can be achieved and this year's increased production quotas fulfilled. This requires that all jurisdictions summarize the lessons of experience, using them as a basis for focusing on the weak links in late rice crop production and taking virorous action to tap potential for increased yields.

Following a period of effort with the implementation of planting plans for this year's double crop late rice, the growing of sturdy seedlings, the reading of materials, and the transplanting of seedlings, it seems that the situation is good overall, and that a definite basis exists for harvesting a bumper crop. However, it has to be realized that as a result of a shortage of seedlings in some places for the replanting of a large area, and as a result of delays in harvesting the early rice crop occasioned by overcast and rainy weather, flooding, and waterlogging, transplanting of the late rice crop was somewhat delayed. This has not only increased difficulties in transplanting the late rice crop, but places even higher requirements on field care from now on. Leaders at all levels should make complete appraisals and conscientiously analyze the current transplanting situation, adopt measures to hasten it, and rush "seedlings before autumn begins" [around 7 August] so that transplanting will be substantially completed by that time, and so that the number of seedlings transplanted after that time will be reduced to the minimum, thereby reducing the number of "foot dragging fields" for a balanced increase in yields.

Planting is the foundation and care is the key. For double crop late rice it is only slightly more than 3 months from transplanting to harvesting. The growing season is short; room for maneuver is slight; and natural disasters are numerous. One slip in care and the entire crop may suffer. This positively cannot be taken lightly. Conceptually and organizationally there must be adherence to unflagging efforts, guarding against and overcoming an apathetic attitude of "once transplanting has been finished, washing the feet and staying out of the fields," leading the masses in carrying forward a spirit of protracted war, promptly turning to field care, achieving care even while transplanting is being done, taking care after transplanting is finished, closing every link, giving continuous care, promoting early development and steady growth, avoiding the "cold dew wind," and achieving full heading in safety to create good conditions for consistently high yields.

Over the years a set of fairly complete scientific methods have been figured out and quite a few experiences accumulated everywhere for field care in double crop late rice production. The job now is to adapt general methods to local situations for widespread promotion of these methods and experiences in light of the characteristics of this year's double crop late rice production so that the broad masses of peasants will apply them and master them. Emphasis must be placed on doing things in their proper season and combating disasters in accordance with growth characteristics and weather conditions at different times for double crop late rice, devoting strenuous efforts to the major links of sensible follow-up fertilization, scientific use of water, prompt weeding, and prevention of diseases and insect pests.

After the hectic "double rush" season is over, the key to whether it is possible to maintain unflagging field care of double crop late rice lies in genuine strengthening of leadership. Only when leadership does not slacken efforts will the masses not take it easy. Leaders and cadres involved in the "double rush," should keep sufficient energy to continue to organize field care work, to coordinate and solve new problems in responsibility systems, to properly deploy workforces, and to assure that nothing is overlooked in farm work. Agricultural departments should do a good job of providing technical guidance for field care and in providing other services, and make full use of the role of specialized plant protection units and plant protection companies. In short, every aspect has to be fully orchestrated and matters taken firmly in hand during the 3 months of July, August, and September to win a bumper harvest from the double crop late rice.

UPDATING OF HYBRID RICE PRODUCTION FIGURES PROVIDED

Beijing ZHONGGUO NONGMIN BAO in Chinese 8 Aug 82 p 1

[Article: "China Promotes Wide Area Growing of Hybrid Rice. Spread Over 330 Million Mu In 5 Years For Yield Increases of 100 Jin Per Mu"]

[Text] The correspondent obtained the following from the national conference on exchanges of experiences on hybrid rice breeding and seed production recently held in Beijing. Since the spread over wide areas of hybrid rice in China, development has been very fast, benefits from increased yields have been high, and great achievements have been made. Between 1976 and 1981, hybrid rice spread over an accumulated 330 million mu area for overall increases in yields of about 100 jin per mu. As a result of the popularization of hybrid rice, within a single year many places changed their low yield situation. When hybrid rice has been used for late rice crop planting, in particular, results in increased yields have been most remarkable. In 1978 Zhejiang Province promoted hybrid rice for the late rice crop, and for that year late rice crop yields for the province as a whole amounted to 575 jin per mu. After Sichuan Province vigorously promoted hybrid rice, the province sustained increased rice yields for 5 years. Hybrid rice has also gradually developed and output has steadily climbed in Hunan, Jiangxi, Jiangsu, and Guangdong provinces. The situation everywhere shows that promotion of hybrid rice is a major measure for advancing the country's grain production.

This conference summarized experiences and made suggestions on problems in purification and rejuvenation of the three lines of parent pairs used in hybrid rice, and in the mongrelization and regression of seeds in seed propagation and seed production work.

EFFORTS TO SORT OUT MOUNTAINLAND RIGHTS, RESPONSIBILITIES REPORTED

Fuzhou FUJIAN RIBAO in Chinese 9 Jul 82 p 1

[Article: "Fujian Province Actively Carries out 'Three Fixeds' Work in Forestry. Fixing of Mountain Forest Rights Puts People's Minds at Ease So They Have Confidence in Developing Forestry; More Than 4,900 Units Inspected and Accepted, and 6.74 Million Mu of Privately Retained Mountains Demarcated For 860,000 Peasant Households."

[Text] Fujian Province has fixed mountain rights and forest rights, fixed the demarcation of privately retained mountains, and fixed forestry production responsibility system in the active launching of "three fixeds" work for forestry. Statistics as of the end of May 1982 show that 10,800 production brigades, state-owned forest farms and lumbering farms in the province have begun "three fixeds" work in forestry, and 9,040 units (83.4 percent of units that have begun this work) have completed field work in fixing rights for mountains and forests. More than 5,700 production brigades have fixed the demarcation of 6.73 million mu of privately retained mountains for more than 860,000 peasant households, each household getting an average 7.8 mu. More than 6,800 production brigades have preliminarily established forestry production responsibility systems for more than 51 million mu of mountain forests. "Three fixeds" work has been substantially completed, and more than 4,900 units have been inspected and accepted. This amounts to 45.5 percent of units who started it.

"Fixing of mountain forest rights puts people's minds at ease and gives them confidence about development of forestry." The "three fixeds" in forestry has further stirred mass enthusiasm for afforestation. Last winter and this spring, in addition to the afforestation done by communes and brigades collectively, various forms of afforestation such as afforestation by commune members working in partnership, individual contracting of afforestation, and afforestation of privately held mountains has taken place. Quite a large number of "standout" households who have been afforested 100 mu with 10,000 trees have appeared. This year 2.64 million mu have been afforested in the province including commune member afforestration of 460,000 mu of privately retained mountains. Qiancen Production Brigade in Huaan Country demarcated more than 1,600 mu of privately retained mountains for commune members, and this year more than 90 percent of them planted trees. This spring the production brigade planted a total of more than 210,000 China firs, each household planting an average of 839 trees. This year Guyang Production Brigade in Jinsha Commune, Minqing County afforested 940 mu including 790 mu of commune member privately retained mountains. Eleven commune member households planted 10,000 trees.

Communes and brigades that had initially established forestry production responsibility systems universally strengthened work in protecting existing mountain forests. They effectively halted reckless felling and denudation. According to statistics from Jianyang, Sanming, Jinjiang, and Putian prefectures, as a result of the checking up done on reckless felling and denudation, an additional more than 35,000 cubic meters of timber was found, and supplemental taxes and fines amounted to more than 750,000 yuan.

In the course of the "three fixeds" work in forestry, large numbers of arguments about forest rights were mediated and handled to promote stability and unity. In Shunchang County, 16 state-owned forest farms and lumbering farms have quarreled for years with communes about resources, about lumbering zones, and about mountainlands. They had many conflicts. As a result of the "three fixeds" in forestry, which fixed operating areas for state enterprises and collectives, the forestry area now administered by state-owned units has increased by 60,000 mu over what it had been. In accordance with policy regulations, when state-owned forestry units operate commune and brigade mountainlands, they must pay communes and brigades from 10 to 30 percent in forest fees. This has both consolidated state-owned units and strengthened farm and commune unity, and has promoted development of forestry production. In the course of the "three fixeds" in forestry in the province, more than 8,300 disputes about mountain forests were mediated or handled. This was 60 percent of the total number of arguments. In Jianyang Prefecture, as a result of efforts at verifying and readjusting mountains belonging to one production unit but enclosed within the boundaries of another, 80 percent of mountain forests belonging to one production unit but enclosed within the boundaries of another were readjusted. This both helped administration and management of the mountain forests, and can reduce and avoid future quarrels.

However, the "three fixeds" work in forestry developed unequally in different parts of the province. In a small number of counties and municipalities, leaders lacked understanding. They operated pilot projects without any follow up. Some simply issued a call, but did not specifically organize leadership. Work progressed slowly and many problems existed. Some did nothing but fix rights; they did not fix the demarcation of privately retained mountains or set up forestry production responsibility systems. In view of these problems, all jurisdictions are now in process of taking action, determined to work ceaselessly and unremittingly, to do well from start to finish, and to both complete and do a good job of the work of the "three fixeds" throughout the province.

HARVEST SEASON FIRE PREVENTION WORK EMPHASIZED

Lanzhou GANSU RIBAO in Chinese 10 Jul 82 p 1

[Article: "Good Job of Fire Prevention During Wheat Harvest Season. Provincial Public Security Department Issues Notice"]

[Text] The Provincial Public Security Department recently issued a notice calling upon all jurisdictions to adopt measures for doing a good job in fire prevention during the wheat harvest season.

The notice noted that during the wheat harvest season in the province last year all jurisdictions did a great amount of work, yet fire disasters continued very severe. During the wheat harvest season, 113 fire disasters occurred. Economic losses ran to 200,000 yuan, and more than 280,000 jin of grain was destroyed.

The notice said that the various forms that had come into being in various jurisdictions last year whereby "brigades fought fires in brigade threshing grounds," "households (or units) fought fires in brigade threshing grounds," or "households fought fires in household threshing grounds" had caused numerous new problems and new situations for fire prevention and management work. All jurisdictions should formulate or revise wheat threshing ground fire prevention measures in light of actual conditions this year at threshing grounds following investigation and study. They should also launch widespread and deepgoing propaganda and education in fire fighting, stir the masses to establish fire prevention rules and regulations, and institute fire prevention responsibility systems that assign responsibility to individuals. Night patrols to protect threshing grounds should be organized, a good job done of preparations to put out fires, equipment to put out fires made ready, and full use made of the role of order preservation associations and volunteer fire fighting units. Attention should be given to models and to trends. When fire disasters occur, investigation of cause should be done at once, with perpetrators being severely dealt with. Arsonists are to be resolutely attacked.

Emphasis on Prevention

Throughout the province the summer grain crop is ripening in one place after another, being harvested, and brought to the threshing grounds. A conscientious job of fire prevention safety so that the grain already in hand will escape damage and every grain of it go into storage relates directly to the personal welfare of the state, the collective and the masses of commune members. It is a matter of importance during the summer harvest season. All jurisdictions are to devote a high degree of serious attention to it, genuinely take firm hold of it and handle it well.

Summer harvest season fire prevention should emphasize prevention. A common saying goes: Prepare a house for a rainy day; preparation averts peril. A solid job of preparations for the prevention of fire has to be done in the realms of mental understanding, organizational measures, and material preparations. There have to be regular inspections and the plugging of gaps to snuff out accidents before they happen. If good prevention work is done, disastrous fires will not easily occur, and should they occur by chance, it will be possible to extinguish them at once before they lead to great losses.

When it comes to fire prevention work, most damaging of all is a supercilious and completely unconcerned paralyzed mentality, and a psychology of trusting to luck. The outbreak of disastrous fires that cause great damage may be attributed to this. Therefore, all jurisdictions should indoctrinate cadres and masses in full understanding of the danger of fire disasters and the importance of fire prevention so that every home and household is aware and women and children know to maintain a high degree of vigilance against fire disasters. In addition, it is necessary to have a strict system of rules and regulations that everyone is to obey without exception.

BRIEFS

SUMMER GRAIN PROSPECTS--Gansu Province's summer harvest is at full tide. The situation as reported from all areas shows that except for Dingxi Prefecture in Central Gansu and for the suburbs of Lanzhou, which have had reduced yields as a result of disasters, the other 10 prefectures, zhous, and municipalities will have higher outputs than last year, and in some counties summer grain production will reach an all-time high. On the basis of surveys, the Provincial Statistical Bureau has calculated a possible summer grain output totaling 5.8 billion jin, predicting an almost 10 percent increase over last year. EXHORTATION ISSUED FOR CONTINUED CARE OF THRIVING CROPS

Shijiazhuang HEBEI RIBAO in Chinese 25 Jul 82 p 1

[Article: "Go All Out to Conquer Disasters and Win a Bumper Fall Harvest"]

[Text] The arrival of summer marks the time of vigorous growth of the crops to be harvested in the fall. Full arousal of the masses for intensification of care in good time to triumph over any natural disasters that might occur in order to win a bumper autumn harvest is a task of primary urgency in rural villages for the next 3 months.

Accompanying the institution of various policies in rural villages this year, and particularly with the stabilization and improvement of various forms of responsibility systems that have brought into full play enthusiasm for collective centralized management and self-determination for the workers, the enthusiasm for socialism of the broad masses of cadres and people in Hebei Province has had an unprecedented upsurge. In addition, with the arrival of summer the rains came fairly early and the amount of rainfall was greater than for the same period last year, so the fall crops were planted on time and planted to the full, and now everything is growing rather well. The broad masses of cadres and people throughout the province should rouse their spirits, rally themselves, and work ceaselessly and unremittingly for new breakthroughs in autumn production this year to win all around bumper harvests from grain, cotton, and oil-bearing crops.

Autumn is the main season for agriculture in Hebei Province. Autumn grain output accounts for more than 70 percent of output for the year as a whole, and virtually all economic crops are harvested in autumn. Only by doing a good job of autumn production can agricultural production plans for the year as a whole be realized, only then can provisions for the livelihoods of urban and rural people be guaranteed, and only then can a greater contribution be made to the country for further development of a fine situation of unity and stability. Party and government leaders at all levels, as well as the broad masses of cadres and people, must fully realize the important economic significance and political significance of winning a bumper autumn harvest. In winning a bumper autumn harvest, one problem that merits serious attention right now is guarding against and overcoming feelings of blind optimism. The broad masses of cadres and people have to be made to realize clearheadedly that the present good growth of autumn crops is only a food foundation for harvesting a bumper crop and that 2 or 3 months remain until harvest time. If field care is not maintained, a good situation may turn into a bad one. This is also the season for numerous disasters; flooding, waterlogging and drought, as well as insect pests, hailstorms, and early frost may all occur. Anything that is not attended to may result in damage to output. So one cannot be the slightest bit smug or let down one's guard. It is necessary to do a good job of mental preparation, and material and technical preparations to meet various kinds of disasters. Reports from various places tell of great shortages of chemical fertilizer and pesticide equipment in some places. Unless ways can be found to solve these problems quickly, opportunities will be lost and reinforcements that the crops require will not be there. It is necessary to realize, as well, that though the province as a whole had a fairly good summer harvest, as a result of serious disasters original plans for increased output were not realized, and this compounds the task of increasing output from the autumn harvest. That is to say not only is it necessary to fulfill original plans for an increased autumn harvest, but many places must strive for even greater increases in autumn production, the autumn harvest making up for the summer harvest shortfalls. All this demonstrates fully that the task of reaping a bumper autumn harvest is an extremely arduous one that requires attention to guarding against and overcoming fears of difficulties. Places in which output fell substantially as a result of serious hailstorms should particularly appreciate the advantageous conditions that exist in the face of adversities, rally their spirits, build up their confidenee, and use every available means to recoup the losses occasioned by the disasters.

Reaping a bumper autumn harvest entails firm attention to the implementation of various measures to increase yields. In terms of the province as a whole, this means, first of all, firm establishment of a mentality of combat against disasters to win a bumper harvest, to triumph over the floods and waterlogging, the choking drought, the hailstorms, and the insect pests that have occurred or may occur. Herein lies the key to whether a bumper harvest may be won. Second is intensification of crop care, particularly additional fertilization given at the right times in the right amounts and using scientific methods. Insect pests have to be eliminated promptly and hoeing done to get rid of weeds. For cotton and corn, the all important autumn crops, care must be emphasized. Third is the need to take a firm grip on both grain and cotton, and to give attention as well to oil-bearing crops and other economic diversification, attention being given to timely planting of sufficient amounts of autumn vegetables in an effort to realize an all-around increase in output and earnings. Fourth is emphasis on medium yield areas where the potential for increased yields is great.

Rural leaders at all levels should place their main energies on the winning of a bumper autumn harvest and genuinely strengthen leadership. They should promptly study and solve problems in autumn production, particularly in the improvement of responsibility systems and the restructuring of grassroots level teams. They should persevere in attention to and full arousal of positive factors in all regards to do a good job of autumn production. They should take the lead in organizing large groups of cadres to go into the frontlines to assume work responsibility for specific tracts in the institution of a personal responsibility system. Scientific and technical cadres at all levels should go to the grassroots to help improve work and gain experience that can be used to improve work. They should institute responsibility systems that link output to techniques, train grassroots technical personnel, and readjust crop patterns at places so that full use is made of the role of demonstrations and scientific techniques for autumn field care to reach each and every one of the myriad households, and so that the desires of the masses to learn science and use science are satisfied.

Support from all trades and industries plays an extremely important role in winning a bumper autumn harvest. Many of the difficulties and needs currently being heard from the masses require solution by agricultural, industrial, commercial, supply and marketing, banking, and material departments. For example, the chemical fertilizers, pesticides, and small devices for the eradication of insect pests so urgently needed for autumn field care, the machines, electric power, fuels and other materials needed to combat floods and eliminate waterlogging, problems of some hardship communes, brigades, and commune members of a shortage of funds, all require the support of various trades and industries through attention to production, allocation, or supply. Consequently, all trades and industries are to give serious attention to support in winning a bumper autumn harvest as a matter of primary importance. In view of the new situation following responsibility systems, they should give prompt attention to technical guidance, make efforts to do a good job of the supply of materials such as chemical fertilizers, pesticides, pesticide machines, farm implements, electric power, and fuels, do a good job of maintenance and repair of farm equipment, and bend every effort to accomodate the masses, to insure that requirements for autumn field care and combat against disaster are met, and make a greater contribution to the building of the four modernizations.

EFFORTS FOCUSED ON KEY CROPS, GUARDING AGAINST DISASTERS

Shijiazhuang HEBEI RIBAO in Chinese 21 Jul 82 p 1

[Article: "Give Attention to Key Crop and Give Attention to Prevention of Drought and Waterlogging. Leaders at All Levels in Langfang Prefecture Go Into the Frontline of Agriculture"]

[Text] Leaders at all levels in Langfang Prefecture have gone down to the grassroots to investigate and study, to do a solid job of solving problems encountered in winning a bumper autumn harvest, to lead mass unification for struggle, to do hard work for the three months of July, August, and September, and to use every available means to win a bumper autumn harvest, resolved to recoup summer losses and realize increased production plans for the year as a whole.

As a result of a severe drought this spring such has rarely ever been encountered, Langfang's summer grain output was almost 20 percent less than last year. Immediately following the summer harvest, the Langfang Prefecture CCP Committee and government administrative offices analyzed both the favorable and unfavorable factors in winning a bumper autumn harvest. They realized the need for genuine strengthening of leadership and great exertions to bring plans for increased output to fruition. Thirteen members of standing committees and deputy assistant directors of the Prefecture CCP Committee and government administrative offices, more than 130 leadership cadres promptly went to the grassroots to investigate and study, and to discuss with the masses in common overall plans for winning a bumper fall harvest. Prefecture CCP Committee First Secretary Liu Yuansheng [0491 0955 3932] discovered in Guan County that such sandy wasteland in the county could be used. He thereupon discussed with county cadres and masses the dividing up of the sandy wasteland among commune members for farming, the commune asking little or nothing as compensation. The county then transferred more than 30,000 mu of sandy wasteland. At the meeting of County CCP Committee secretaries conference convened in June, the Prefecture CCP Committee further proposed the launching throughout the prefecture of a campaign for "full farming of fields." By dividing among commune members for farming the more than 300,000 mu of sandy wasteland, idle land, and abandoned land in the prefecture, grain output could be increased by 60 million jin. In the course of an investigation at Beiwang Commune in Langfang City, Comrade Peng Qingbin [1756 1987 1755], Prefecture CCP Committee deputy secretary, discovered that the commune centrally purchased chemical fertilizer for commune members, centrally prepared pesticides, and helped commune members sink wells thereby solving difficulties for commune members that were in urgent need of solution. He summarized this experience and recommended that not only should production brigade grassroots governments exercise two functional roles, but departments at the commune, county, and prefecture levels should fully exercise their required functional roles as well to help commune members overcome difficult ties. In the course of looking into the chemical fertilizer, phosphate fertilizer, and pesticides situations, comrades in charge at the Prefecture CCP Committee learned that during recent years some enterprises had emphasized attention to economic benefits, but their support to agricultural ideas had been weak. In view of this situation, the Prefecture CCP Committee emphasized that each enterprise was to do a good job of supporting agricultural work even while increasing economic benefits, and that they should readjust their methods of purchasing and marketing chemical fertilizer changing from marketing by enterprises themselves to business having "monopoly selling rights", the state temporarily shouldering losses with benefits going to the peasants. After this idea was made clear, a new situation came about in the production of chemical fertilizer, phosphate fertilizer, and the supply supply of other means of agricultural production.

In order to guarantee a bumper autumn harvest, this prefecture made a special point of taking a firm grip on two key measures. One was attention to key crops. Corn is a staple crop of the prefecture accounting for more than two-thirds of autumn output. All jurisdictions took firm grip on corn production so that 2.5 million mu of spring corn and more than 1.4 million mu of intermediate crop corn would grow better than in previous years. Second was strict attention to prevention of drought and waterlogging. The Prefecture CCP Committee and government administrative leaders parcelled out responsibility for sections of the river, and the County CCP Committee and county government leaders divided up responsibility for dikes. The dikes along the Yongding He, the Daqing He, and the Ziya He have already been inspected, and work is currently urgently underway on 175 drainage projects throughout the prefecture. Work will be finished before the arrival of the flood season. While working to prevent waterlogging, some communes and brigades that had had inadequate rainfall promptly carried out rush watering to replenish soil moisture.

As a result of leaders at all levels having gone down to the grass roots and having taken vigorous action, Langfang Prefecture's summer production has progressed rapidly and quality is good. As of 7 July, the 2.24 million mu that had been sown in spring had been hoed twice. This is 780,000 mu more than during the same period last year. Final thinning of late sown crops has been done on 1.1 million mu, 900,000 mu more than during the same period last year, and more than 2 million cubic meters of manure has been accumulated, 140,000 cubic meters more than last year.

FURTHER EXTENSION OF RESPONSIBILITY SYSTEMS REPORTED

Shijiazhuang HEBEI RIBAO in Chinese 28 Jul 82 p 2

[Article by Shijiazhuang Prefecture CCP Committee Office and Investigation Team, Department of Agriculture and Industry" "Responsibility System Linking Remuneration to Wheat Output Possesses Powerful Vitality"]

> [Excerpts] Editor's Note: The tremendous superiority and powerful vitality that various different forms of agriculture production responsibility systems demonstrate toward the development of agricultural production is already an incontrovertible fact. However, what is the need to practice responsibility systems linking remunerations to wheat output in high wheat producing areas? It seems people still have different perceptions of this. This survey written by the Shijiazhuang Prefecture CCP Committee Office and the Department of Agriculture and Industry provides a clear answer to this question that merits reading by everybody.
>
> At the present time, the wheat producing regions of Hebei Province are beginning work preparatory to planting wheat. It is hoped that leaders at all levels will make the summarization, promotion, and perfection of responsibility systems linking wheat output to remuneration a major part of these preparations, that they will intensify ideological indoctrination of grassroots cadres, and that they will continue to emancipate thinking so that Hebei Province's system of responsibility linking remuneration to wheat output will be steadily perfected and improved to lay a foundation for winning a bumper wheat harvest next year.

This year Shijiazhuang Prefecture has promoted a production responsibility system linking remuneration to wheat output over a wide area. Production teams practicing the linking of remuneration to production account for more than 70 percent of the total number in the prefecture. The 4.4 million mu area on which remuneration is linked to production accounts for 74 percent of the wheat growing area. What role do production responsibility systems linking wheat output to remuneration play in wheat production? Last year when crop prospects were good, when they were instituted in small areas throughout the prefecture, output increased. This year, with numerous disasters, when practiced over a large area, will they be able to increase output? Recently we conducted a survey, and practice has provided an affirmative answer.

This year wheat production in Shijiazhuang Prefecture has been beset with many calamities and numerous difficulties. First was low temperatures in early winter; second was protracted drought; third was high winds; fourth was the sudden outbreak of large numbers of wheat aphids; fifth was early arrival of hot dry winds with many occurrences; and sixth was hailstones. In short, the number and frequency of disasters were such as have not been seen in many years. However, as a result of the indomitable struggle of the people throughout the prefecture, a total of more than 2.2 billion jin of wheat was still harvested, a good harvest that was only 0.70 percent less than last year.

In this situation of numerous disasters and reduced yields, places practicing responsibility systems linking remuneration to wheat output demonstrated the outstanding superiority of the system no matter whether the size of their workforces was great or small. From the 10,243 production brigades that practiced the linking of output to remuneration before planting the wheat, results were outstanding; from the 4,600 production teams that had practiced the linking of output to remuneration for 2 years, results were even more outstanding. For those faces with the same disasters, under the same conditions those linking output to remuneration sustained a smaller decrease in output that those not practicing the linking of output to remuneration. Those who practiced the linkage early and well had increased yields, some of them tremendously increased yields. In the Dasonglou Production Brigade in Lianxing Commune, Huolu County, for example, were soil and water conservancy conditions are rather good, the continued practice this year of the contracting of jobs to be done in a certain period of time brought wheat yields of 500 jin per mu, 127 jin less than last year for a 20 percent drop. Meanwhile in the neighboring village, Xiaosonglou Production Brigade, which is a hilly region where conditions are not as good but where output quotas have been assigned to individual able-bodied laborers for 2 consecutive years, wheat yields amounted to 494 jin per mu, the same as last year. Balizhuang Production Brigade in Shulu County instituted well in advance of wheat planting the assignment of fixed output quotas to individual able-bodied laborers during the second year in which this system was used. Its wheat yields were 635 jin per mu, 183 jin more than last year and 135 jin higher than the all-time high year of 1979, at Songcao Communein Yuanshi County, seven production brigades practiced the system of large scale assignment of responsibilities, and as a result of good handling of the relationship between centralization and contracting, every brigade had increased yields. Total output for the commune as a whole was 1.05 million jin higher than last year. In Shenze County, brigades practicing the linking of remuneration to output numbered 96.7 percent the total number of brigades in the county, and total output for the county as a whole increased by more than 10 percent.

Seven out of 10 communes had increased output. Eighty-four of 123 production brigades had increased output. Of the 630 production brigades in Yuanshi County that had increased outputs, 625 practiced the linking of remuneration to output. Only five of the 58 production brigades not practicing the linking of remuneration to output had increased output. Last year wheat yields at Xianzhuang Commune in Luancheng County were 595 jin per mu. This year, when 49 of the 51 production brigades practiced the linking of remuneration to output, yields increased to 616 jin per mu, high yields becoming even higher. Throughout the prefecture many field plots had wheat yields of 1,000 jin per mu, and many households produced 10,000 jin of wheat. Survey has shown that in a year of great disasters, the linking of remuneration to wheat output stood the test and played a great role.

As a result of the survey, we learned three things as follows:

1. The linking of remuneration to wheat output holds great prospects. For many brigades, particularly high wheat yield brigades, the linking of remuneration to wheat output was done at the behest of higher authority; methods were crude; and results were unremarkable. As a result, people felt that when the "basis for high yields was good and potential small, linking of remuneration to output did not pay." In some case, remuneration was linked to output only after the wheat had been planted. There was little individual management of work procedures and results were not striking. People felt even more that "fall grain comes from good care but for wheat it is the planting that counts," and "seventy percent of the wheat harvest has to do with sprouting; there is no need for linking remuneration to expected output." Practice has shown that the linking of remuneration to wheat output is a strongly adaptable system. Low yield brigades can get high yields, and high yield brigades can get higher yields. So long as the link is formed early and well, the potential for increased yields can be tapped and retapped, and it pays very well. Furthermore, whenever collectives centralize only plowing, planting, watering, supply of chemical fertilizer and pesticides, and such work procedures, leaving to individual households the management of everything else, results are good (Naturally some work procedures require brigade assistance, as, for example harvesting and hauling of the crop, and threshing it). In some brigades in which there was little individual management of work procedures that had poor results, the main problems lay in having linked remuneration to output late and in improper handling of the relationship between centralization and contracting. Individuals did not work hard, which was not the fault of the responsibility system linking remuneration to output per se.

2. It is not difficult for individual households to farm wheat by themselves and this method helps all around performance of the "three summer jobs" [planting, harvesting, and field care]. "The linking of remuneration to wheat output is all very well and good, but there is no way to do the threshing." This year's experience further demolished this idea. So long as organizational leadership is strengthened, not only can individual household threshing be done, but three can be "one fast and two ahead of schedules," namely: fast threshing, and summer planting and summer care ahead of schedule. Because of the poor organization in some brigades threshing by

individual households takes a whole day or a half day, but when the grain is apportioned as soon as it has been threshed, the time required to clear the threshing ground is shortened and it becomes available for use in summer planting and summer care, so when all is said and done all of the "three summer jobs" are hastened along.

3. The linking of remuneration to wheat output has set the stage for the linking of remuneration to output of autumn crops. Summer has given impetus to fall for a bumper harvest for the year as a whole. The linking of remuneration to wheat output, individual farming, and the honoring of commitments has put people's minds at ease and has given them confidence to practice the linking of remuneration to output for fall crops. It has also changed the former situation of "linkage in fall but no linkage in summer." People realized that wheat and corn are akin. When dibbling corn into wheat fields they have to guard against trampling the wheat, and when they harvested the wheat, they have to guard against trampling the corn. During fall harvest there should be no delay in clearing fields to plant wheat. Thus, what worked in summer also worked in fall. What worked this year will also work next year. This is a key measure for all around sustained development of agricultural production.

RURAL ECONOMIC DIVERSIFICATION SPURRED

Shijiazhuang HEBEI RIBAO in Chinese 22 Jul 82 p 1

[Article: "Tangshan Prefecture Rural Diversification Flourishes, Leadership Organizations at All Levels Perfected; All Trades and Industries Coordinate Support"]

[Text] During this year a new situation of flourishing development has taken place in rural economic diversification in Tangshan Prefecture. As of the end of May, prefecture gross earnings from economic diversification reached 277.13 million yuan, and profits reached 176.78 million yuan, a more than 10 percent increase over the same period last year. Substantial development occured in the farming, breeding, and processing industries.

Development of rural economic diversification in Tangshan Prefecture this year was characterized in four ways as follows: One was perfection of leadership organizations, a clearcut guiding mentality, and practicality in the way work was managed. The prefecture, municipalities, and counties established economic diversification leadership teams and offices, which formed a battle front designated responsible for economic diversification. All levels formulated development plans, and the prefecture designated 10 key areas including the planting of trees for afforestation, dry and fresh fruits, silkworm cocoons, hog raising, chicken raising, rabbit raising, marten raising, lumber, light industrial foodstuffs, and freshwater breeding. Fourteen farming and breeding bases were under direct control of the prefecture. Thirty-six key communes for farming and breeding were directly controlled by municipalities and counties. Second, pertinent party policies were rather well implemented. Now 61 percent of all production brigades in the prefecture engaged in forest and fruit production practice responsibility systems. Commune and brigade enterprises practicing responsibility systems number 87 percent. Fishing industry brigades practicing responsibility systems, and particularly as a result of specialized contracting, commune and brigade enterprises have very quickly turned around a temporary decline in output. At the same time, they have vigorously supported commune member household sideline occupations. Third was the widespread application to the development of production of scientific techniques, economic effectiveness greatly increasing as a result. According to incomplete statistics, cadres and commune members who have received training in various aspects of economic diversification this year number more than 16,300, and they have played a major role in economically diversified production. Four, individual departments have supported each other in economic diversification. During the year, the Prefecture Finance Bureau allocated 1.6 million yuan of local public funds as circulating capital for support of economic diversification. The Bank of Agriculture issued economic diversification loans amounting to 43.78 million yuan, a 20.94 million yuan increase over the same period last year. Foreign trade departments have disbursed $500,000 in foreign exchange to import 1,000 tons of fish meal to support development of the marten raising and chicken raising industries. The supply and marketing system has sent 69 technical personnel to give special attention to fruit production in 131 production brigades, investing 200,000 yuan of support funds in this task.

NEW EMPHASIS GIVEN USE OF MIXED LIVESTOCK FEEDS

Accelerated Development

Harbin HEILONGJIANG RIBAO in Chinese 4 Jul 82 p 1

[Text] According to most recent statistics, the 36,000 tons of livestock feed produced during the first 5 months of this year by the province's 15 medium and small blended and mixed livestock feed processing plants have been sent in a steady stream to livestock and poultry raising farms and to households specialized in the raising of livestock everywhere in the province to provide livestock and poultry with "food" containing diverse nutrients.

During the past several years livestock feed departments in some places have begun with improvements in livestock feed processing equipment and active promotion of the use of combined livestock feeds in vigorous development of the livestock feed industry to play an active role in advancing development of the province's livestock industry. Now the cities and counties of Harbin, Qiqihaer, Mudanjiang, Jiamusi, Hegang, Shuangyashan, Yichun, Qitaihe, Shuangcheng, and Tailai have established 15 mixed and combined livestock feed processing plants of various kinds with an annual output capacity totaling 80,000 tons of livestock feed, which is 16 percent of the total amount of livestock supplied to livestock and poultry throughout the province.

Fulaerji livestock feed station in Qiqihaer renovated and improved its original livestock feed processing equipment, and in October 1981 built a mechanized production plant with a daily combined feed output of 32 tons. They went to livestock farms and to individual households specializing in the raising of livestock and poultry to investigate and understand needs. They developed Laying Hen No 4 blended feed and mixed hog feed prescriptions suited to the needs of poultry and hogs, which they actively produced and supplied to customer households causing the egg production rate to rise by 5 to 10 percent. The chickens' consumption of 8 jin per month of a single feed was cut to only 7.5 jin of blended feed for a 1/2 jin saving in the amount of feed formerly used to the delight of customer households who have increasingly turned to the buying of combined feed. The more than 1,400 tons of combined livestock feed that this plant produced between January and April this year has been completely sold.

The Shuangcheng County Livestock Feed Company has actively promoted use of combined feeds among the farflung customer households. Now more than 5,000 milk cows throughout the county are fed nothing but combined feed, and the milk production rate has increased 10 percent.

Advantages of Blended Feeds

Harbin HEILONGJIANG RIBAO in Chinese 4 Jul 82 p 1

[Text] Blended feeds are highly nutritious feeds blended from various raw materials to meet the nutritional needs of different livestock and poultry during different stages of their growth. They are selected energy feeds (corn, gaoliang, and millet), protein feeds (bean cake, fish meal, and miscellaneous crop residues), coarse green feeds (bran, and pulverized leaves, and grass), and suitable amounts of minerals (calcium, phosphorous, potash), vitamins (A,D,E, B_2, and B_{12}, niacin, and choline), amino acids (lysine, and methionine), plus antibiotics (penicillin and terramycin) as additives which are blended in machine processing into livestock and poultry feeds. Blended feeds are characterized as being finely pulverized, accurately blended, mixed evenly, and nutritionally complete.

It was formerly the practice in feeding livestock and poultry in the province to use a single variety feed. Though large amounts of grain and bean cake were used to feed livestock, the mineral, vitamin, and amino acid nutrients that poultry and livestock required were not adequately supplied. As a result the feeding cycle was long, the quantity of commodities small, grain consumption great, and the return from feed low. Under identical feeding conditions, because they meet livestock and poultry nutritional needs and have the proper amount of additives put in them, blended livestock feeds can hasten weight gain in livestock and poultry, producing more meat, eggs, and milk. They make possible a short production cycle for livestock and poultry, many commodities, small grain consumption and high return on feed. Were livestock and poultry raised everywhere in the province to be fed combined feeds, livestock and poultry output could be increased by more than 20 percent. Both livestock raising units and individuals could increase earnings, and the country could save 20 percent of its grain. This holds major significance for a change in livestock feed composition, for improving benefits from feeds, for promoting development of the livestock industry, and for increasing output while conserving grain.

'RIBAO' Commentary

Harbin HEILONGJIANG RIBAO in Chinese 4 Jul 82 p 1

[Text] The further development of the province's livestock industry has presented comrades engaged in the livestock feed industry a new problem, namely the need for vigorous development of the livestock feed industry and the use of scientific feeding methods to take the place of the former traditional and backward livestock and poultry feeding methods, the use of blended feeds to replace single feeds, shortening of the feeding cycle, lowering grain consumption, and improving economic effectiveness.

During the past several years the province's livestock feed industry has seen preliminary development; however, development has been a long way from being commensurate with present development of the livestock industry. The province's present capacity to produce blended livestock feeds accounts for only 12 percent of total livestock feed supply for the province as a whole. The province is one with rather bountiful resources, which annually has a large surplus of bran, miscellaneous crop residues, sugarbeet fibril tree leaves, grass, grit, and waste meat, blood, bones, hair, scrap fish, dregs from the manufacture of medical concoctions and such industrial and commercial leavings. These all make fine raw materials for the production of blended livestock feeds. However, formerly this large quantity of resources could not be used to the full, and some was simply wasted. Statistics show that during last year alone more than 700,000 tons of sugarbeet fibril were left in the province that were not used to make blended feeds. As a result, resources were both wasted and increase in economic effectiveness was impaired.

A major reason why the province's livestock and feed industry has developed slowly is that some comrades feel that "Heilongjiang has a lot of grain, so all that is needed is to rely on grain departments to allocate grain to develop the livestock industry." Some grain department comrades also believe that livestock feed work is not indispensable; all that is needed is a good job of grain procurement, storage, processing, transportation, and supply." Because of the existence of the various foregoing erroneous ideas, livestock feed work in many places is limited solely to how to strengthen management of livestock feed to supply a single kind of livestock feed. These comrades are unable to realize that only using the single kinds of livestock feed of the past to feed livestock and chickens is not appropriate for present day development of the livestock industry. If giving impetus to development of the province's livestock and poultry enterprises is intended, all levels of leadership units, particularly comrades engaged in grain work, will have to thoroughly do away with the old cant about livestock feed production and supply, and make full use of the province's advantages in resources. If the province's numerous bountiful resources can be fully used for development of the livestock feed industry for vigorous development of blended feeds composed of many kinds of nutrients, and scientific methods used to feed livestock and poultry, development of the livestock industry throughout the province, will inevitably be hastened, using a relatively small expenditure of livestock feed to provide the people's livelihood with more and better sources of commodities such as meat, eggs, and milk.

MULTIPLE SUCCESSES REPORTED FROM FARM MECHANIZATION PILOT PROJECTS

Nanjing XINHUA RIBAO in Chinese 3 Aug 82 p 2

[Article: "Province Achieves Success in Farm Mechanization Pilot Project Work. Future Need to Adhere to Principles of Producing What is Urgently Needed, and Impliments That Have Been Fully Tested, That Provide Marked Benefits and That the Masses Both Want and Are Able to Afford"]

[Text] Following more than 3 years of effort, Jiangsu Province's farm mechanization pilot projects have won outstanding results, providing both economic and technical benefits, and they have piled up experiences for development of the province's agricultural production and for exploration of roads to mechanization.

The province's pilot project work on farm mechanization began in 1979. As a result of efforts on the part of all concerned, the level of mechanization of individual pilot project units has been considerably improved. Today the total power used in agriculture at the province's nine pilot project units has increased by 60 percent over 1978. The amount of cultivated land per horsepower has dropped by 33.1 percent since 1978. The rate of overall farm mechanization has generally increased by from 15 to 20 percent as compared with 1978. Farm mechanization test pilot work has achieved marked success. One way has been an increase in the agricultural labor productivity rate. For the province as a whole, pilot project unit grain output per unit of labor increased by an average 30 percent in 1981 as compared with 1978. Secondly, it has promoted all around development of farming, sideline occupations, and industry. In 1981 total output value from farming, sideline occupations and industry had increased by 62 percent over 1979. Third, commune member living standards have remarkably improved. As a result of the development of farming, sideline occupations and industry in the wake of the pilot projects, commune member earnings distributions for pilot project communes and brigades in the province in 1981 were 55 percent higher than in 1978. Fourth, the contribution to the country has increased. In 1981 pilot project units sold a total of somewhat more than 440 million jin of commodity grain to the state, 16 percent more than in 1978.

During the past 3 years the province's pilot project units have introduced more than20 kinds of farm implements from inside and outside China and from inside and outside the province. Using pilot project demonstrations, they selectively promoted a sowing machine that furrows the soil and covers the seeds used in planting wheat, barley, and naked barley, a planter, a threshing machine, a ditch digging machine as several of more than 10 kinds of urgently needed machines produced. Economic benefits have been remarkable, and they have been rahter well received by the masses. More than 50,000 of the soil furrowing and seed covering machines for wheat, barley, and naked barley have now been spread throughout the province. Under the impetus provided by the pilot projects, the machine sowing of wheat, barley, and naked barley in Xuzhou Prefecture increased from 2.7 percent in 1978 to more than 60 percent.

During the past 3 years the province's farm mechanization pilot project work has had achievements and experiences; it has also learned from problems. Examples include blind pursuit of speed and norms, going in for grandiose projects, indiscriminately seeking all around mechanization, plus lack of investigation and study in work, and insufficient tailored guidance, which has lead to some farm implements not being widely promoted in the province while some implements urgently needed by the masses have not received prompt and priority testing, demonstration and promotion. A situation of not very high technical or economic benefits has arisen. At the recently convened provincewide conference on agricultural mechanization pilot project work, comrades attending diligently summarized the lessons of experiences in these regards, and, in future work, they will strive to overcome them. Only through adherence to step by step and selective development of suitable farm implements, and only through adherence to the principle of producing what is urgently needed, and producing implements that have been fully tested, that provide marked benefits, and that the masses accept and are able to afford can good rsults for small investment be achieved. At the same time, full benefits must be derived from existing farm implements and a good job of mechanized service work done so that farm mechanization will meet the new situation following promotion of agricultural production systems of responsibility. Pilor project commune and brigade farm machinery station and team farm machine service work must gradually move in the direction of specialized division of labor in service, socialization of those provided service, diversification of the items to be serviced, and businesslike administration and management.

NEED FOR INCREASED RAISING OF LEAN PORK HOGS STRESSED

Nanjing XINHUA RIBAO in Chinese 3 Aug 82 p 2

[Article: "Report on the Breeding of Lean Meat Hog Species"]

[Text] On 15 July measurements were made at the consolidated meat plant on 16 head of lean pork hogs bred by the Yangzhou Municipal Food Company Superior Variety Farm that had been slaughtered. On-site supervision and observation was done by veterinarians, technicians from all over engaged in the breeding of lean pork hog species, and cadres from the provincial food company system. What they saw was master workers practiced in hacking, chopping, slicing, and cutting use cleavers to remove the skin, and pointed knives to debone. In the twinkling of an eye, the fat and the skin was placed on one side, and the shoulders, forelegs, back and rear legs containing lean meat were layed out in an orderly fashion on the other. Then the director of the Jaingsu Academy's Dissection Teaching and Research Unit, Lu Tong [7120 2717], zestfully described for everyone the component muscles in each part.

Difficulty Marketing Hog Fat, Lard, and Pigskin

The Yangzhou Municipal Food Company deputy manager, Zhu Chun [4281 5028] had some other thoughts on his mind. He said, "Nowadays customers come to food markets carrying baskets and walking here and there. When they see very fatty pork, they just gape at it. The business people look at the fat they cannot sell and feel blue. After they have been supplied with cuts of pork, the price for lean pork goes up yet there is never enough to sell. The price for fat and lard tumbles, yet they cannot be sold. Consumers want lean pork, and we businessmen also demand hogs with more lean pork! Recently the Cuiyuanqiao food market in Yangzhou has had five head of hogs delivered daily, and everyday about 200 jin of fat cannot be sold. Because more and more poeple do not eat fat pork, between January and May last year the Yangzhou markets had no choice but to render 79 tons of fat into lard, and during the same period this year, this amount climbed to 1,081 tons. During the slightly more than a month since June, another 500 tons has been rendered into lard. The food company's lard bulges from warehouses and there are even 220,000 jin of leaf lard on hand. Pastry producers and eating houses have taken all the lard they can use. Nowadays pure vegetable oil pastries are all the rage, and year after year bumper crops of rapeseeds are harvested. Sales of rapeseed oil to one food plant by the grain department amounted to 90,000 jin at parity price, and this crippled the market for lard. Still another change that has taken place is the difficulty in selling pigskin. Formerly some tanneries sent people to meat products plants to help remove the skin. Now, some remove the skin carefully and send it to tanneries, but they do not want it.

Increasing the Lean Pork Rate Can Be Done

The breeding of lean pork hog species is not only an urgent task, but a way already exists to do it. The Yangzhou Municipal Food Company's Superior Breeds Farm has done some experimental breeding, and has made measurements of four slaughterings. This was the fifth one, and the lean pork rate was a general 50 percent of so, more than 10 percent higher than the lean pork rate for most live hogs. Yang Qing'an [2799 3237 1344], doctor of veterinary medicine from the Provincial Food Company who personally participated in the breeding experiments, said that beginning since the end of 1978 the province has carried out experiments in the breeding of lean pork hog species at 10 sites including Shazhou, Nanjing, Yangzhou, Dongtai, Haimen, and Taixian, and that the lean pork rate has been stabilized at around 50 percent. Methods and means of achieving this have been worked out.

Provincial Science Commission agronomist, Comrade Zhang Chongying [1728 1504 5391] and others gave a brief and to the point explanation of the various techniques used in the province for the breeding of lean meat hog species. First has been the importation of lean prok boars for use as studs including Landraces (from Denmark), Yorkshires (from the United Kingdom), and Durocs (from the United States) for mating with local superior breed sows from Jiangsu Province, carrying out binary or ternary crossing. In order to make the most of the role of stud boars, the artificial insemination methods used by many superior variety farms may be used, the semen being delivered to where it is needed to hasten the spread of lean pork hog varieties. Second has been an increase in protein feed, particularly of animal protein such as fish meal and powdered blood, the coarse protein content being thereby increased to more than 15 percent. Third has been a mobilization of the masses to improve their feeding methods, reversing the customary method of feeding hogs poorly during the early stage of growth to build up their framework and feeding them well in the late stage of growth to build up their framework and feeding them well in the late stage to fatten them. Feedings of hogs until they reach a weight of 100 to 120 jin should be good, but hogs should not be allowed to eat better and better. All that is necessary is to assure that their nutritional requirements are met, while controlling growth at the proportion of 1 jin of flesh for each 3 jin or so of feed given each day, and a gradual cutback in feeding during the middle and late stages, nutritional levels being gradually reduced from the 70 percent level of the early period to 15 or 13 percent. Fourth is a change in butchering weight. After feeding for about 150 days, when the hogs have reached a weight of between 160 and 180 jin, they should be slaughtered.

Earliest Change Into the Work Promotion Stage

Zhang Zhao [1728 3564], Provincial Animal Husbandry Veterinary Medicine Society deputy director and professor at the Jiangsu Academy of Agricultural Sciences, gave lectures and showed slides in a combination of theory and practice to report on the history and present state of breeding and feeding lean pork hog species in the United States, Denmark, Canada, and Japan, and to report on successful experiments in the breeding of lean pork hog species done in Heilongjiang and Zhejiang provinces. Professor Zhang is 70 years old this year. In 1934 he raised and studied American Curoc hogs. At that time, this type hog was also a fatty one in the United States, but after 45 years the United States bred it into a lean pork type hog with a very high lean pork rate. So experiences exist abroad that can be borrowed, and inside China and within the province too there have been experiments. We can speed up our efforts a little, and now we should rapidly transfer to the promotion stage. The four techniques reported above for the breeding of lean pork hog species may not be gradually spread through the adaptation of general methods to specific local situations. The running of superior variety hog farms, the promotion of binary and ternery hybridization, the artificial insemmination, the raising of pigs from the south in the north, and the supplying of different cuts of pork with increased differences in price for the fat and the lean, etc are real steaps that have already been taken along this path.

Seriour attention on the part of leaders to change the policies that encourage the raising of overly fat hogs and to encourage the raising of hogs with a high lean pork rate will be a useful measure. Jiangsu Province annually uses between 6 and 7 billion jin of grain to raise hogs, but the pork it gets in return is largely fat that the society does not welcome. Should not promotion of the raising of lean prok hog species be placed on daily agendas with all possible speed?

JILIN

TWO PREFECTURES BECOME MAJOR COMMODITY GRAIN BASES

Beijing RENMIN RIBAO in Chinese 3 Aug 82 p 1

[Article: "Large Consecutive Year Grain Increases in Siping and Tieling Prefectures. Learning From One Another to Make Up Each Other's Deficiencies and Hasten the Building of Commodity Grain Bases; All-around Development of Forestry, Animal Husbandry, Sideline Occupations, Fisheries, and Industry, Collectives and Commune Members Gradually Becoming Prosperous"]

[Text] Siping Prefecture in Jilin Province and Tieling Prefecture in Liaoning Prefecture, located in the middle and upper reaches of the Liao He, have learned from each other, helped each other, and made up each other's deficiencies for tremendous increases in grain production year after year and the all-around development of forestry, animal husbandry, sideline occupations, fisheries, and industry, making an increasingly great contribution to the country. These two prefectures have become major commodity grain bases in the two provinces.

The story of how Siping and Tieling prefectures learned from each other to increase production and earnings has been told far and wide on both banks of the Liao He. It has been learned from authorities in both prefectures that last year Siping Prefecture's grain output totaled 5.38 billion jin, up 20 percent from the year before, and commodity grain turned over to the state totaled 2.66 billion jin, up 40 percent from 1980. Last year Tieling Prefecture's grain output totaled 4.82 billion jin, up 9 percent from 1980, and commodity grain turned over to the state amounted to 2.31 billion jin, up 20 percent from 1980. Development of production has occasioned a flourishing of the economy, and both the collective and commune members have gradually become prosperous.

Siping and Tieling are neighboring prefectures. Following the Third Plenary Session of the 11th Party Central Committee, both Siping and Tieling prefectures were designated commodity grain bases. They very rapidly increased grain production while at the same time actively developing economic diversification, realizing the common hopes of cadres and masses in both prefectures. At that time Tieling Prefecutre's agricultural production was more highly developed than Siping's. Siping Prefecture CCP Committee First Secretary Huo Mingguang [7202 2494 0342] went down into communes and brigades to investigate and study, and the production experience of labor model Chen

Dianshuang [7115 3013 7175] of Shahe Second Brigade in Zhenxing Commune in Tieling Prefecture aroused his very great interest. He invited Chen Dianshuang to Siping to give lectures and teach his experiences. Chen Dianshuang's experiences in the use of phosphate fertilizer blossomed in Siping.

The attitude in Tieling Prefecture used to be: Agricultural production is intensive in the south and extensive in the north, and grain yields are high in the south and low in the north; one should learn from the south and not from the north. Last year Siping Prefecture promoted the production experiences of Chen Dianshuang and of Changtu County in Tieling Prefecture and, with the aid of the weather, total grain output climbed to 5.38 billion jin, 500 million jin higher than for Tieling Prefecture.

PROVINCIAL CONFERENCE HELD ON ECONOMIC DEVELOPMENT OF MOUNTAIN REGIONS

Jinan DAZHONG RIBAO in Chinese 10 Jul 82 p 1

[Article: "All-around Launching of the Building of Mountain Regions to Hasten Development of the Rural Economy. Provincewide Mountain Region Work Conference Calls Upon All the Party and All the People to Mobilize. Conference Discussed Programs, Policies, Plans, Measures, and Leadership Problems in Mountain Region Constuction. Comrades in Charge from Provincial CCP Committee, Provincial Government and From all Prefectures, Municipalities, and Counties Join in Tree Planting Activities in Wulian County"]

[Text] A provincewide mountain region work conference lasting for 6 days concluded on 8 July in Wulian County. The conference called upon CCP Committees and governments at all levels in mountain regions to take in hand as an urgent strategic task the rapid construction of mountain regions, to go into action, to adapt general methods to local situations to do good planning, and to lead the broad masses of cadres and people to do a good job of mountain region construction in order to change the face of mountain regions with all possible speed, and make a new contribution in the all-around balanced development of the province's agricultural economy. Before the conference began, comrades in charge from the Provincial CCP Committee and provincial government went to more than 10 mountain counties including Wulian, Yingxian, and Liwu to investigate and study. Comrades in charge from municipalities and counties everywhere went to Wulian and Yingxian counties to inspect and study, and they made rather well thought out preparations. During the conference, the Wulian County CCP Committee, the Yingxian County CCP Committee, and the Jietou Commune CCP Committee from Wulian County gave briefings on experiences. The CCP committees from Laiwu, Rizhao, Xixiz, Zhucheng, Kuanxian, and Mengyin counties, the CCP committees from Haiqing Commune in Jiaonan, from Mada Commune in Taian City, the Beizhuang Commune in Zaozhuang City, the Ezhuang Commune from Zibo City, and Sizhang Commune from Sishui, and the General Party Branch and Party branches of the Xiadingjia Production Brigade in Huangxian, from Nan yan Production Brigade in Yidu, and from Liujia Production Brigade in Licheng made illustrative remarks.

Comrade Bai Rubing [4101 1172 3056], Provincial CCP Committee first secretary, made a major speech at the conference on the subject of "Mobilization of All the Party and All the People to Hasten the Pace of Mountain Region Construction."

The conference acknowledged that in order to hasten the building of mountain regions, the entire province from top to bottom will have to have a renewed understanding of the mountain region. For a long time many comrades have lived in the mountains without understanding the mountains. They have linked "mountains" and "poverty" together, and have carried around a notion of "barren mountains and unruly rivers." Very clearly such ideas are wrong. Granted that in mountain areas slopes are steep and ravines numerous, the soil infertile and water lacking, and communications difficult, these are their weaknesses. But in mountain regions the land area is vast, resources are abundant, the production potential is great, and ways to earn income are numerous. These are their tremendous strengths. These are strengths that plains areas cannot match. In the province's mountain and hilly regions, average amounts of cultivated land per capita is 1.4 mu and the average amount of mountain land along streams is 2.3 mu. Were these mountain areas along streams to be planted to grain, the yields from 3 mu would be equal the yields from 1 mu on the plains. Were fruit trees planted on them or were they used for timber forests, earnings from a single mu would equal those from several mu of grain. It should also be realized that if farming, livestock raising, mining, and processing industries were carried out in the mountain regions, economic effectiveness would be even greater. In some mountain regions production has not been well handled and the standard of living of the masses of people is fairly low. This is not the result of resources not being abundant there but rather because leaders do not have a correct appreciation of mountain regions. In beginning construction of mountain regions, their understanding has come late and their actions are slow. "If there is a mountain, it holds a treasure, but it is not easy to find." Only if one genuinely realizes the wealth that the mountain regions contain and is adept at adapting general methods to local situations to fight his own battle from a position of dominance, the mountainlands along streams will then become "money trees" and "cornucopias."

As to what construction program to pursue in mountain regions that would be of crucial importance to mountain region economic development, the conference summarized the lessons of historical experience and recognized the need to take a firm grip on the major mountain region contradictions, to define the main direction of attack, and to persevere overall in carrying out the Central Committee's program for "positively no relaxation in grain production while actively developing economic diversification," persevering in taking forestry as the key link in a combination of farming, forestry, and animal husbandry for economic diversification and all around development to take the path of "relying on the mountain for food to eat and nurturing the mountain that feeds one." Facts have shown that in development of mountain region agriculture and the entire mountain region economy, the decisive element is forests. Forest trees are the main switch and the hub of the natural world. They not only provide lumber, firewood, fruits, and such direct economic benefits, but they hold water resources, preserve water and soil, break the winds and stabilize sands, regulate climate, purify the air and provide such indirect benefits. As the masses say, "To grow many trees in the mountains is the equal of building a reservoir. When it rains, they can swallow it; when it does not rain, they can spit it up." "A few trees with a little water and much ground becomes wet;

with trees and grass, there is water." Of course, to maintain that forests are the key link in mountain regions is positively not the same thing as "concentrating only on one thing." Fundamentally speaking, forestry and farming, the livestock raising industry, processing industries, and other industries are mutually interdependent and mutually promoting. No one of them can be dispensed with. Simultaneous with development of forestry production must come rational arrangements for diligent attention to grain production, the adaptation of general methods to local situations for development of the livestock industry, industrial sideline occupations, processing industries and mining industries for active development of economic diversification, so that forests will advance grain and grain will advance forests for the all around development of farming, forestry, livestock raising, sideline occupations, and fisheries.

In view of the almost infinite variety of natural conditions in the geology, topography and climate of mountain regions, the complexities of situations, and the fairly numerous avenues for production, the conference expressed the view that mountain region construction must have a battle plan consistent with objective realities, i.e. an overall plan. Only by having a good plan can it be possible to set combat objectives and the main direction of attack and only then will it be possible to do overall planning taking all factors into account and make comprehensive arrangements, and only then will it be possible to avoid blindness, to increase scientificness, and to garner maximum economic benefits. In summarizing the experiences of various jurisdictions and formulating mountain region construction plans, problems to which emphasis should be given are the following: Centralized planning must be done for mountain waters, fields, forests, and roads, tackling them in a comprehensive way, both giving attention to current production and placing emphasis on long range construction. In the building of production and the development of science, culture, education, and health endeavors, overall considerations must be given. Full use must be made of the role of science and technology in the building of mountain regions, and all trades and industries must be organized for vigorous support of mountain region construction. Each jurisdiction must be permitted to adopt different methods of tackling problems and to carry out various different kinds of production responsibility systems, to establish different kinds of operations so as to fully arouse the enthusiasm of state-owned farms, people's communes, production brigades, production teams, vocational teams, and commune member households. Only in this way can concerted efforts be made and everybody keep in step in advancing into the mountains, each fighting his own war from a dominant position to hasten the pace of mountain region development.

The conference emphasized that development of the mountain regions is a long term and extraordinarily arduous task, the crux of which lies in the strengthening of leadership so that there will be leadership teams capable of conscientiously and thoroughly carrying out the party's line, programs and policies, that that will be imbued with an ardent sense of revolutionary missior and a spirit of creativity that is able to take the lead in action to open a new situation. The advanced units that spoke at this conference all possessed these characteristics. However, today some leadership teams in mountain regions lack great zeal. They attempt nothing and accomplish nothing.

All they do is keep doing the same old things, never starting anything new, and the natural situation in mountain regions remains the same old way year after year. In the case of such units, firm attention has to be given to ideological rectification and reorganization to help them establish strong leadership nuclei, to rouse their revoutionary spirit, and to increase their fighting capacity. In mountain regions every leadership team and every member of the Communist Party should be like the comrades from Wulian in their resolve to create wealth for the people and to leave behind green mountains and clear waters for posterity and positively not bequeath to them barren mountains and bald ranges. It is necessary to have lofty ideals and great ideals, to carry forward the spirit of the foolish old man who "would not stop digging the mountain," to struggle arduously, to charge forward at the head of one's men, to set a personal example, and to be a leader in the building of mountain regions.

Comrades who attended the conference studied pertinent instructions from the Central Committee and discussed Provincial CCP Committee and provincial government decisions (revised draft) on hastening the building of construction in mountain regions, as well as Comrade Bai Rubing's report. They compared the experiences of advanced units and summarized the lessons of their own experiences, expanded their horizons, increased their undertsanding, strengthened their sense of urgency and sense of responsibility for development of mountain regions. Everyone expressed themselves as determined to act in accordance with the call of the Provincial CCP Committee and provincial government, to fit actions to words, to bring about a change in the appearance of mountain regions within 3 years, to see results in 5 years, and to bring about great changes within 10 years, entirely afforesting the Yilin mountain lowland areas along streams by 1985 and substantially completing afforestation by 1990, so that all of Shandong will be greener and more luxuriant.

In order to give expression to the resolve to build up the mountain regions and to give impetus to a mass movement for taming the mountains and creating forests, comrades in charge at the Provincial CCP Committee and provincial government such as Bai Rubing, Li Zhen [2621 2182] and Zhou Zhen [0719 2182], and comrades in charge attending the conference from departments directly under the jurisdiction of prefectures, municipalities, counties, and the province planted gingko trees and pine trees at Wulian County.

SCIENTIFIC TECHNIQUES FOR RAISING YIELDS CONVEYED TO PEASANTS

Jinan DAZHONG RIBAO in Chinese 4 Aug 82 p 3

[Article: "Reliance on Scientific Techniques to Improve Low Yield Fields. Experiments Increase Yields By 80 Percent on 100 Mu of Low Yield Wheat Fields in Huimin Prefecture"]

[Text] In a year of great drought, the Huimin Prefecture Science Commission has won remarkable results, increasing yields by 80 percent in experiments with techniques to increase yields from low yield wheat fields on a 100,000 mu experimental area. Yields have averaged 379 jin per mu, a 170 jin increase over the average yields for the previous 3 years. This action has been praised by the peasants as "the way for low yield fields to make a new start."

Low yield fields are the "old big difficulty" in that prefecture's development of agricultural production. The low yield field area for crops such as wheat, corn, soybeans, and cotton amount to a general 70 percent of the total area sown. Low yield fields with wheat yields of less than 150 jin per mu have occurred every year for the past 5 years over an area of more than 3 million mu. In order to improve these low yield fields through the use of scientific techniques, the Huimin Prefecture Science Commission launched experiments on the foundation of average 65 percent yield increases effected through the use of yield increase techniques last year on low yield corn, soybean, and cotton fields. Last year they again set up experiments with techniques for increasing yields on 100,000 mu of low yield wheat fields. During the entire growing season for wheat, they used 17 technical measures including replacement with superior varieties, increased fertilization with phosphate fertilizer, earliest possible sowing, and reasonably close planting. In order to verify each technique scientifically, at 23 sites they set up phosphate fertilizer experiments, comparisons of varieties, and watering season experiments as part of 13 different experiments. They planted 62.6 mu of experimental fields, and intensified qualitative and quantitative analysis of all techniques used in experiments.

In order to assure smooth conduct of experiments, within eight experimental areas they set up individual leadership teams composed of 55 persons in charge in counties, communes, and departments concerned, technical advisory groups composed of 73 specialized scientific and technical personnel, and eight experimental area technical teams. Throughout the period of the experiments, all experimental areas jointly conducted 39 technical training classes to train 5,846 attendees. They ran 26 technical boradcast lecture courses to a listnership of more than 22,000. They printed 21 pieces of technical data, which they issued in more than 50,000 copies. They also used night schools, country market publicity, performances in fields, and such methods to get techniques into the hands of the broad masses of peasants. In addition, they also instituted responsibility systems linking techniques to output, production responsibility systems, and cadre personal responsibility systems within the experimental areas, and they used contract agreements, economic methods, and systems of responsibility to fully arouse the enthusiasm of cadres, peasants, and scientific and technical personnel to do a good job of experimental work.

SUCCESS OF ECONOMIC DIVERSIFICATION IN ONE PREFECTURE HAILED

Jinan DAZHONG RIBAO in Chinese 15 Jul 82 p 2

[Article: "Value of Good Plans Lies In Their Implementation; Remarkable Increase in Earnings from Economic Diversification in Taian Prefecture"]

[Text] The Taian Prefecture CCP Committee and government administrative offices have gained excellent results by emphasizing attention to the implementation of economic diversification production plans. As of the end of April, total earnings from economic diversification for the prefecture as a whole had increased by 34.2 percent over the same period last year. Three counties of the prefecture's eight counties and municipalities had earnings that were more than 50 percent greater than last year.

Formerly some counties and communes in this prefecture were frequently content with simply formulating plans for economically diversified production, but they did not devote much attention to the implementation of plans. As a result plans were not fulfilled, and some of them came to nothing. In order to change this state of affairs, this year the Prefecture CCP Committee and government administrative offices changed its method of leadership. It first achieved shortrange implementation of longrange plans, carrying out regular inspections in farming seasons on production links. The main thing they tackled during the first half of the year was the farming industry and the breeding industry. They supervised, urged on, and inspected, used every available means to combat drought to grow economically diversified crops, gave strict attention to the raising of newborn livestock, assuring increased output and increased earnings for the last half of the year. Second, they used contract agreements to put production plans into effect with teams, households, and individuals. In this regard, all counties sent out work teams to emphasize help to communes and brigades in further perfecting and stabilizing economic diversification contracting systems of responsibility, and in summarizing experiences at key points to guide work over wide areas. In addition they used loans or funds provided by collectives to assist hardship units and individuals in the implementation of production programs and the development of economic diversification, helping them do a good job of existing industrial sideline production projects, in closing economic gaps, in lowering production costs, and improving economic effectiveness. As a result of adoption of these measures, this year the prefecture has expanded its "economic fields," and plans for 244,500 mu have been entirely implemented. This measure alone can increase earnings by 48.1 million yuan. In the task of spring season tree planting and forestry management, in addition to large scale efforts to transform mountains through afforestation and making the four besides [besides roads, streams, villages, and houses] green, they intercropped tung trees and grain over a 366,300 mu area and newly planted 1.89 million fruit and nut trees, and 9,500 mu of mulberry groves. The prefecture's collective and individual raising of livestock and poultry of all kinds also increased remarkably. Fairly great increase occurred in the numbers of cattle, sheep and goats, rabbits, and geese raised, and the number of live hogs rose again. The number of long haired rabbits increased by 1.5 million. Industrial sideline production also saw new development in the prefecture's production brigades and production teams, and more than 10,000 new jobs in crushing stone, building, and food and beverage service have come into being.

BRIEFS

GRAIN DRYER BUILT--The 5HY-2 grain dryer designed by the Provincial Farm Machinery Institute and the Weifang Prefecture Farm Machinery Institute and manufactured by the Linqu County Tractor Plant is of advanced design, is well-made, is sensibly engineered, is easy to set up, use, and move, and operates reliably. Recently technically approved, this machine operated in 25°C temperature at a relative humidity of 80 percent to dry grain with a 25 percent water content. At a water removal rate of 10 percent, it dried 2 tons of grain an hour for storage after a single drying. After drying, grain quality did not deteriorate, and it met nationally formulated standards. This is the first medium size grain drying machine to be designed and manufactured in China, and it is suitable for use on medium and small size farms and granaries. YUNCHENG PREFECTURE'S MEASURES FOR FIGHTING DROUGHT EXPLAINED

Beijing NONGGUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, Aug 82 p 27

[Article by Yuncheng Prefecture CCP Committee Secretary Tong Yun [0104 7189]: "Persevere in Protracted Combat Against Drought to Win A Bumper Harvest for the Year as a Whole"]

[Text] Yuncheng Prefecture is the main grain producing area of Shanxi Province, yet it is an area where 9 out of 10 years are drought years. Total rainfall for the 1950's was 700 millimeters; during the 1960's, it was 600 millimeters; and total rainfall during the 1970's declined to from 400 to 500 millimeters. Since Liberation, 27 of 34 years have had protracted drought with little rain. Spring drought followed by summer drought occasions very great hardships for the development of agriculture.

Faced with such a grim problem, in its guidance of agricultural production the Prefecture CCP Committee has gradually established a mentality of protracted combat against drought making perseverance in protracted combat against drought a strategic matter of major importance that must be given attention in agricultural production. Since the Third Plenary Session of the 11th Party Central Committee, in particular, it has proceeded from realities both building water conservancy to improve upon nature and to summarize and promote traditional mass experiences in combat against drought to meet nature. It has repaired its house before it rains, guarded against drought when there was no drought, combatted drought when there was drought, and persevered in combat against drought to win bumper harvests.

First of all we have assiduously summarized and promoted the traditional farming methods of drought stricken Wanrong and Linyi prefectures of "harrowing whenever it rains," and the method for combatting drought and conserving soil moisture used by Dongguanzhung in Wenxi County of raking after plowing on hot summer days to "put summer rains to use in spring," and leveling fields to make the surface crumbly and the bottom solid to reduce moisture evaporation. The masses refer to this method as "being busy for three days after a rain, busy at conserving soil moisture." At the same time every available means is used to store water that falls from the sky. Most of the prefectures 132 reservoirs store water during spring to make ready the water needed during the three 10 day periods of the hot season.

Last August the summer drought was severe. I went to Sanquan Commune in Xinjiang County where together with comrades in charge from the County CCP Committee we watched them use the grape reservoirs built of small amounts of water from small springs. This invention of the masses is handy and easy to use, requires little expenditure of money, and shows quick results. Following discussions with the local masses, full use was made of small spring water resources to enlarge the irrigated area by more than 20,000 mu. Next we spread this experience throughout the prefecture, Ruicheng and other counties made full use of small amounts of water from small springs to build grape reservoirs with very good effectiveness. More than 2,500 small water conservancy construction projects have now been built throughout the prefecture with wells taking the place of ponds, and stations taking the place of ponds for storage when it rains and use when it is dry to expand the well-irrigated area and increase ability to combat summer drought.

Second, while summarizing and perfecting agricultural production responsibility systems, we conscientiously established and perfected water conservancy responsibility systems using every available means to increase the water utilization rate for water conservancy facilities. Many years practice has shown that eating out of a large common pot does not work, and that "drinking out of a large pot" sows endless seeds of disaster. First, we summarized and promoted the experiences of Qiaoxue Production Brigade in Wanrong in centralized management and centralized maintenance of wells, and centralized provisions for persons to look after the wells within the institution of commune member ticket purchases for irrigation. The advantages of this responsibility system were both maintenance of water conservancy facilities to make the most of the role of water conservancy facilities, and arousal of the enthusiasm of commune members for irrigating their fields while closing loopholes in payment for water and electric power. Now, more than 85 percent of water conservancy facilities and deep wells have set up different forms of responsibility systems, which not only save water and electric power, but also make for faster and better watering of the fields. Benefits from irrigation have increased remarkably, and the in-service rate and the utilization rate for equipment has increased from the former 55 percent to better than 80 percent. Since last year the irrigated area throughout the province has expanded by 212,000 mu. Water management units have also engaged in economic diversification for earnings totaling 2,050,000 yuan to create an all time high.

Third, in light of the drought that characterizes Yuncheng Prefecture, we have bred and introduced more than 10 drought resistant varieties of wheat and cotton and have increased fertilization with organic fertilizer, rather effectively withstanding drought disaster onslaughts. Formerly, as soon as drought stricken areas encountered the summer drought, between 400,000 and 500,000 mu of autumn crops would be damaged. Now, the drought resistant crop varieties that have been bred and introduced ripen relatively early, some of them avoiding the summer drought. For example when corn was planted where wheat was growing, for the 500,000 mu of intercropped corn, flowering and booting stages avoided the choking drought. In addition, we also gave serious attention to increase in organic fertilizer to improve the soil's ability to withstand drought. It has been found that between May and October fertile soil with an organic content of 1.11 percent evaporates between 14 and 19 percent less moisture than infertile soil with an organic content of 0.6 percent. Were the infertile soil to be transformed into fertile soil, that would be the same as 520 millimeters of rainfall a year being increased to 750 millimeters. Consequently, in our crop patterns, we must arrange for the green manuring and return to the fields of stalks and stems on more than 100,000 mu to increase soil fertility and ability to preserve moisture.

Since last winter Yuncheng Prefecture has not had a soaking rain, and the drought continues. The masses continue to fight drought, striving to win a bumper harvest for the year as a whole.

RAINY SEASON AFFORESTATION STATISTICS GIVEN

Beijing RENMIN RIBAO in Chinese 26 Jul 82 p 1

[Article: "More Than 240,000 Mu Afforested in Shanxi During Rainy Season; Firm Grip Taken on Advantageous Opportunity to Rush Plant"]

[Text] As the year rolled into July, the Shanxi rainy season tree planting and afforestation campaign steadily unfolded from north to south. As of 22 July more than 240,000 mu had been afforested throughout the province though afforestation of 226,000 mu had been anticipated. In former years the onset of July brought continuous overcast and rainy weather in most parts of the province. This year, once the rainy season began, rainfall in many places tended to be light. Faced with such unfavorable weather, all locales bided their time, getting ready to plant trees and do afforestation before the arrival of the rains, and once a soaking rain fell, they immediately rush transplanted and rush planted. The 21 counties in the western mountain region of Shanxi Province, which are part of the three norths shelter forest system, have afforested more than 172,000 mu as of now. Within less than 20 days Huguan County afforested more than 35,000 mu.

While all jurisdictions in Shanxi were using people to afforest, they also began active airplane sowing for afforestation. Statistics from the four counties of Bianguan, Kefeng, Wuzhai, and Lishi alone show that during this year's rainy season aircraft sowed seeds for the afforestation of more than 85,000 mu.

FIFTH CONSECUTIVE BUMPER RAPESEED HARVEST REPORTED

Chengdu SICHUAN RIBAO in Chinese 10 Jul 82 p 1

[Article: "Province Overfulfills Rapeseed Procurement Plans; Bumper Rapeseed Crops Harvested For 5 Consecutive Years"]

[Text] This year Sichuan harvested a bumper rapeseed crop for the fifth year in a row. Output totaled more than 2.16 billion jin, a more than 30 percent increase over last year and exceeding the level of any other period in history. As of 5 July, more than 1.99 billion jin of rapeseed had been purchased in the province, 489 million jin more than the amount called for in procurement plans handed down by the province for 32.3 percent overfulfillment of plan.

In order to do a good job in this year's rapeseed procurement work, before the rapeseed was harvested grain departments conducted training of personnel, increased the number of network outlets, built and repaired a group of granaries and oil storage facilities, and used various methods to give wide publicity to the peasants about no changes in this year's rapeseed procurement policies, no changes in procurement prices, no time limit on procurement, and no limit on quantities that would be purchased, fully satisfying peasant requirements and demands in selling rapeseed. During procurement all jurisdictions strictly carried out a system of classification and grade inspection, overcoming any attempts to deprecate quality in order to drive down price or inflating quality in order to raise price, and assuring quality of rapeseeds put into storage so that both the country and the peasants would stand to gain. Now, peasants everywhere are continuing to sell the state their sun-dried rapeseeds.

LARGE INCREASE IN CONSUMER GOODS PURCHASES REPORTED

Chengdu SICHUAN RIBAO in Chinese 13 Jul 82 p 1

[Article by Finance and Trade Department, Sichuan Provincial Statistical Bureau: "Province's Rural Markets Unprecedentedly Active; Great Bumper Harvests From Crops Sown in Late Autumn; Tremendously Increased Purchases of Agriculture and Sideline Products"]

[Text] This year the province's rural villages have instituted production responsibility systems everywhere; a bumper crop of crops sown late last autumn has been joyously harvested; and quantities of agricultural and sideline products purchased by the state have increased tremendously. As of the end of June, 64.7 percent more rapeseeds had been purchased than last year, 14.4 percent more grain, 4.3 percent more spring cocoons, 62.6 percent more spring vegetables, and 57.8 percent more jute. Purchases of agricultural and sideline products during the first half of the year totaled 2.865 billion yuan in value, a 22.6 percent increase over the same period last year. Cash disbursements by banks and credit cooperatives to rural villages this year for the purchase of agricultural and sideline products were more than 400 million yuan greater than for the same period last year, an increase of 48.5 percent. As a result, rural markets were unprecedentedly active during June of this year. Social commodity sales figures for the province during June stood at 1.495 billion yuan, 16.6 percent greater than during the previous month and 16.6 percent greater than during the same period last year, for a new all time high for social commodity retail sales figures for June. Rural retail sales of consumption goods amounted to 604 million yuan, 26.4 percent and 17.9 percent greater than for the previous month and the same month last year respectively. Prefecture by prefecture breakdown shows greatest increase in retail sales figures for grain and edible oils. A breakdown by varieties shows greatest increase was in agricultural means of production. June retail sales figures were 33.2 percent and 28.0 greater respectively than for the previous month and for the same month last year. Chemical fertilizer sales to rural villages increased by 44.4 percent over the same month last year. Pesticide sales increased by 53.9 percent over the same month last year. Sales were very brisk for all major industrial goods such as cotton-polyester cloth, chemical fiber cloth, cotton cloth, watches, transistor radios, sewing machines, bicycles, soap, and laundry powder.

Problems in markets deserving of attention just now are as follows: Stocks of goods in storage in commercial departments have increased very greatly requiring active assembly of industrial goods to be sent to the countryside. As of the end of June, commodities stored in large and medium size cities and in county seats accounted for 76.3 percent of the total value of stored goods; commodities sent to the countryside amounted to only 23.6 percent of value. Market situation estimates by some grassroots level commercial departments following the bumper harvest of autumn planted crops were inadequate. They did not dare bring in goods courageously, with the result that in some places Chongqing and Shanghai wristwatches, transistor radios, cool foam shoes and chemical fertilizer ran out of stock.

SUMMER GRAIN PROCUREMENT QUOTAS OVERFULFILLED

Chengdu SICHUAN RIBAO in Chinese 14 Jul 82 p 1

[Article: "Province's Summer Grain State Procurement Quotas Overfulfilled"]

[Text] This year Sichuan Province has once again harvested a bumper summer grain crop, output rising by more than 10 percent over last year. As of 5 July the province had already exceeded state summer grain procurement quotas by 8.8 percent, the amount in storage being 550 million jin more than for the same period last year. Quality of grain in storage was also better than last year, and the wheat flour milling rate was higher than last year.

Under the leadership of local party and government, grain departments at all levels this year assiduously carried into effect the principle of concurrent concern for the welfare of the country, the collective and commune members as well as price policies, and actively helped production teams implement household by household sales quotas, institute the setting up of outlets in designated stretches, arrange appointments to turn over grain, and improve service attitudes as a convenience for commune member grain sales to the state.

While actively purchasing, grain departments everywhere also gave attention to provisions for mass welfare, promptly making arrangements for the small number of people whose grain rations did not last until the fall crop could be harvested.

POLICY REGULATIONS ISSUED ON RURAL ECONOMIC DEVELOPMENT

Chengdu SICHUAN RIBAO in Chinese 14 Jul 82 pp 1,2

[Article: "Provincial CCP Committee and Provincial Government Enact 10 Policy Regulations to Meet New Circumstances and To Hasten Rural Economic Development"]

[Text] On 29 June, the Sichuan Provincial CCP Committee and Sichuan Provincial People's Government issued "Policy Regulations on Various Problems in the Hastening of Sichuan Province's Rural Economic Development, the text of which said as follows:

In order to hasten Sichuan Province's rural economic development, while continuing to carry out a series of effective programs and policies from the Central Committee and the Provincial CCP Committee, in order to meet new circumstances it is necessary to adopt some policy measures. Following full discussion by the Provincial CCP Committee work conference, the Provincial CCP Committee and provincial government enacted the following policy regulations.

1. In the work of instituting the "two systems" in forestry, all places where conditions permit may suitably allocate more privately retained mountains for commune members, and designate barren mountains, wasteland slopes, and unused land that the collective cannot readily use for the planting of trees and afforestation by commune member households. Ownership of the land will still belong to the collective, but ownership of the forest trees will belong to commune members with the right of inheritance. Commune members should be energetically encouraged to plant small orchards, small mulberry groves, and small tea gardens as well as to grow other economic woodlands in front of and behind their houses, on private plots, on privately retained mountains, and in places designated by production teams, all income reverting to themselves, with no changes to be made for a long period of time. The state and collectives are to lend active support in the supply of seedlings and technical guidance.

Collectively owned continuous tract woodlands are to institute "four specializations and one contracting." Economic woodlands in cultivated lands and along fields should be contracted out together with the fields as part of a unified whole, earnings or benefits to be paid to hire authority from the assumption of sole responsibility for task completion being proportionally divided so the directly involved enterprises gains more the more he works. Bald mountain and barren slope tracts that lend themselves to collective endeavors should be run by specialized units and specialized teams organized by production teams. Alternatively, they may be handled as responsibility mountains and contracted out to commune member households for the planting of trees, no changes being made for a long period following contracting, benefits being divided between the collective and the commune members, the commune members getting the greater share.

2. State owned forests that the state is unable to take care of should be contracted to the care of on-site communes and brigades with proper remuneration being given them. Railway and highway right of ways, the banks of streams and trunk irrigation canals, and the areas around reservoirs that have already been afforested are to be strictly protected. Where trees have not yet been planted, units in charge may do the afforestation and retain ownership of them, or they may afforest jointly with communes and brigades, proceeds being proportionally divided. Alternatively, following agreement from units in charge, nearby communes and brigades may do the afforestation, the trees reverting to the ownership of the commune or brigade or to the commune members, However, felling of trees may be done only on the authority of units in charge.

3. In high mountains or places way back in the hills, attention should be devoted to the building of basic farmlands and to increasing yields per unit of area. While assuring steady increases in total grain output, steep slopes that should gradually be withdrawn from cultivation and revert to forests or pasturelands may become reserve lands for production teams and contracted to specialized teams or specialized households for the planting of trees and the growing of grass. Responsibility lands that have been contracted to commune member households may, so long as fulfillment of payments to higher authority are assured and with no changes for a long period of time on contracted lands, be afforested by contracting households, earnings being retained by them. The foregoing methods may also be used by collectives to provide contracting households with seedlings for planting with payment of stipulated remuneration, a certain amount of earnings being paid to higher authority, or earnings being proportionally divided, the commune members receiving the greater portion.

4. In 1980 the Provincial CCP Committee decided that beginning in 1981, "the provincial treasury would annually allocate about 15 million yuan for use within the province (including mountain areas of the province) to subsidize communes and brigades to afforest 1 million mu with quick growing high output timber." In the same year, a provincial government document made specific arrangements in this regard. This is a major policy for hastening the building of forestry

within the province, which has gained the deep support of the masses. Departments concerned should conduct an inspection of the implementation of last year's decisions and of arrangements for this year's plans, solve existing problems, and assure that policies continue to be honored. Funds for the growing of forests and development funds may be used only for the planting of trees in afforestation; they may not be diverted to other uses.

5. In 1980 the Provincial CCP Committee decided to allocate 395 million jin of grain as assistance for use in helping mountain regions and poor brigade and minority nationality area communes and brigades to rest and recuperate, to readjust the structure of their agriculture, and to develop production. Practice has shown results to have been very good. The ordinally prescribed time was 3 years, and it has now been decided that this policy is to continue in force until 1990. Norms given by the province to prefectures, municipalities, and zhous remain unchanged; norms from prefectures, municipalities and zhous to counties, and norms from counties to communes and brigades may be suitably readjusted on the basis of changed circumstances in the development of production, and in accordance with the principle of rational utilization. These grain norms should be used by counties in centralized planning, mostly in the withdrawal of land from cultivation for reversion to forests or pasturelands and for reducing procurement or setting sales in production teams that have low yields and are short of grain, as well as for assistance in the building of forestry, livestock industry or economic diversification bases. Generally there is to be no linking of state procurement of agricultural and native sideline products to grain.

6. In order to give mountain region counties a little more initiative on the grain issue in order to carry out readjustment of their agricultural structure, it was decided to institute assumption of full responsibility for grain in high mountain areas (not including the three zhous). In the assumption of full responsibility method, because of the prevailing margin between procurement and sales in areas concerned with some fixing amounts of assistance, some fixing amounts to be paid to higher authority, some seeking balance, a corresponding system of sole fiscal responsibility has been instituted and guaranteed without change for 5 years.

In mountain counties where financial outlays are greater than financial income year after year, sole responsibility for fiscal subsidies is to be tried out. This entails taking the 1982 budget as the base figures, instituting fixed amount subsidies for the difference between expenditures and revenues, with no change guaranteed for 3 years. Increased revenues and savings on expenditures are controlled by counties and used principally for development of the economy of the mountain area, for the building of highways, for cultural and educational endeavors, and for the popularization of science and technology. Following assumption of sole responsibility, except for the readjustment wages of administrative enterprenural units, which will be borne by the province, all other reduced revenue and increased expenditure matters newly approved by higher authority will be borne by the county assuming sole responsibility.

In the matter of specific methods for the three prefectures of Fuling, Wanxian, and Yaan in which public funds expenditures are greater than revenues the province will institute a system of sole responsibility for fixed sum support on the basis of the foregoing principle for the prefectures. Sole responsibility methods for counties are to be decided by prefectures. For remaining mountain region counties in which public funds expenditures are greater than revenues, prefectures will institute sole responsibility for counties, and the province will continue to maintain without change the prevailing financial system in these prefectures; however, in figuring the financial quotas for these prefectures, the increased fiscal revenues of counties assuming sole responsibility are to be eliminated.

7. In instituting base figure procurement and proportional procurement of agricultural and sideline products, basic stability is to be maintained. A conscientious job is to be done with the contracts system. State centralized procurement, assigned procurement and allocation quotas are to be assured fulfillment. For products designated by policies as being left to collectives and commune members for their own disposition, the right of self-determination is also to be assured. Specific regulations handed down by all trades and industries in this regard must be in total agreement with the regulations of the Provincial CCP Committee and provincial government.

8. Institution of various forms of joint operations and integrated operations is a path that has to be taken to hasten development of the rural economy. While adhering to the principles of voluntary participation, mutual benefit, equality, and discussion, encouragement should be given the breaking of regional, trade and ownership lines for development of various forms of joint enterprises. Units participating in jointly run enterprises are to maintain their original ownership, their command relationships, their basic accounting units, and their tax and earnings calculation and payment relationships without change, basic accounting units figuring output value and figuring tax levies to be collected. All levels of CCP committees, government, and departments concerned are to enhance guidance to the various kinds of joint enterprises, avoid duplication in the construction of plants, and help in the distribution of economic benefits to harmonize relationships of all parties. Design commissions, economic commissions, and state enterprises concerned at all levels are to adopt various forms of joint operations and economic and technical cooperation to help mountain region countries and national minority areas develop processing industries and mining industries, and to carry out preliminary processing and all around use of products. The experiences in joint operation of joint enterprises of Qionglai, Dazhu, Hechuan, and Helin counties are to be summarized and promoted. In addition, vigorous development should be given various forms of rural specialized households, key households, and joint enterprise households,

support given commune member household sideline occupations, and encouragement given commune members to become prosperous through labor.

9. In order to train technicians possessed of various kinds of specialized knowledge needed in rural villages, reform of the structure of rural secondary school education has to be hastened. Most counties are to change within a period of 2 or 3 years the present general middle school system into a so-called vocational middle school (not including job assignments), and to operate upper middle school vocational classes and vocational technical courses in ordinary middle schools. After ordinary middle schools have been changed to vocational middle schools, channels for expenditures will remain unchanged under the centralized management of the educational departments, with additional payments for specialized teacher wages. Departments concerned are to organize some specialized technical personnel to serve concurrently in work positions and to teach, and to lend support in fieldwork sites and in needed experimental facilities. All departments of all industries are to operate various short term technical training classes as requirements dictate.

10. In order to fill out and strengthen commune cadre ranks where shortages exist in terms of current commune tables of organization, in addition to the three ways proposed this year by the Provincial CCP Committee (namely, 1. annual selection from among the graduates of schools specializing in farming, forestry, aquatic products, and finance and trade of a group for assignment to work in communes; 2. selection of personnel qualified to be cadres and who hold prospects for training from among those who are to replace retired cadres for transfer to communes to work for workers' wages after they have been comprehensively certified; then, after 2 years of tempering and testing, the finest being selected for promotion to cadre; 3. selection from among enterprises, institutions, and administrative units owned by all the people of a group of outstanding farming technicians and young cadres to fill the commune cadre ranks), cadres partially relieved of regular duties in communes, and outstanding party member cadres in production brigades and production teams may be selected. Following strict testing, the young and strong who are cultured, understand technology, and have definite work ability may be sent to fill up the ranks.

This document concluded by saying that if any of the foregoing regulations do not accord with documents formerly issued by the Provincial CCP Committee and provincial government, the regulations contained herein are to be applied. All levels of CCP committees and government, and all provincial level departments concerned are to prepare specific methods of implementation in accordance with the foregoing regulations and assure their implementation.

BRIEFS

LIVESTOCK PRODUCTION UP--This year the animal husbandry industry in the Xinjiang-Uighur Autonomous Region had a bumper crop. Statistics show that as of the end of June 9.5 million head of lambs and kids, foals, calves, and young camels had been born and survived, an all time high since founding of the People's Republic in the number of young livestock animals obtained. More than 34 million head of livestock were in inventory, a more than 1.5 million head increase over the last livestock industry year. This is the fifth year in which the Xinjiang animal husbandry industry had a bumper crop of livestock. [Text] [Beijing RENMIN RIBAO in Chinese 26 Jul 82 p 1] 9432

XIZANG

THREE STAGE PLAN FOR XIZANG ECONOMIC DEVELOPMENT OUTLINED

Beijing RENMIN RIBAO in Chinese 3 Aug 82 p 1

[Article: "Xizang Formulates Measures for Development of Farming and Livestock Industries to Hasten the Pace of Becoming Prospersous, Aims For a Small Change Within 3 Years, a Moderate Change in 5 years, and a Major Change in 10 Years. Continued Need to Make the Most of the Power of Policies, to Improve Production Conditions, and to Use Advanced Scientific Techniques"]

[Text] Recently the Xizang Autonomous Region CCP Committee and Autonomous Region People's Government convened a regional work conference on the rural pastoral area, which set a battle goal and specific measures to be taken for "a small change within 3 years, a moderate change within 5 years, and a major change within 10 years" to give guidance to the broad masses of peasants and herdsmen now that the problem of food and clothing has been preliminarily solved in order to make efforts to advance in depth and in breadth, to carry out economic cultural and economic construction in a planned step by step way, so that Xizang will gradually flourish and become prosperous.

The autonomous region CCP Committee raised the goal of a small change within 3 years, a moderate change within 5 years and a major change within 10 years on the basis of an idea and a demand put forward by comrades Hu Yaobang and Wan Li during an inspection trip they made to Xizang in May 1980. Following 2 years of rest and recuperation, the farming and livestock industry production of the entire region has revived and developed. The problem of food and clothing has been solved for more than 90 percent of the masses, and average per capita earnings for peasants and herdsmen amounts to 200 yuan. This provides a material foundation for guiding the peasants and herdsmen to cure poverty further and become prosperous.

The goal of one small change within 3 years is as follows: Beginning in 1980 and after 3 years of effort to make production develop after having been revived for a preliminary breaking away from poverty, average per capita earnings for peasants and herdsmen reaching 220 to 230 yuan, and average per capita earnings in 20 percent of counties, brigades and households reaching 300 yuan. The goal of moderate change is the realization of consistent development of production by the end of 1985 with a complete break away from poverty, average per capita income amounting to from 280 to 300 yuan. The idea of major change is substantial development of production by the end of 1990 with the realization of initial prosperity, average per capita earnings amounting to from 400 to 500 yuan. Specific standards were also set for the peasants' and herdsmen's food, clothing, daily use items, housing, travel, culture, education, science and technology, health, party style, civilian behavior, and spiritual civilization at different stages. On the basis of present circumstances, all prefectures, counties, communes and brigades have formulated, or are now formulating, individual goals and plans.

Acting on the basis of actual circumstances in Xizang, everybody diligently studied measures for realizing the aforestated objectives. They pointed out that henceforth substantial development will be required and, in addition to bringing further into play the power of policies, it will also be necessary to rely on improved production conditions and the adoption of advanced scientific techniques. Currently, grain yields per unit of area and per capita are below levels for the country as a whole. Though the number of livestock per capita is the highest in the country, livestock products per capita are lower, on average, than in other pastoral regions of the country. In order to change this state of affairs, while maintaining policies unchanged, it is necessary to guide peasants and herdsmen in proceeding in accordance with abilities to carry out capital construction of farming and the livestock industry, and on the foundation existing in Xizang to promote simple and useable, advanced scientific techniques with outstanding benefits.

A look back at 2 years of experiences caused everyone to emphatically note that the elimination of poverty must rely primarily on farming and the livestock industry, and that becoming prosperous will require, to a very large extent, reliance on economic diversification. Xizang has a large area and numerous resources, yet the utilization rate is the lowest in the country, and it is a place in which tremendous potential for development exists.

'SET BASE PROCUREMENT FIGURE' SYSTEM EXPLAINED

Beijing NONGGUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 8, Aug 82 pp 42, 43

[Article by Zhejiang Provincial Agricultural Commission Office: "Accurately Set Base Procurement Figures to Advance Development of Production"]

[Text] Zhejiang Province's natural resources for agriculture are plentiful and rural economic diversification is well developed. It is an integrated agricultural region. Presently procurement consists principally of agricultural and sideline products with the institution of "accurately set base procurement figures" guaranteed to remain unchanged for several years, output in excess of quotas being divided between state procurement and retention by producers with bonuses being given for excess procurement, (which will be termed "fixed base figures" below).

Why The Need For Fixed Base Figures

It is fully necessary for the state to carry out state requisition procurement and assigned procurement policies for major agricultural and sideline products. However in the procurement of Category II agricultural and sideline products, there has been stifling centralization and over regulation, the more produced, the more procured and the more shipped, producers lacking self-determination in controlling a portion of the agricultural and sideline products and finding it difficult to use left-over products for development of processing industries. This has hurt the peasant's legitimate economic interests and stifled peasant initiative for development of commodity production.

Following the Third Plenary Session [of the 11th Party Central Committee], the Central Committee took a series of actions to effect major readjustment of agricultural policies. In pursuit of a program of "emancipation of thinking, liberalization of policies, and enlivening the economy," Zhejiang Province summarized the lessons of experience in procurement of agricultural and sideline products, and gained enlightenment from the practice of fixed base figures in the procurement of grain, cotton, and oil-bearing crops. Then, following the spirit of taking the national economy as the key link with market regulation being supplementary, giving concurrent concern to the welfare of the country, the collective, and commune members, looking after both production area and marketing area, rural and urban needs, and following discussion and study with sectors concerned, the provincial government approved institution, beginning in 1980, of "fixed base figures" for 14 kinds of Category II agricultural and sideline products including tea, citrus fruits, mat straw, Catalpa timber, Chinese tallow tree seeds, rosin, raw lacquer, and aquatic products.

How Base Figures Are Set

The main points of the "fixed base figures" that Zhejiang Province instituted for 14 kinds of Category II agricultural and sideline products were as follows:

First, a well defined guiding thought on "fixed base figure" to ensure fulfillment of state quotas. "Fixed base figures" are, in reality, assigned procurement. Their basic point of departure is: no decline in existing state procurement levels, but increases still being possible; guaranteeing commune and brigade self-determination in the handling of products remaining after fulfillment of state prescribed sales quotas so that the peasants will be able to gain concrete benefits from efforts to increase production. Depending on different circumstances for different products, the base figures to be set for some will be either average actual procurement last year or for the past several years, while for others quotas will be set on the basis of calculation of proportional procurement by the state and retention by producers of average quantities for the present year or for the past several years, guaranteed not to change for several years. For example, tea, is a major special product of the province and also has traditionally been a major export item. In 1979 it accounted for one-fourth of the national output and the quantity purchased by the state, and for 30 percent of the national quantity exported. In a trial run of "set base procurement figures, division of production in excess of quota and reduction of taxes on excess procurement, giving up some profit," the base figure used was actual procurement in 1978, the province implementing these figures echelon by echelon to the counties, communes, and production brigades, no change guaranteed for 5 years. Tea produced in excess of base figures was divided up 60-40, i.e., 60 percent was procured under state plan, and 40 percent was under the control of communes and brigades. The portion under control of communes and brigades could be marketed freely or arrangements made to send it to other provinces; alternately it could also be sold to the state.

Second was to permit peasants to gain more benefits from increases in production and sales in excess of quotas. The main way in which this was done was as follows: One was to reduce taxes by giving up some profit. In the case of tea, for example, the portion that was a part of base figures was purchased at list price. The portion in excess of base figures could be sold to the state (as unfired tea leaf) at a reduced tax rate, the state tea plants giving up some of their profits thereby. As a benefit of the reduction in taxes, the 30 percent increase over list price for spring tea, and the 25 percent increase for summer and autumn tea was paid directly to producing units with no additional bonuses being given. For the portion of profits given up, 70 percent of state tea plant processing profits were rebated to tea producing counties that had exceeded base figures for their use in developing tea production. Second was purchase at negotiated prices of amounts in excess of base figures. Provincial level departments in charge centrally set fluctuating prices, maximum ceiling prices and maximum floor prices for different individual products on the basis of stable price policies. Third was the use of two kinds of prices. By this is meant that a certain proportion from within assigned quotas was designated for procurement at subsidized price or negotiated price. In the case of Chinese tallow tree seeds (or Chinese tallow oil), for example, no matter the quantities purchased, and irrespective of collective or state farm distinctions, one-half of the actual amount offered for sale was purchased at list price and one-half was purchased at a subsidized price. Fourth was assistance funds given for production. For sugarcane, for example, for every dan purchased at the prevailing average price of 2.25 yuan, 0.45 yuan in assistance funds was given for production to be paid by sugar mills at the time of purchase. The problem of a source of funds for this purpose was solved through the transfer of industrial and commercial profits and reduction or exemption from industrial and commercial taxes.

Third, appropriate readjustment of market management was done. The provincial government issued instructions for the readjustment of agricultural and sideline product market management classification tables and limitations on negotiated purchases and negotiated sales requiring that except for silkworm cocoons, cowhides and such industrial raw materials, all other Category II agricultural and sideline products could, following producer unit fulfillment of quotas, be sent to market for individual or joint marketing, could be processed by producers for the development of agriculture, industry, and commerce, or could be consigned to commercial departments to act as procurement and marketing agents. It was stipulated that until such time as any given commune (or state farm) had completed its quotas for citrus fruits, none could be sent to market. However, once any given commune (or state farm) had fulfilled individual unit quotas for individual varieties, as attested by issuance of certification by the local supply and marketing cooperative, it had the right to sell individually or to organize joint sales, had the right to undertake processing, or to arrange with the supply and marketing cooperative for purchases and sales at negotiated prices, or have the supply and marketing cooperative act as agent in purchase and sales.

Outstanding Results After Two Years of Implementation

Practice has shown that following "set base figures", not only was fulfillment of state procurement and upward assignment quotas guaranteed, but the interests of local areas, communes and brigades, and peasants were looked after for advancement of the development of production. Specific benefits were as follows:

First, promotion of the development of production. Comparison of 1981 with 1979 shows an 80,000 mu increase in the silkworm mulberry area in the province and a 13 percent rise in silkworm cocoon output; a 150,000 mu increase in the tea growing area and a 33.8 percent increase in output; a 140,000 mu increase in the citrus growing area, a 270,000 mu increase in the jute growing area, and a respective 22 and 6.5 percent increase in output in 1981 as compared to 1980. Increases also occurred in the afforested area, in moso bamboo reserves, in tung seeds, Chinese tallow tree seeds, and freshwater fish.

Second was assured state procurements. Following "fixed base figures," except in the case of individual varieties, the procurement quotas handed down by the province were all overfulfilled. During the first year, the total value of agricultural and sideline products purchased by the supply and marketing system increased 5.3 percent to reach 1.27 billion yuan. This included procurement of 1.23 million dan of silkworm cocoons, an 11.8 percent increase and 23 percent more than base figures; and 1.35 million dan of tea, an 11.8 percent increase and 22.7 percent more than base figure. Last year was the second year of "fixed base figures," and the province overfulfilled, a whole month ahead of schedule, its procurement quotas for the year as a whole, the total procurement figures increasing by another 10.3 percent. This included procurement of 1,554,000 dan of tea, 454,700 dan over the base figure; and 1.24 million dan of silkworm cocoons, 240,000 dan more than the base figure. As a result of increase in quantities purchased, the supply requirements of light and textile industries, the foreign export trade, and markets were substantially assured.

Third was increase in peasant income. Statistics for 2 years on "fixed base figures" for five kinds of tea show that after fulfilling base figures, the added price peasants obtained from the sale of quantities in excess of base figures was 46.27 million yuan. The added price peasants obtained from base figures for 14 kinds of products amounted to approximately 100 million yuan. If benefits obtained from individual marketing or processing of products following fulfillment of base figures is added to this, increased peasant earnings amount to more than 150 million yuan. Despite two consecutive years of decrease in grain output in Zhejiang Province as a result of disasters, the number of brigades in which per capita earnings from the collective averaged more than 300 yuan still rose from 129 in 1979 to 660 in 1981 (not including marine fishing industry production brigades).

Fourth, it increased state earnings. Statistics on the province's tea, cotton, silkworm cocoons, sugarcane, and jute show that over a 2 year period state tax revenues from the portion procured in excess of base figures amounted to 102.82 million yuan and industrial profits amounted to 95.55 million yuan for a total increase in earnings of 198.37 million yuan. Increased price payments amounted to only 75.03 million yuan, however, or only 37.82 percent of national earnings.

In short, results have been outstanding from 2 years of implementation of "fixed base figures." This method should gradually become a basic method for embodying the principle of taking the planned economy as the key link with market regulation being supplementary in the procurement of agricultural and sideline products.

LIVESTOCK FEED PRODUCTION REPORTED GREATLY INCREASED

Beijing ZHONGGUO CAIMAO BAO in Chinese 3 Aug 82 p 2

[Article: "Zhejiang Province Energetically Develops Livestock Feed Processing Industry; Plans Building of 120 Plants in 3 Years For a Livestock Feed Processing Capacity of 1 Billion Jin"]

[Text] Zhejiang Province, one of the major hog raising centers of the country, is gradually building a livestock feed processing industry system. The province is preparing to build 120 livestock feed plants between now and 1984, increasing to 1 billion jin its livestock feed production capacity.

The provincewide livestock feed work conference recently convened by the Provincial Food Department made specific arrangements for implementation of this year's plant building plans. Full use is to be made of surplus plant buildings and equipment at existing grain and oil processing plants, and the path of tapping potential, restructuring, and improving is to be taken in carrying out expansion and improvements. An overwhelming majority of the 60 plants planned for this year will be completed and go into production this year.

Zhejiang Province annually uses more than 3 billion jin of grain as livestock feed. In raising hogs, in addition to the use of proper amounts of coarse green fodder, the peasants have always used mostly grains for livestock feed. Particularly in prefectures like Jiaxing and Jinhua, which are major rice producing areas, and where little other grain is grown, the peasants mostly feed rice to their hogs. This feeding method wastes a lot of grain, is costly, does not provide complete nutrition, requires a long feeding period, and wastes both labor and firewood.

In order to change this peasant feeding method and promote development of hog production, the Provincial People's Government has adopted numerous measures during the past 2 or 3 years, and has vigorously increased production and promotion of the use of blended livestock feeds and mixed livestock feeds. Province provided funds for investment in development of the livestock feed industry for the period 1979 to 1981 amounted to 5.8 million yuan for the building of 40 livestock feed plants. As of now, 25 of these plants have been constructed. Each of these plants makes full use of silkworm chrysalises, fish meal, bone meal, powdered blood, rapeseed cake, cottonseed cake, and such protein resources to produce blended feeds and mixed feeds. Last year production increased to 400 million jin, and this year it is expected to rise to 500 million jin. In addition to assuring state award sales, the product of these plants, which uses corn to make blended and mixed livestock feeds, is traded with the peasants for rice. During the last half of last year alone, the province took in more than 50 million jin of paddy in exchanges. Not only was hog production promoted, but national storage of paddy was augmented.

RUNNING WATER PROVIDED TO SELECTED RURAL AREAS

Beijing RENMIN RIBAO in Chinese 26 Jul 82 p 1

[Article: "More Than 3 Million Peasants in Zhejiang Province Served By Running Water; More Than 3,900 Running Water Plants Built in Rural Villages"]

[Text] Zhejiang Province has built more than 3,900 rural running water plants, and more than 3.5 million peasants are users of clean, sanitary running water.

Rural villages in Zhejiang Province have always used mostly river and pond water for drinking, but water quality was poor and pollution serious. The masses urgently demanded improvement in drinking water conditions. Provincial Governor Li Fengping [2621 0023 1627] and Vice Governor Liu Yifu [0491 0076 1133] went into rural villages on several occasions, going to places where drinking water conditions were poor and the incidence of disease high to gain an understanding of conditions, obtain firsthand data, and direct water improvement work. Ever since last year, many counties and cities including Ningbo, Jiaxing, Jinhua and Hangzhou established water improvement leadership teams, putting in place personnel, technology, materials, and operating expenses.

Virtually all of the funds required for providing running water and improving drinking water sanitation in rural Zhejiang were contributed by commune and brigade collectives and the masses of commune members.

The use of running water in rural villages has reduced the incidence of communicable diseases and improved commune member household environmental sanitation and individual sanitation, improving the physical health of the broad masses of commune members.

TITLE: "Study of Physiological Races of Wheat Leaf Rust Mycorrhizae in Shanxi Province"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 8, 1982 pp 12-14

ABSTRACT: Wheat leaf rust tended to spread in spring and winter wheat planting areas of Shanxi Province; crop failure resulted in certain years. The mycorrhiza can winter and summer in the province so as to complete the yearlong infection cycle. The earlier the fall sowing, the earlier is the outbreak of infection and the more severe for the crop infection. At present, very few wheat varieties have resistance against this leaf rust; therefore, selective breeding of such varieties with resistance to lead rust and high yield is important to plant protection.

After years of study, Yezhong No 1, No 2 and No 3, as well as Leixing No 11 physiological races were identified as the source of infection. The paper describes the bacterial culture and isolation. Inoculations with mycorrhizae were conducted in recent years to obtain relatively good-resistance wheat varieties, such as the Luofulin No 10 and No 13, the Shanqianmai, the Gaojiasuo, and the

[continuation of SHANXI NONGYE KEXUE No 8, 1982 pp 12-14]

Zhongwu; these varieties can be used as resistance parental pairs for selective breeding.

TITLE: "A Preliminary Genetic Study on Growth Period in F_1 of Hybrid Rice of O. Sativa Subspecies Keng"

SOURCE: Beijing YICHUAN [HEREDITAS] in Chinese No 4, 1982 pp 5-7

ABSTRACT: Breakthroughs with hybrid Keng subspecies were reached in Liaoning, Beijing, Xinjiang and Yunnan; these subspecies are mostly early-ripening Keng subspecies. The growth periods were markedly shortened to 105-110 days after these subspecies were introduced into southern Zhejiang, from 156 days in Liaoning in the case of the Fengjin/C57 rice variety. The shortened growth period leads to a reduction in the sprouting number of seedlings and small spike types, as well as lack of growth vitality. Therefore, in the south of China the selective breeding of subspecies Keng should first solve the problem of growth period. The paper describes the observation of full spike growth (in days) as well as the relationship between spike sprouting days and number of spikes with and without natural lighting in greenhouse cultivation. Higher hybrid vitality can be obtained by cross breeding of restoration varieties (with the appropriate growth period) with a sterile variety of late- or medium-ripening Keng subspecies

[continuation of YICHUAN No 4, 1982 pp 5-7]

suitable to local cultivation. A certain photosensitivity of the rice variety is required to grow in Zhejiang Province. Included are five figures and one table. The authors express their gratitude to associate professor GAO Mingwei [7559 2494 1414] of Zhejiang Agricultural University for his counsel.

TITLE: "Effects of Different Genotypes on Induction Frequency in Anther and Scutellum Culture of Maize in Vitro"

SOURCE: Beijing YICHUAN [HEREDITAS] in Chinese No 4, 1982 pp 8-10

ABSTRACT: In recent years, spurred by progress in maize cell and tissue culture, maize improvement has been sought with the cell and tissue manipulation. In 1975, it was reported that the Institute of Botany of the Chinese Academy of Sciences obtained, for the first time, pollen-bearing maize stalks. Later in 1979 and 1980, Chinese researchers began the hybrid breeding of maize from pollen culture. These reports mentioned that the genotypes are related to the induction and induction frequency. The paper reports the preliminary results on maize culture in vitro for inducing the growth of maize stalks from cells. In the low humidity environment of Northwest China, the authors succeeded in transplanting maize stalks with the blending of sand, loam and sawdust after initial failure. Included are three tables and four photographs.

TITLE: "Agroclimatic Classification at the County Level by Use of Meteorological Yield Data"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 7, 1982 pp 11-12

ABSTRACT: The authors processed meteorological yield data by using three methods: natural normalized solution, indistinct grouping analysis, and Euler's distance analysis. The following results were obtained: the first and second characteristic vector distributions by using natural normalized solution, and other results by use of the other analyses. An electronic computer was employed in classifying meteorological yield data; several methods of classification were compared to find a feasible and sound plan. The indistinct grouping analysis and Euler's distance analysis have generally similar outcomes; calculations are simple and analysis is intuitional in the former method, but occasionally grouping may not be attained. In the method of natural normalized solution, the meteorological yield is considered as a kind of time-space distribution field with certain agroclimatic significance and good convergence. Among the characteristic vectors of the main characteristic values, relatively ideal distribution can be selected. In addition, the time components obtained can be used for the classification of high

[continuation of QIXIANG No 7, 1982 pp 11-12]

and low yield years, as well as for agroclimatic analysis and harvest forecasting. However, an electronic computer should be used because the volume of calculation is quite high.

TITLE: "The Use of Wind Energy as a Driving Force for Irrigation"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 7, 1982 pp 16-17

ABSTRACT: The paper discusses the application of wind energy for the irrigation of paddy field in Jiangsu Province. Three terms are introduced: shart-up wind velocity, cutoff wind velocity and designed wind velocity. The start-up and cutoff wind velocities are, respectively, 3 and 20 meters per second, since the wind wheel will not turn at lower than 3 m/sec and the wheel will be made to stop turning at more than 20 m/sec of wind velocity, to avoid damaging the installation. The main types of wind wheels in the province are from 6 to 7.5 meters in diameter, with a wind utilization index ranging from 0.18 to 0.35. Mathematical formulas are presented to derive data for wind energy, amount of water lifted, and number of mu to be irrigated. One of two tables lists the amount of water lifted and the number of mu irrigated for lifting water 1, 2 and 3 meters in Dafeng County for the early-, medium-, and late-ripening rice varieties. Rainfall is also taken into account in the calculation.

I. GENERAL INFORMATION

CONFERENCES ON AGRICULTURAL ECONOMY HELD

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 7, 1982, pp 47-56

[Article: "Discussion on How Agriculture Can Put Into Effect a Program of 'Taking a Planned Economy as the Key Link With Market Regulation Being Supplementary'; Chinese Agricultural Economics Society Convenes Beijing Region Academic Discussion Meeting"]

[Text] On 20 April and again on 14 May, the Chinese Agricultural Economics Society held two Beijing area academic discussion meetings, which discussed how agriculture can carry into effect a program that "takes a planned economy as the key link with market regulation being supplementary." Excerpted remarks of some comrades at the meeting are published below.

Liang Xiufeng [2733 4423 1496] (Economics Institute, State Statistical Commission): How should more than 30 years of agricultural planning work in China be evaluated? Practice is the sole criterion for judging truth. In a situation of large population relative to available land, we substantially solved the food and clothing problem for 1 billion people. This is a tremendous achievements in China's economic construction, and it is also a tremendous achievement in the development of agriculture. Therefore, in an overall sense, China's agricultural planning work has scored very great achievements. However, it has gone through a tortuous course.

Beneficial experiences in China's agricultural planning have been the following:

1. It has proceeded from China's realities, with emphasis on the analysis and study of conditions for development of agriculture (production relationships. production forces, and the superstructure) to set workable agricultural development goals and speed of development. For example, in formulating the first five year plan, we adopted an attitude of comparatively seeking truth in facts, and after mastering a large amount of data, we diligently summarized and analyzed major pertinent factors and realized that for some time in the future. China's speed of agricultural development could generally be no greater than four or five percent, and that speed of grain development could generally be no more than three or four percent. Third years practice has demonstrated that the results of such an attitude, methods and analysis in studying and planning were appropriate.

2. Conscientious implementation of the guiding mentality of taking agriculture as the foundation and shifting the work of economic departments to the track of taking agriculture as the foundation. On the one hand we arranged

the speed of economic development and the scale of national construction, making sure they corresponded to the ability of agriculture to bear them. On the other hand, in the distribution of manpower, material, and financial resources, we first insured the needs of agricultural development.

3. In order to assure basic agricultural products needed for national economic development, we adopted measures for the implementation of planned procurement (centralized procurement) of major agricultural products, which were supplemented by grain award sales and reward price policies. These both placed specific demands on the development of agriculture and the distribution of agricultural products, placing them on the track of state plan, and by and large assured normal economic life and the basic stability of market prices.

4. Attention to requirements of the laws of value in terms of the economic development situation, with planned appropriate readjustment of purchase prices paid for agricultural products and a gradually reduction in the price "scissors" between industrial and agricultural products to promote agricultural development.

5. Formulation of agricultural plans and organization of the realization of agricultural plans. Attention was given both to agricultural product procurement policies, agricultural procurement price policies, agricultural investment policies, rural loan policies, and agricultural means of production supply policies, and the linking of various kinds of organizational work, technical work, and ideological and political work to assure plan implementation and fulfillment.

The main problems in China's agricultural planning work are as follows:

1. Generally overly high agricultural production quotas. In most years, major tasks for the year have not been fulfilled.

A look at the four big production quotas for grain, cotton, oil-bearing crops and live hogs shows that for more than half the years, annual plan tasks for grain and live hogs were not fulfilled. For cotton and oil-bearing crops, in about three-fourths of the years, annual plan tasks were not fulfilled.

2. Insufficient unified planning with due consideration for all concerned, and comprehensive arrangements in agricultural plans. Principally in the relationships among production, construction, and daily life, and among the country, the collective and commune members, in most years handling was not sufficiently satisfactory. In some years production developed and construction expanded, but peasant living standards did not improve. In some periods state purchase tasks were inequitable and burdens were overly heavy to the serious impairment of peasant enthusiasm for production. In some periods, output of farm products increased, but fulfillment of farm product state purchase plans and allocation plans was poor to the detriment of national economic construction.

3. Equitable use and protection of agricultural resources has been done poorly causing a deterioration in basic conditions for agricultural production and imbalance in the natural ecological environment, which bring in their wake serious consequences for development of agricultural production.

4. In the direction of agricultural development, failure sometimes to give attention to the principle of adaptation of general methods to local situations with excessive and stifling control; at other times a loosening of plan guidance and a tendency toward development of liberalism. The former was a major tendency in the past; the latter is a major tendency now.

The several principles that should be adhered to in future agricultural planning work are as follows:

1. Ours is a socialist country in which development of agriculture must be done under the direction of unified national plans with implementation of a program in which the planned economy is paramount and market regulation supplementary.

2. Specific forms and specific content of agricultural plan management will differ in accordance with different times and different circumstances. China's agricultural production circumstances have determined that adoption of overly concentrated management methods are not suited to agriculture. At the same time, in order to assure both the needs of the people's daily lives and economic stability, it is necessary to institute vigorous plan management over production and procurement of certain major agricultural products.

3. Improvement and strengthening of agricultural product procurement plans, correctly handling relations among the country, the collective and commune members. For major agricultural products in extremely short supply, it is necessary to formulate state purchase quotas that must be fulfilled. Base figures for state purchases may not decline further, and the proportion purchased at negotiated prices cannot increase further. For major agricultural products for which supply is temporarily greater than needs, maximum procurement limits should also be properly set in accordance with actual circumstances. In addition, one must realize that, in an overall sense, agricultural products in China are never enough. One should not, upon seeing a temporary increase, proceed to institute senseless excessive restrictions.

4. In grain production, under no circumstances can there be a slackening of leadership, and is necessary, at the same time, to give attention to development of economic diversification. As regards the problem of how to control the grainfield area, this must be linked to production plans and state procurement quotas.

Zheng Linzhuang [6774 2651 5445] (Beijing Municipal Agricultural Economics Society): Let me give you a briefing on some discussions of the Beijing Municipal Agricultural Economics Academic Discussion Exchange Meeting on the applciation to agriculture of putting into effect a program of "taking a planned economy as the key link with market regulation being supplementary."

1. On the issue of agriculture plan

(1) Though socialist public ownership provides conditions for the possibility of instituting a planned economy, in order to translate the possibility into reality, it is necessary to act on the basis of agricultural production characteristics so that plans are truly established on a scientific foundation. First of all the circumstances have to be understood, and all data pertinent to agricultural production, requirements, transportation and marketing, etc. have to be understood. In order to achieve this goal, not only is it necessary to understand agricultural circumstances per se, but also to understand other economic areas related to agriculture, and even circumstances in the political and social realms. Not only is it necessary to refer to present and past circumstances in formulating plans, but it is also necessary to make scientific forecasts about circumstances that may crop up during the period of time when the plan is in operation, using these as parameters to formulate plans. Secondly, during the period of operation of the plan, it is necessary to make changes in plans that are commensurate with changes in circumstances. Not only in agricultural production plans, but also in plans for procurement of agricultural products, for agricultural loans, for the agricultural means of production, etc., it is necessary to make corresponding changes. Some comrades have noted that for agricultural plans to be scientific, the following work has to be done: There has to be a correct guiding mentality; good zoning of the agricultural economy on the basis of surveys and studies; an overall balance of manpower, financial, and material resources, and of supply, production, and marketing; and good forecasting work.

(2) On the issue of plan quotas. Some comrades suppose that our agricultural economy is a collective economy collectively owned by the laboring peasants, that profits and losses from operations are the responsibility of commune members, and that commune members have the right to distribute their own products. Thus, in carrying out plans, it is necessary to give communes and brigades fairly great self-determination, and plans of a command nature may not be implemented. Some other comrades believe that crops such as grain, oil, and cotton are major products closely related to the national economy for which direct plans of a command nature should be instituted to assure sufficient output to satisfy the needs of economic development and the people's livelihood. For the production and marketing of ordinary crops, indirect plans that are in the nature of guidelines may be instituted. In the institution of plans in the nature of guidelines, numerous comrades noted that general use of an agreement system is a workable method. Some comrades pointed out that with institution of an agreements system stifling regulation and binding producers hand and foot cannot take place.

For example, in the production of varieties, one need only stipulate the amount of a major category (as for example grain); there is no need to specify amounts of each and every variety (such as rice, wheat, corn, gaoliang, etc).

Some comrades said that frequently when growing area quotas were handed down, it was not possible to attain the goal of assured output. Today we can only require of agriculture that it provide required amounts of commodity products; consequently, it is enough to hand down procurement quotas for major commodity products (such as cotton, grain, and edible oil). As to how to fulfill quotas, let production units decide themselves on the basis of their own actual circumstances. Still other comrades pointed out that in a situation in which prices for agricultural products cannot move, and in which economic regulatory methods such as revenues and loans are not complete, if plan goals are to be guaranteed fulfillment, it is certainly necessary to employ controls over growing areas, otherwise plans could come to naught.

(3) On the issue of the planning system. Delegates to the meeting unanimously pointed out that at the outset our agricultural planning system was an imitation of the Soviet model, but that during the past 30 years many important lessons of experience have been learned through practice. It is on the basis of these lessons of experience that reform of the prevailing agricultural planning system must be carried out. Some comrades noted that a look at the experiences of other countries that practice planned economy shows that the general tendency in reform of agricultural planning systems is for the state to liberalize direct control of a command nature in a gradual transition to indirect planning. Reform of China's planning system should also adopt this orientation. This means the gradual liberalization of state interference requiring full use, in accordance with economic laws, of the economic levers of prices, revenues, and loans to regulate the agricultural economy. Thus, reform of the agricultural planning system requires first of all a perfection of state plan regulatory methods. Currently prices, revenues, loans, economic legislation, agreements, and such economic methods in the country's agriculture are still very imperfect. Under these circumstances, we not only have to study what is the best system to adopt under any given condition, but we also have to study the problem of how to make the transition from the original system to the new system.

2. On the issue of market regulation

(1) Comrades attending the meeting affirmed, first of all, that so long as the commodity economy exists during the period of socialism, the relationship among production, laws of value, and currency will still play a role. Therefore, market regulation has to be used to give impetus to the development of the socialist economy.

(2) The central issue in market regulation is how to use prices to effect regulation, which means, in fact, price regulation. The greatest problem in China's use of the method of "market regulation" in agriculture is that the various price proportions have been set very inequitably, and prices have not been readjusted promptly on the basis of changing circumstances.

Bao Yongjiang [0545 3057 3068] (Economics Institute, Tianjin Municipal Academy of Social Sciences): Formerly agricultural planning work was centralized to death. Everyone is familiar with "arbitrary uniformity" and such shortcomings. During the past several years following the gradual enlivening of the rural economy, some problems also cropped up in agricultural planning, principally loss of control. As manifested in production, actual production frequently has had nothing to do with plan arrangements. For example, flue-cured tobacco growing area increased, but production of crops for which costs were high and profits low (particularly the grain growing area) decreased. As manifested in the realm of circulation, production and marketing were frequently out of kilter. Overstocking occurred for products for which markets had small capacity (such as rapeseeds or edible sunflower seeds) while some commodities in extremely short supply (such as eggs, and fish) could not be bought at time. People do not hold identical views on these situations.

Some people supposed that this was the peasant's "liberalization trend," specifically manifested in "great work when profits are great, little work when profits are small, and no work when there is no profit," and that the solution lay in future strengthening of "planned regulation," with "planned regulation" meaning, "You arrange production as I say, and you sell as I say," and there is no other way than this.

We want to ask, just why did loss of control occur during the past several years? I believe there are three reasons:

1. Improper regulatory measures that could not meet the needs of the commodity economy under the two market conditions of development of a diverse ownership structure and two kinds of prices. No matter whether in the collective economy or the privately retained economy, except for the portion for self-sufficiency in consumption, peasant development of production and participation in exchange is done for the purpose of gaining commodity value as a way of making a living and a means of getting wealthy. The various actions we have taken since the Third Plenary Session of the 11th Party Central Committee to enliven the rural economy have been, in fact, a recognition of the necessity of looking after the peasants' economic welfare. Nevertheless, many of our specific policies did not suit these circumstances and were promptly changed. To take hog and egg production in Tianjin, for example, regulations prohibiting or limiting the raising of hogs and chickens were abolished and farmers' markets liberalized, yet in award sales policies for procurement, some of the former regulations on separate treatment of the collective economy and the privately retained economy or even bias against the privately retained economy were still maintained. For example, for evey jin of hen's eggs peasants sold, they were allowed an award sale of 1 jin of grain and payment of 1 yuan, and for every 200 jin hog they sold, they were allowed an award sale of 250 jin of grain. When collectives sold 1 jin of hen's eggs, they got 3 jin of grain and payment of 1.16 yuan, and when they sold a 200 jin hog, they got an award sale of 415 jin of grain plus an 8 yuan subsidy. When state farms sold 1 jin of hen's eggs, the award sale of grain was 4 jin and 1.16 yuan was paid; when they sold a 200 jin hog, the award sale of grain was 790 jin, and they got an additional 8 yuan subsidy. Some articles rebuked rural communes and brigades for not producing and not wanting the produce farm products on which they lost money. I believe we ought to check up on our regulatory functions to find out why regulatory action cannot be taken to solve this problem with losing money?

2. Organizationally, as a result of the separation of departments, mutual wrangling frequently occurs, efficiency in getting things done is low, and ability to regulate is poor. Take the development of households specialized in the raising of livestock, for example. In the spring of 1981, the Tianjin CCP Committee made various specific regulations, yet because of the large numbers of departments involved plus lack of common understanding, many actions were delayed and could not be implemented. The former regulation allowing the borrowing of ripe grain during the time chickens were growing to maturity, the grain being deducted when egg deliveries were subsequently made was revoked (and most recently restored); supplies of young chicks, mixed feeds, and poultry medicines were intermittent, and some places refused to sign marketing agreements with specialized households, and refused to provide grain or money subsidies in accordance with regulations. In consequence, quite a number of specialized households faultered. Thus, when the time came for new chickens to produce eggs (the slack season in egg production), we tried to get them to make deliveries and to sign contracts, but quite a few specialized households refused. They took their eggs to farmers markets and sold them. Who is to blame for this?

3. Imbalances in the production structure, steady deterioration of the farmland ecological system, rising costs in agriculture, increasing investment, and frequently creeping decline in output and earnings. Some published materials blamed communes and brigades for not wanting to invest in the capital construction of their vegetable gardens when the fact was that the area reserved for vegetable growing in Tianjin had been cut back. Survey shows that gross income from Tianjin vegetable fields averages 318.50 yuan per mu, and net income averages 154,000 yuan per mu.[1] Cost of plastic enclosures runs to 1,304.68 yuan per mu and earnings are 1,465 yuan, net earnings being only 160.32 yuan.[2] The additional investment is not matched by additional income. Vegetable output for the city as a whole averaged 5,676 jin per mu in 1957; in 1980, it was 6,503 jin for an increase of only 11.5 percent. This shows that during the past 2 or 3 years, we have not been able to help peasants increase production. Under these circumstances, if the peasants do not want to increase investment in order to develop production on lands reserved for the growing of vegetables, who is to blame?

1. Data provided by Non-staple Food Department, Municipal Agricultural Commission

2. According to a survey done at Third Production Team, Hezhuang Brigade, Shuanggang Commune in the southern suburbs.

How can the principle of taking the planned economy as the key link with market regulation being supplementary be carried into effect? Some comrades simplistically suppose that plant regulation means "listen to me," and that market regulation means "listen to you." By proceeding from this notion, recently a situation of "arbitrary uniformity" that takes no account of peasant interests has again emerged in assigned procurement and assigned livestock raising work. For example, for close-in suburbs having no private plots that normally eat commodity grain, vegetable garden brigade commune members having an average of only one-tenth of vegetable fields were also required by regulations to raise one chicken and assigned a quota of 3 jin of eggs. These brigades had never had assigned procurement quotas in the past, and each household raised an average of three to five chickens, depending mostly on the personal grain rations provided by the province to feed their chickens, using egg production to improve their lives. Now, with the institution of an assigned quota whereby an award sale of 1 jin of grain is made for each jin of eggs sold to the state, this amounts to each household being required to deduct 40 jin from its grain ration annually. The result has been only to make this group of commune members even less willing to raise chickens, and to buy eggs for money or else trade grain coupons on the black market in exchange for eggs to eat, thereby increasing pressure on society's egg supplies. Therefore, to regard planned regulation simplistically can only cause the agricultural economy to regress to a vicious cycle of "death from centralization and chaos from liberalization."

Agricultural planning is a science. Planned economy requires taking account of the fundamental characteristics of the country's agricultural economy. I believe that the principle of taking the planned economy as the key link with market regulation being supplementary must be carried forward on the existing foundation with no regression to the former predicament of "high centralization and low effectiveness." Therefore, realization of planning of the agricultural economy means first of all, science (doing things in accordance with objective natural laws and economic laws); second, concurrent concern (for the interests of the country, collectives, and commune members); and third, support (communes, brigades, and peasants developing production, increasing commodities, and increasing income).

For the moment, for some agricultural and sideline products (such as grain, cotton, and oil-bearing crops) in extremely short supply and that bear on the national economy and the people's livelihood, the handing down of quotas in the nature of commands, and the institution of state requisition procurement centralized procurement, and assigned procurement is entirely necessary. However, one should not regard this as the sole way in which to have a planned economy, much less should one treat it as a set national policy to be ensconced for a long period of time. Looked at in long range terms, quotas that are in the nature of commands, centralized procurement, state requisition procurement, and assigned procurement are not the optimum policies. A desirable method is use of the contracts system and institution of soft planning, by which is meant state control of pre-production and post-production departments, signing agreements with the peasants to provide all around service and for production and marketing, using help to the peasants in increasing output and increasing earnings to put all or a large part of products on the state plan market track. This is also the form that the peasants are most willing to accept. It has five characteristics as follows: (1) plan quotas are made scientific; (2) there are no quotas in the nature of commands; (3) supply, production, and marketing, and manpower, financial and material resources are part of an integrated whole; (4) it increases output and earnings; (5) production and circulation of commodities are handled according to plan on the basis of voluntary peasant participation.

Yu Guoyao [0151 0948 5069] and Li Bingkun [2621 3521 0981], (former Ministry of Agriculture Policy Research Office): A prominent problem in the development of agriculture today is that the growing area for some crops does not conform to state plans. For example earnings from economic crops are currently far higher than earnings for grain crops. The peasants do not want to grow grain, but would rather enlarge the economic crop growing area.

Why has such a situation come about? Some comrades believe it was caused largely by peasant liberalized planting following institution of agricultural production systems of responsibility. We feel the problem should not be regarded in this way. China's economy is a socialist planned economy in nature in which the power to set prices is in the hands of the state, and authority over procurement and marketing of major agricultural and sideline products is also, to an overwhelming extent, in the hands of the state. The peasants simply do not have at hand the necessary conditions for liberalized planting. The fundamental reason for the lack of conformity lies in our planning work not having been complete, and in the not very adept use made of prices and such economic levers, and of legal standards to bring about internal balance within agricultural production. For example, within agricultural products today, no equitable price parities have been set that are capable of maintaining balanced development of agriculture; rather ad hoc action is taken to treat headaches when headaches occur and treat aching feet when aching feet occur. When rapeseed and flue-cured tobacco procurement quantities did not increase, tremendous increases in procurement prices caused net benefits derived from the growing of rapeseed and flue-cured tobacco to soar above net benefits from the growing of other crops, particularly net benefits from the growing of grain. This caused the present situation in which the grain growing area cannot be stabilized and the rapeseed and flue-cured tobacco growing area cannot be controlled.

In light of the foregoing situation, commensurate action has to be taken to strengthen planning guidance so that the entire agricultural economy develops harmoniously in accordance with the objective requirements of the basic socialist economic laws. We believe that strengthening of plan guidance for agricultural development requires efforts in several directions, but that most important is doing a good job of the following two tasks:

First establishing and maintaining fairly equitable internal price parities for agricultural products. Inequitable internal price parities for agricultural products has been a longstanding problem in China's agricultural development, and it is also the major reason for the lack of conformity that has taken place in agricultural development during the past 2 years. In order to maintain harmonious development of China's agricultural production, it is necessary first of all to establish an equitable internal price parity for agricultural products. What is an equitable internal price parity for agricultural goods. Generally speaking, an equitable internal price parity for agricultural products is commensurate with the proportional amount of various among various agricultural products. Yet another indicator that reflects whether or not internal price parities for agricultural products are equitable is whether the overall equivalent amount of labor invested in different agricultural products is able to obtain overall equivalent net earnings. Naturally under circumstances in which a certain agricultural product is in seriously short supply or requires special support, within a given period of time to cause, in a planned way, earnings from production of these products to be higher than from the production of other farm products in order to stimulate production of these farm products in order to achieve balance between supply and demand is also equitable. However, such a state of affairs should not be maintained fixed and unchanged for long. Rather proper readjustments should be made on the basis of the situation in development of various farm products in order to maintain balanced development and standards for agricultural production.

Let us pose a problem here: How is the problem of readjustment of internal price parity for agricultural products to be handled? Nowadays the peasants psychology is fear of change of government policies. I suggest that the authorities concerned might consider use of the method of announcing once each year procurement prices to be paid for agricultural products, i.e., during August or September of each year to announce the procurement prices to be paid during the following year for various agricultural products, making this into a system whereby the state institutes plan guidance for agriculture so as to assure that peasants will have relatively full time in which to think about and make arrangements for the following year's agricultural production. A once annual announcement of procurement prices for agricultural products does not mean a general annual readjustment of procurement prices for all agricultural products, but rather only necessary readjustment of situations where procurement prices for a small number of agricultural products have been overly high or overly low. The extent of annual readjustment should not be overly great either; readjustments should be divided up over a period of several years so as to avoid creating great fluctuations in production of these agricultural products and so as not to create hardships for the peasants in readjusting planting plans. Each readjustment of agricultural product procurement prices should give full concurrent concern to the interests of the state and the peasants, should be done in coordination with overall departments, commercial departments, and agricultural departments.

Second is promotion of the institution of a contract system for procurement of agricultural products. Yet another major reason why China's economic crop growing area has increased abruptly during the past 2 years has been lack of any restraint by legal regulations. The state stipulated only procurement prices for agricultural products; it did not a priori stipulate procurement quantities or certain agricultural products the supply of which might be greater than demand, but rather used economic agreements between peasants and commercial departments to provide for concrete implementation. Consequently, in a situation in which supply was greater than demand for certain agricultural products (such as rapeseeds and flue-cured tobacco), the peasants continued to offer for sale large quantities of these agricultural products. Under these circumstances, commercial departments could only select two roads. One was to suspend or limit procurement causing attendant losses in peasant earnings and a waste of social wealth, plus a loss of peasant confidence and a dampening of peasant enthusiasm for production, or, second, unrestricted procurement resulting in difficulties in processing, storage, and marketing, or increasing burdens on state coffers, plus stimulating blind development of production during the following year of these very same agricultural products. In order to change this state of affairs, while setting equitable internal price parities for agricultural products, it was necessary to promote institution of contract systems for procurement of agricultural products. General institution of contract systems for procurement of agricultural products must become the fundamental way in which the country undertakes future procurement of agricultural products. Agricultural production procurement agreements cannot simply stipulate the kinds and quantities of farm products peasants are to sell to the state; they must also stipulate the substance of what commercial departments are to provide the peasants in the way of means of production and certain materials urgently needed in their daily lives.

We believe that the defining of equitable internal price parities for agricultural products and promotion of the institution of contract systems for procurement of agricultural products are mutually complementary aspects for the realization of planned guidance in development of agriculture, which both employ predominantly economic methods and contain a certain amount of administrative interference, which both helps bring into play peasant initiative and is able to assure state planning. So long as work in these two realms is done well, China's agricultural production will not leave the track of a socialist planned economy.

Wu Shuo [0702 4311] (Supply and Marketing Bureau, Ministry of Commerce):

1. The Present Status, Trends, and Objectives of China's grain problem

The grain problem comprises the problem of food to eat, the problem of the use of grain as a raw material for industry, and the problem of the use of grain as livestock feed.

The problem of food to eat has been substantially solved. In 1980, per capita grain rations averaged 493 jin for the country as a whole, including 504 jin for the agricultural population, and 438 jin for the non-agricultural population. These quantities are sufficient for consumption. In the cities and towns, virtually every family had surplus grain. In rural villages distribution of grain rations was uneven with some peasants not consuming all they got while a small number of peasants were a little short.

In the use of grain as a raw material for industry, needs are being substantially met. In 1980, industry used about 30 billion jin of grain, of which 25 billion jin was used by the food industry (the state supplying more than 22 billion jin).

The problem of grain for use as livestock feed is far from solution. In 1980, verifiable use of grain for livestock feed was between 60 and 70 billion jin. This plus grain produced by private plots and surplus grain rations used for livestock feed produces an estimate of somewhat more than 100 billion jin. In 1980 average per capita output of meat (pork, beef, lamb and goat), eggs, and poultry was only somewhat more than 30 jin and milk was less than 3 jin, supplies unable to meet demand. Extrapolation from representative data showed annual peasant consumption of meat, poultry, and eggs to have been only 19 jin, and consumption by residents of cities and towns was also no more than 48 jin per capita.

The future trend for the non-agricultural population's consumption of grain is toward decline. This trend began to appear in 1978, and 1980 showed an 8.4 percent drop from 1977. Grain ration consumption levels for peasants in places in which peasants were already eating well also showed a trend toward stability or gradual reduction. In places with low grain rations, the trend has been toward increase. In short, the trends are for no future continued large increases in grains used as staples, but rather, over the short run, consumption will either remain stable or increase only slightly. With the rise in economic income and increase in non-staple foods, the trend will be toward steady decline. The trend is toward increase in requirements for food in which grains are the major raw materials, particularly in rural villages. Because of limitations on the level of purchasing power, over the short term in cities basically about half of employee households having above medium incomes will be able to increase the quantity of food they consume. The trend for use of grain in livestock feeds is toward year after year increase. It can be predicted that the livestock feed industry will become a rising industry.

Just how much grain will have to be produced in order to be able to assure society's grain needs? Two criteria may be hypothesized to make calculations as follows: One is the amount of grain required in a planned diet; the second is the quantity of grain required during a set period of time.

Calculations on the basis of the first criterion show that if the average per capita amount were 736 jin, the objective could be attained. If, in addition, consumption of meat, eggs, poultry, and milk were to increase, there would be a corresponding increase in the amount of grain available for use in livestock feed.

Calculations on the basis of the second criterion: A look at changes in grain requirements for many years shows an annual increase of somewhat more than 10 billion jin in the total amount of grain produced is sufficient only to maintain existing consumption levels. With an annual increase of about 20 billion jin, slight improvement could be made. With an annual increase of about 30 million jin, life would be rather pleasant.

2. Development of production has to be accompanied by working along several lines at the same time for equitable distribution and economizing use.

Equitable distribution of grain, particularly of commodity grain, requires correct handling of the relationship between the state and the peasants as well as the various relationships within the country. For a considerable period of time in the past, the contest over amounts has been very prominent with the state wanting to buy a little more and the peasants wanting to keep a little more. During the past several years the conflict over amounts has basically changed into price conflicts. In a situation in which a "scissors" still exists between prices for industrial and agricultural products with the price parity for agricultural goods being inequitable, the peasants want to make a little more money from their sales of grain, and thus the price conflict is pronounced.

Right now the most important problem in equitable distribution of commodity grain is good handling of the economic relationships among all parties within the country. Following institution of a system of assumption of sole responsibility in public finance, if the economic interests of all parties are not well coordinated, equitable distribution of commodity grain will be affected. Major ways in which distribution of commodity grain can be inequitable are as follows: (1) Output of a certain grain increases and state procurement increases; consumers demand improvement in the consumption situation, but increased grain consumption will require increases in marketing price subsidies. In a situation in which the more marketed the more the loss and the less marketed the less the loss, the marketing areas have no enthusiasm for increasing the amount of supply, artificially creating a relative surplus production of a certain kind of grain for a certain time in a certain place. (2) Quantity of rural grain sold amounts to 53 or 54 billion jin or 45 percent of state procurement and excess procurement figures, exceeding the real quantity of grain deficit, a false amount of demand occurring estimated at between several billion to more than 10 billion jin. (3) Areas into which grain has to be transported want more brought in, and areas from which grain is sent want to send out less, the shortfull becoming the problem of the central government. (4) Some places not suited to the growing of grain but suited to the growing of economic crops have no choice, if they are to receive a grain ration, but to restrict development of economic crops. On the other hand, some places suited to the growing of grain have no choice but to restrict peasant growing of low yield economic crops so they can supply raw materials for local light and textile industries. (5) In some grain producing areas, particularly newly developed areas in which grain production is concentrated, repeatedly experience "difficulties in harvesting grain," and "difficulties in selling grain."

Reasons producing these phenomena are principally no organization of commodity flow by economic areas, which causes a certain segmentation and blocking of flow channels in centralized socialist markets. The inversion of procurement and sale prices of grain deepens this state of affairs. The way to solve it is: (1) gradually solve the price inversion problem. (2) organization of commodity grain flow on the basis of economic regions, beginning first with grain purchased at negotiated prices.

Economizing grain entails mostly the most economic and most scientific use of grain. (1) The utilization value, particularly the nutrient content of various grains, has to be used to the full to attain best economic results and so that everything is used to the full. (2) Where conditions permit, a gradual change should be made in the habit of eating rice, beans replacing come of the rice.

(3) Gradual change in the use of pork as the principal meat diet using the hog feed thus saved to raise chickens for a great increase in the amount of meat from the same quantity of feed. (4) Development of the livestock feed industry and encouraging scientific feeding methods for earliest possible development of the livestock feeding industry.

Wang Fenglin [3769 7685 2651] (Agriculture Economic Institute, Chinese Academy of Social Sciences): Nowadays everybody unanimously agrees that agriculture too must practice a program of taking the planned economy as the key link with market regulation being supplementary. However, divergent views exist as to whether or not the state should hand down to the people's commune collective economy plans of a command nature. Some comrades believe the state cannot hand down plans in the nature of commands to rural communes and brigades, the reasons being that rural communes and brigades are the collective economy with independent accounting and responsibility for their own profits and losses, which differs from the economy owned by all the people; in the classic of Marx, Engels, Lenin, and Stalin there is no discussion of handing down plans in the nature of commands to the collective economy; China's recently published constitution (draft) talks only about the collective economy accepting state plan guidance. Still other comrades suppose that the country can and should hand down to rural communes and brigades some plans in the nature of commands, the reasons being that China's rural communes and brigades are a form of a socialist publicly owned economy possessing only relative independence; and are not an entirely independent enterprise. Since the state assumes definite responsibilities for them, the state has the right to hand down some plans that are in the nature of commands; a basic indicator of a so-called planned economy is plans in the nature of commands; an economy without definite plans in the nature of commands cannot be said to be a planned economy. These comrades also reason that certain major agricultural products are currently insufficient, so in order to satisfy the needs of urban and rural people and assure the planned proportional development of the national economy, some plans in the nature of commands have to be handed down.

I believe that in theory the state should not hand down plans in the nature of commands to rural communes and brigades; however, in proceeding from current Chinese realities, in order to assure the needs of all quarters for major agricultural and sideline products, the state may hand down some plans in the nature of directives, and rural communes and brigades must assure their fulfillment. However, such plan norms should be used as little as possible, and as productivity develops with agricultural products becoming increasingly abundant, this kind of plan should be gradually abolished. This is exactly like the "price scissors" that currently exists between industrial and agricultural products, which though not entirely equitable is something that we cannot abolish nevertheless, but rather can gradually reduce and finally eliminate as productivity develops.

As to how to guarantee fulfillment of this portion of plan norms in the nature of commands, I believe attention must be given three points: (1) A good job of investigation and study to formulate scientific and farsighted plans making them accord with the objective economic laws of planned proportional development, correctly handling the interests of the country, the collective, and individuals. Herein lies the authoritativeness of plans. (2) Adept application of economic levers (in which prices must be particularly equitable) and necessary administrative measures. (3) When conflicts exist between state plan norms in the nature of commands and plans reported to higher authority by communes and brigades, repeated discussions should take place, the views of whoever is right being carried out, and not simply doing things. If in the end conflict still exists, indoctrination should be given to convince communes and brigades of the importance of the overall situation, that the national interest is also the peasants' longterm interests, and that state plans must be resolutely followed. Otherwise, one cannot call these plans in the nature of commands.

Yu Jiabao [0205 1367 1407] and Liu Delun [0491 1795 0243] (Agricultural Economics Department, Beijing Agricultural University. We understand the fundamental meaning of the so-called rural collectively owned economy taking the planned economy as the key link with market regulation being supplementary to be the following: Under conditions of public ownership, the socialist economy has as its objective the use of production to satisfy the needs of the people, and a planned economy in which exchange is conducted in the form of commodities. This formulation reflects the need for all sectors involved in socialist production to carry out planned development to meet the needs of the people, with there being no blind production and a state of anarchy being allowed to exist. However, during the stage of socialism, it is impossible to make every bit of production part of state plan. For production outside of plan, it is necessary to permit enterprises to organize production on the basis of market changes. In collectively owned agriculture, practice of a program of taking the planned economy as the key link with market regulation being supplementary is an objective requirement for the development of agricultural production, and it is also wherein the fundamental collective economic interest lies. This is because of the following:

1. The collectively owned economy is a form of the socialist publicly owned economy. The existence and development of any collective economy has as its prerequisite the existence and development of the publicly owned economy of the entire society. Increase in a collective economy's levels of production and levels of income depends on a rise in the production levels and income levels of the entire society. The fundamental interests of collectively own economic organizations is one and the same as the interests of the entire society.

2. People's needs are limited by the level of development of productivity. Under certain socio-economic conditions, there is a consumption structure and a demand structure. The production structure determines people's demand structure, and the production structure also changes as the demand structure changes. If the production structure does not correspond to the demand structure, either a shortage or an overstocking of products will occur, and this is a reflection of the contradiction between the demand structure and the production structure. In real life, a lack of congruence between the production structure and the demand structure is unavoidable. There are only

two ways in which to resolve this contraction. One is through the laws of value, spontaneously inducing changes in the production structure in the direction of the demand structure. This will cause price fluctuations. The second way is to carry out planned regulation on the basis of requirements of the demand structure and forecasts of people's demands on the demand structure so as to avoid blind development of production that causes waste.

3. The goal of collective economy production value also requires that utilization value of production by the collective economy be consistent with society's requirements; otherwise if the utilization value of production is not needed by society, its value cannot be realized. But how can a small collective unit know the needs of the people? One way is to obtain information from markets. Another way is to understand the needs of the people from state plans. However, state plans cannot thoroughly understand the advantages each enterprise enjoys or know the specific needs for every individual agricultural product. Therefore, allowing enterprises to take the initiative in satisfying people's needs for products on the bases of information about market changes is entirely necessary.

Bi Baode [3968 1405 1795] (Agricultural Economic Department, Chinese People's University). My incompletely formed views on solving the loss of control situation that now exists in agricultural production are as follows.

This February and March we made a survey in Sichuan and Hubei provinces. We had a sense that agricultural production has really developed fairly fast during the past several years. However, at the same time a certain loss of control has also really taken place from agricultural production to the flow of agricultural products.

A look at Sichuan Province shows rapeseed production to have developed very rapidly in recent years. The growing area cannot be controlled and quantities procured by the state have increased drastically and cannot be consumed within the province. Moved outside the province, no one wants them either, so there is large overstocking in warehouses. In 1978 Sichuan Province grew 88,000 mu of rapeseed and by 1981 this had increased to 200,000 mu, a 127 percent increase. Meanwhile, year after year cotton production did not fulfill plan.

A look at Hubei Province shows that it is mostly the tobacco and hemp growing areas that cannot be controlled, and that the area planted to grain has declined. In 1979 Hubei Province planted 312,000 mu of flue-cured tobacco. By 1981, the area had increased to 439,000 mu, a 40.6 percent increase. In 1978, the area planted to various kinds of hemp in the province was 300,000 mu. By 1981, this had been expanded to 360,000 mu, a 20 percent increase. Meanwhile, the area sown to grain in the province dropped from 83 million mu in 1978 to 77 million mu, a 7.2 percent decline.

Procurement prices for agricultural prices cannot be controlled either. As a result of the lower and lower base procurement figures during the past several years, and the higher and higher ratio of procurement at increased prices and negotiated prices, plus various subsidies, returns of profits, and award sales on top of prices, the actual average procurement price paid for farm products is much higher than the state list price (plan price). Calculations done in Jianyang County in Sichuan Province show that in 1981 for the county as a whole the actual average procurement price paid for grain was 19 percent higher than the state list price, and 47 percent higher in the case of rapeseed.

In short, for those products the production of which should increase, no increase occurs while for those products production of which should decrease, no decrease takes place. Products that should be procured cannot be procured, while no further procurement is possible of goods that sell slowly or that are already overstocked. Average prices paid for procurement are actually far higher than planned prices, and the burden on the national treasury becomes increasingly heavy.

How should these losses of control be regarded? I believe that the loss of control in the agricultural production and flow area has resulted from the failure of agricultural plan guidance and management work to keep apace of the changed situation, and from the inappropriateness of certain measures.

In future, just how can a program of taking the planned economy as the key link and market regulation as supplementary be maintained in agriculture? Our initial thoughts are as follows:

First is continued restructuring of the agricultural planning system for a gradual transition to planning of quantities of commodities. Practice in agricultural planning work during more than 30 years in China has shown that it is planning of quantities of agricultural commodities that plays a genuine guiding role. This is because at the present time about 70 percent of all the country's farm products are for self-sufficiency. There is neither any need nor any possibility of making this entire portion of farm products a part of plan with plan guidance being given by the state. In order to assure that the country has the farm products it needs, while handing down plans for quantities of agricultural commodities, we can now also hand down the areas to be sown to grain and major industrial raw material crops and output control norms. However, we should gradually make a transition to full commodity quantity planning.

Second, the emphasis of future agricultural planning work should be on long-range planning. We should devote great efforts to doing a good job of agricultural zoning to solve longrange strategic problems in the development of agriculture, to readjust the structure of agricultural production and crop patterns, to do a good job of building agricultural commodity bases, etc. Annual plans should emphasize policies and actions.

Third, the laws of value have to be honored and full use made of the regulatory role of economic levers. The task at the moment is to make fairly equitable the internal price parities for farm products so that roughly equivalent benefits are derived from the growing of various kinds of crops.

Fourth is the need to promote widely the economic agreements system.

Fifth is institution of needed administrative and legal measures to assure realization of state plans.

Lu Wen [4151 2429] (Chinese Rural Development Research Center)

1. Planned economy and market regulation are the unity of contradictions.

One of the fundamental characteristics of a socialist economy is the planned economy. Agriculture is the foundation of the national economy, and it is closely related to industry; therefore, it is necessary to practice a planned economy. However, since the country's level of development of rural productivity is not high, and because our plans are not sufficiently complete, it is necessary to use market regulation to assist and complement it. Many people have testified to this. However, as to what is meant by a planned economy, what is meant by market regulation, and the relationship between the two has different explanations.

My understanding is that planned economy means consciously and in accordance with social production's objective necessary proportions to run an economic system of production and flow. This is an embodiment of the laws of planned proportional development in social production and flow. It forms a unity with the laws of value. In terms of the original meaning of the laws of value, it has some unity with planned economy. State plans have to be able to reflect the needs of planned proportional development of all sectors of the national economy; they have to try to readjust the proportion of all kinds of production, and they have to establish an equitable production structure, meaning that they must take into consideration the labor, expenditures, and benefits in all kinds of production, and meaning that their relationship between value and price has to be watched, with conscious application of the laws of value to formulate plans. Where plan and realities are out of synchronization, one should not revise plan on the basis of realities, but rather one should use the laws of value and the role of market regulation to provide the necessary administrative action to attain plan objectives.

The marketplace is the territory in which one commodity is exchanged for another. Aside from the portion they consume themselves, the various products our rural villages produce are exchanged through the buying and selling of commodities. In the flow of our commodities, it is also the planned economy that is dominant. In a certain sense, in accordance with the laws of planned development, the state consciously applied the laws of value and exercises regulation through markets. If there is planned readjustment of prices, added price paid for excess procurement, negotiated price procurement, award sales, etc., which affect production and flow, this is also a kind of market regulation, but generally these are included within plan regulation. Outside of state plan, the operation of market supply and demand and the laws of value in the regulation of production and flow is only a part of market regulation. When we ordinarily speak of market control, it is this portion that is meant.

From this may be seen that in our present economy, plans and the market, plan regulation and market regulation possess a unity and are mutually intertwined.

Naturally, there are also contradictions between the two, and this contradiction is the anarchic state formed by plan arrangements and the spontaneous functioning of the market. This means that the anarchic state of the market interferes with and assaults the planned economy making it difficult to carry out plans smoothly. A fairly good way in which to solve this contradiction is to formulate equitable plans on the basis of the unity of the two and to use economic methods to carry out readjustments on the basis of economic laws in order to achieve plan objectives. However, in the present economic state of public finances and a situation of lack of thoroughness in planning work, plus no complete reliance on economic methods to solve problems, administrative measures must also be taken at the same time, measures such as centralized procurement, assigned procurement, planned supply, and strengthening of market management, etc.

2. How can a program of taking the planned economy as the key link and market regulation as supplementary be carried out?

The entire national economy has to institute a program of taking the planned economy as the key link market regulation being supplementary. However, because of some characteristics of agriculture and rural villages, comprehensive and thorough planning is inachievable in the agricultural economy, and reliance solely on administrative measures will not work either. It is necessary to have planned aid from economic measures to use the regulatory role of markets plus necessary administrative methods in order to be able to meet plan requirements.

Looked at from a longrange standpoint, in order to institute a program in agriculture and in rural villages of taking planned economy as the key link with market regulation being supplementary, it is necessary to solve the following several basic problems:

First it is necessary to improve our planning work so that, to the maximum extent possible, plans reflect the requirements of objective economic laws.

Second, we must restructure our price system, establishing an equitable price system founded on value so that prices meet plan needs.

Third is satisfactory solution to problems existing in level by level management. Level by level management cannot be converted into ownership by a department or ownership by a place. Portions that should be under centralized state control should be centralized by the state.

Fourth is the need to use systematic scientific thinking and methods to guide agriculture and all kinds of production, giving attention to each and every link before production begins, while production is in progress, and after production is finished, watching various relationships ahead and behind, to the left and to the right.

During the short term, I believe it is necessary to do a good job of the following several tasks: (1) Combine perfection of rural grassroots organizational work, improvement of production responsibility systems, and doing a good job of contract agreements work. (2) A good job of readjusting agricultural product base procurement figures and proportions. (3) Proper readjustment of inequitable farm product prices. (4) Intensification of ideological work and administrative management. However, one should not use administrative actions as a principal method.

Chinese Agricultural Economics Society director, Comrade Cai Ziwei [5591 1311 0251] said: It is very necessary for use to explore both theoretically and practically how to carry out a program of "taking the planned economy as the key link with market regulation being supplementary." How to put into effect the taking of the planned economy as the key link following institution of production responsibility systems in agriculture is a very important question. Agricultural production has had sustained development during the past several years, but national subsidies from public funds have become more and more numerous, and how to solve this contradiction requires penetrating study. It is necessary to go into rural villages to investigate and study to find means of solving this problem.

MINISTRY OFFICIAL ANSWERS QUESTIONS ON AUTUMN HARVEST

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 7, 1982, pp 2-3

[Article: "Use of Every Available Means to Win Summer Autumn Harvest. Responsible Person in Ministry of Agriculture, Animal Husbandry and Fishery Replies Correspondent's Questions"]

[Text] What is the agricultural production system for the first half of this year, and what further exertions can be made to win a bumper autumn harvest? This is a question about which people are universally concerned. Recently, a responsible person in the Ministry of Agriculture, Animal Husbandry, and Fishery answered questions posed by the correspondent.

Question: What is the agricultural production situation for the first half of this year and is there need to give special emphasis to the winning of a bumper autumn harvest?

Answer: During the first half of the year, as a result of the efforts of the hundreds of millions of peasants, the damage caused agricultural production by serious natural disasters including low temperatures, drought, and hot dry winds was reduced, and a fairly good summer grain and oil-bearing crop will be harvested. Except for some provinces, municipalities and regions in North China, which sustained a decline in summer grain output, most of South China harvested bumper crops, and it is predicted that total output for the country as a whole will be close to last year's level. Rapeseed output, which has increased for 3 consecutive years, increased by another 4 million dan over last year. Throughout the country spring sowing was completed fairly well. In North China crops harvested in autumn grew well, and in South China paddy rice grew better than in previous years. Growth of economic crops such as cotton was also rather good. Commune and brigade enterprises continued to move forward, and new growth also occurred in forestry, animal husbandry, sideline occupations, and fisheries, output of meat, poultry, milk, and eggs increasing substantially from the same period last year. The entire agricultural production situation continues to develop in a favorable direction.

Now the summer solstice has passed and the crucial time has arrived for growth of autumn crops. The pressing matter of the moment is further mobilization, greater exertions, and the adoption of energetic measures to win a bumper autumn harvest in fulfillment of this year's increased production quotas. It is autumn that is most important for agricultural production in China, both the autumn grain area and output amounting to two-thirds the total for the year. Most economic crops are also harvested in autumn. Not only will the autumn harvest have an extremely great bearing on fulfillment of quotas for the year as a whole, but it will directly affect improvement of the people's livelihood and readjustment of the national economy. During the past more than 10 years the country's grain output has developed rapidly and fairly steadily with average annual incremental increases of 5.7 percent. For fall grain, the average annual incremental increases has been 2.1 percent, the low but steady increase in fall grain output adversely affecting the speed of agricultural development. This year planned gross output requirement amounting to 667 billion jin, a more than 17 billion jin increase over last year. Inasmuch as summer grain production was not all that had been hoped, the autumn grain production quota has been made heavier. In most parts of North China the drought situation continues serious; some autumn crops have been hurt and are not growing well. Consequently a good job of autumn production is extremely important. It has to be realized that many favorable conditions exist for doing a good job of autumn production, and that the potential is very great. In 1970, 1973, and 1979, bumper autumn grain harvests were brought in for an annual increase of 30 to 40 billion jin or more. Therefore, with resolute establishment of confidence and determination in winning a bumper harvest for the year as a whole, attention given crucial measures, and every link in production gripped tightly and completely, it will certainly be possible to win the initiative, assure a bumper autumn harvest, and fulfill increased output quotas.

Question: In order to increase autumn production, what problems in the guiding mentality require solution?

Answer: In order to make autumn production rise, the guiding mentality must fully realize and accurately implement a program of "positively no slackening of grain production while actively developing economic diversification." During the past several years, a readjustment of the structure of agriculture has been carried out. For the country as a whole, today crop patterns tend to be equitable. During the past 3 years the grain growing area has been reduced by about 100 million mu, and the economic crop growing area has been expanded for development of economic diversification. The readjustment of agriculture has been well done and has been successful. In order to insure steady growth in grain, the grain growing area must be stabilized with no further reductions. However, a look at this year's circumstances shows a trend for continued decrease in the grain growing area, which should arouse plenty of serious attention. Grain affects the national economy and people's livelihoods; it bears on issue of 1 billion people having food to eat, and it is also the foundation for all around development of farming, forestry, animal husbandry, sideline occupations, and fisheries. It is necessary at all times to place grain production in an important position and conscientiously arrange grain production in accordance with the principle of taking the planned economy as the key link with market regulation being supplementary. In areas in which summer grain production dropped, in particular, it is all the more necessary to exert great efforts and give prominence to taking a firm grip on autumn grain crops. South China must take a firm grip on late rice crop plowing preparations, do everything possible to grow a little more, and strive to increase yields per unit of area so that late rice output will make new breakthroughs. In addition, it is also necessary to give diligent care to various economic crops to sustain increases.

Question: In order to make autumn production rise, what key measures should be given attention?

Answer: Agricultural production is strongly regional and strongly seasonal. It has to be done by adapting general methods to specific places and specific crops, by devoting attention to several key measures, and by solving, in a pertinent way, problems existing in production. Because of the protracted drought in North China, there are serious gaps between plants in the crops to be harvested in the fall; plants are small and weak; growth is slow; and the spring sowing on more than 10 million mu had to be delayed until summer. Consequently, it is necessary to take firm grip on the two major links of early care and intensive care, to do much hoeing and much weeding and loosening of the soil, fertilizing sensibly, using fertilizer scientifically, making full use of effective high temperatures and fertilizer and water conditions, promoting early development and fast growth, nurturing sturdy seedlings, and reducing damage from low temperatures or early frost following the growing season to win high yields. In addition to taking good care of the early and intermediate rice in South China, strict attention has to be given the double crop late rice. For the country as a whole, the early and late rice growing area is more or less the same, but yields per unit of area from the late rice crop are low, total output being between 20 and 30 billion jin less than for the early crop. The main reasons for the low late rice output are a shortage of fertilizer, late transplanting, or numerous disasters. Experiences have to be diligently summarized for on time early transplanting and fertilization to advance safe full heading and to avoid or reduce damage from the cold dew winds as well as to prevent and control diseases and insect pests, using every available means to increase late rice yields per unit of area.

It is during the autumn crop growing season that various natural disasters occur most frequently; therefore, one must be prepared to combat disasters to win a bumper harvest. There can be positively no hoping for or trusting to the favors of Mother Nature. The drought, high winds, low temperatures, and in some areas the floods, waterlogging, and snowstorms during the first half of this year caused great losses for agricultural production in many places.

Weather forecasts also call for quite a few disasters during the last half of the year. Between May and August, continuous drought may occur in North China with flooding and waterlogging occurring in areas of the Huang He and Chang Jiang. In South China and most of the southwest, precipitation is likely to be heavy, and in the northeast, temperatures may tend to be low, all of which requires good preparatory work to prevent and combat disasters. The farmland capital construction work that has been done for many years has been tested in combat against disasters and has played a tremendous role. However, China's ability to withstand disasters is still not very strong, and many places have not fully gotten away from relying on heaven to provide food to eat. Preparations must be made mentally and through measures to achieve unflagging efforts, to avert peril through preparation, and to reduce disaster damage to the minimum.

A bumper harvest in autumn requires cooperation among agriculture, industry, and commerce. Agriculture departments need to conscientiously change their work styles, enhance investigation and study, promptly understand new circumstances and new problems, exchange information with all sectors, and gain the support of all trades and industries for agriculture. For the funds, materials, and particularly the fuel, electric power, and other materials needed for disaster rescue, all jurisdictions should make prompt arrangements and ready supplies in order to assure needs for development of agricultural production.

Question: The key to winning a bumper autumn harvest in agriculture lies in strengthening leadership. What work should now be taken in hand?

Answer: Party and government leadership are the basic guarantee of winning a bumper autumn harvest. First of all it is necessary accurately to carry into effect the party's programs and policies. Right now most important is continued perfection of production responsibility systems, and accurate handling of the relationship between "centralization and contracting," production teams, centralizing whatever can be best managed centrally and resolutely contracting to commune members whatever can best be contracted by commune members for full arousal of the enthusiasm of the masses to bring into play the superiority of the collective economy. It is necessary, in addition, to reorganize grassroots level leadership teams. Following institution of production responsibility systems, the load on cadres has become heavier rather than lighter, so there positively can be no throwing up one's hands and not caring. Second is the need to arouse mentalities, making full use of all forms of major efforts to shape public opinion to improve the understanding of the broad masses of cadres and people about the major importance of giving attention to autumn production, directing their attention promptly to doing a good job of autumn production and to suggesting ways and means of winning a bumper autumn harvest. Third, leaders of all levels have to further change their work styles, go down to the grass roots, investigate and study, and give particular attention to discovering new circumstances, studying new problems, summarizing new experiences, and helping with solutions to problems existing in production. Only if the foregoing tasks are taken firmly in hand and various measures for increasing output translated into reality can a bumper autumn harvest be assured.

EXPECTED TREND OF DOUBLE CONTRACT RESPONSIBILITY SYSTEMS EXAMINED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 7, 1982 pp 24-26

[Article by Zhang Guangyou [1728 1684 0645]: "Exploration of Trend of Development of "Double Contract" Responsibility System"]

[Text] Since the Third Plenary Session of the 11th Party Central Committee, rural villages everywhere throughout the county have established and perfected various forms of production responsibility systems that have fully aroused the enthusiasm of the broad masses of peasants to generate a flourishing and heartening situation in the country's agricultural production. As a result of several years of repeated experiences, today the "double contract" form (contracting fixed output quotas to households and contracting work tasks to households) has come to be selected as the production responsibility system that holds a leading position in the country's rural villages; it is the major form of all the responsibility systems. According to incomplete statistics, the "double contract" form of responsibility system is used in more than 70 percent of places throughout the country. This includes places like Guizhou, Gansu, Ningxia and Hunan, where it is used 90 percent of the time, and places like Anhui, Nei Monggol, Fujian, and Jiangxi where it is used more than 80 percent of the time. Among the "double contract" responsibility systems, mostly it is the "contracting of work tasks to individual households" that is used most frequently, and today the trend of development is some provinces and regions is toward use of this form of responsibility system. Consequently, what the trend of future development of this sort of responsibility system will be has become an extremely important question of general concern. I would like to discuss some of my own views on this issue.

Need to Make Clear the Nature of "Double Contract"

In making clear "double contract" particularly the future trend of development of the contracting of work tasks to individual households, it is necessary, first of all, to clarify a premise, namely the nature of "double contracts." A look at realities in some places shows that during the past 3 years, discussion of this issue has been extremely heated, and that serious divergences continue to exist right up the present time. For this reason there are clear differences in attitude about handling "double contracts." After the CCP Central Committee forwarded "Minutes of the National Rural Work Conference" this year, the mental perceptions of an overwhelming majority of cadres and the masses became fairly unified. Everyone realized that "double contracting" is not an issue of orientation or line, but that it fits in rather well with realities in most parts of the country and is a form of responsibility system that has been heartily welcomed by the broad masses of peasants. As Comrade Hu Yaobang said during October last year when greeting delegates to the national rural work conference: "Our policies have not shaken the collective economy; land, the most fundamental means of production, is still collectively owned. Contracting in itself causes no change in the nature of the collective ownership system. 'Dividing the fields' is a customary way in which peasants speak, but to say that the contracting of production to households is 'dividing the fields to work them alone' is inaccurate."

A large quantity of facts fully demonstrates that "double contracting" is not 'dividing the fields to work them alone', nor is it individual economy, and much less is it the same thing as the small agricultural economy of the period before Liberation. However, an extremely small number of people even today do not recognize the contracting of work tasks to individual households to be a kind of responsibility system. Or else they acknowledge it in words, but in their thinking they have completely failed to resolve, or they have not completely resolved, the problem. One thing they say is that "'double contracting' causes a separation of land ownership rights and land utilization rights, and that ownership rights do not play a decisive role. Consequently, 'double contracting' is actually working alone." Such a statement obviously does not fit the facts. Among production relationships, it is the ownership of the means of production that plays a decisive role and this is true in any society. In fuedal society, ownership of the land is by landlord, and renting it to peastants to farm means utilization rights by the peasants. Can one say that the ownership rights do not play a decisive role? Though our society differes fundamentally from feudal society, nevertheless, utilization rights are still not ownership rights. Production teams may likewise exercise land ownership rights. They may, if needs require, announce that land is to be taken back or readjusted for production, and user would have no rights in disposal of the land. Not matter whether work tasks are contracted to individual households or whether production is contracted to households, the land still is owned by the collective and it is not privately owned. Some people say; "Public ownership of the land is in no way able to decide the nature of "double contracts." Some capitalist countries also practice state ownership of land, but can one say they are socialist in nature?" Those who hold such views have forgotten a fundamental premise, namely that the nature of our country is that of a dictatorship of the proletariat. They have forgotten that the problems we study are problems of socialist China under leadership of the Communist Party. A large number of the masses believe that some cadres, particularly some leading cadres, do not thoroughly investigate and study and do not actively lead the masses in solving some of the problems encountered in going forward, but rather that they work hard at throwing cold water, or are unwilling to take various actions, and that they oppose or boycott the "double contracts" responsibility system. Some people handle "double contracting" first by opposing it or not permitting its practice, and later by throwing up their hands and having nothing to do with it in an abandonment of leadership. When they see a problem occur, they gloatingly scream and shout, attack one point to the neglect of all others or even seize on this to negate the "double contracts" responsibility system. This has been a great obstacle for many years in the process of promoting agricultural production responsibility systems.

In the implementation of any form of a responsibility system it is impossible to avoid this or that problem, and "double contracting" is no exception. For various reasons, some problems have arisen in carrying out "double contracts" in some places. Such problems included disputes over water or oxen, the division of the land into overly small plots, failure to use machinery fully, improper protection of collective property, or no provisions for the four dependents households [sic] or the households enjoying the five guarantees [childless and inform old persons guarantee food, clothing, medical care, housing, and burial expenses by the people's communes], etc. These problems had to be given serious attention, and they had to be solved. Not to look at problems from this angle would be wrong. However, principal and secondary aspects had to be distinguished too, and seeing that "double contracts" had fully aroused the enthusiasm for production of the broad masses of people was the most important aspect. Moreover, it was also necessary to realize that the aforestated problems were by no means problems of the "double contracts" responsibility system per se, but were work problems. With a strengthening of leadership, the aforestated work problems could be avoided or overcome. For precisely this reason, in the establishment and perfection of agricultural production responsibility systems, a unified ideational understanding and improvement and strengthening of leadership is extremely necessary. We have to realize that the "double contracts" responsibility system has vitality and has been enthusiastically supported by the broad masses of peasants. So long as the broad masses have enthusiasm, there is no hardship or difficulty that cannot be solved.

No Need to Divide Forms of Responsibility Systems Into High Grade and Low Grade

The contract responsibility systems linking calculation of compensation to output that are currently being practiced in rural villages everywhere are of many different forms, and the ways in which they operate are not entirely the same either. In some cases production is contracted to individual households; in other cases work tasks are contracted to individual households; in still other cases output quotas are assigned individual ablebodied laborers; and in yet other cases output quotas are assigned to teams. Sometimes there is specialized contracting, and sometimes several forms are used at the same time or interchanged. This is the normal situation. However, some people have divided responsibility systems into "high grade" and "low grade." They say that the contracting of work tasks to individual households is the "lowest grade," and they advocate "leading" "double contracts" to the contracting of production to individual able-bodies laborers... Thus they take a discriminatory attitude toward the contracting of work tasks.

Are there really distinctions between high grade and low grade in the forms of responsibility systems? I believe that there is no distinction between high grade and low grade in responsibility systems per se. To divide responsibility systems into high grade and low grade not only does not fit in with objective facts, but such a division may easily produce bad results or side effects in actual work. If one were to make distinctions of "high grade" and "low grade" in responsibility systems, that would depend on whether a certain form of responsibility system suited a given area or not. Only it if suited the area, was able to advance development of production, and was supported by an overwhelming majority of people could this form of responsibility system be said to be a high grade one in this particular area. Conversely, no matter the number of people who believed another form of responsibility system to be "high grade," it if did not fit this particular area, did not help development of production, and was disapproved by most people, then that form of responsibility system would also be low grade. As some people in rural He'nan said: "Whether the form is good or not, one's belly keeps a record; and whether the form is high or low, increases in yields bear testimony." Whether they are good or bade depends on whether or not the masses support them and whether they can fully stir the enthusiasm of the masses. No matter how "wonderful" the form, without the enthusiasm of the masses, all is empty talk.

But just how can one determine which form of responsibility system to adopt. In a nutshell, there are two ways. One is to proceed from realities, and to adapt general methods to local situations. Whatever form suits is the one that should be adopted. Second is to genuinely turn over to the peasant masses the power to make a choice, respect their self-determination, and let the masses decide without the leaders making any rigid regulations, running things themselves without consulting others or, much less, giving blind guidance. In the course of our survey, we explored the forms of responsibility systems selected and the trend of development of responsibility systems, and we deeply feel as a result that the suitability of various forms of responsibility systems depends on objective laws that cannot be changed by people's wills. The process of establishing and perfecting responsibility systems is a process of constantly overcoming and eliminating the effects of leftist ideology, and it is also a process of eliminating metaphysical methods of thinking to carry out out an ideological line of seeking truth in facts. For all forms of production responsibility systems there is a process of accepting testing through practice, and comparative examination and selection by the broad masses. Leaders at all levels have to be careful to avoid being subjective and one-sided in seeking any given form; they should genuinely turn over the power of decision to the masses. Ours is a vast country in which differences in natural conditions and the economic basis are very great, so insistence on uniformity does not fit in with realities. It is divorced from reality and divorced from the masses, and the blind pusuit of so-called "high grade" forms must inevitably produce undesirable consequences.

Some comrades regard the contracting of work tasks to individual households as the lowest form of responsibility system. Second lowest is the contracting of production to individual households; next is specialized contracting and assigning output quotas to individual able-bodied laborers; next is contracting production to teams....Such rankings reflect the erroneous views of some comrades toward "double contracts" responsibility systems. Such views must lead inevitably to the following conclusion: "Double contracting" is an "expedient measure;" and later on the contracting will be done with work teams, production units....Guided by this thinking, some places emphasize "specialized contracting and assigning output quotas to individual able-bodied laborers" with no regard for conditions. I suppose some places can practice "specialized contracting and assigning output quotas to individual able-bodied laborers" because conditions are ready for it, because there are specialities that can be divided, and because the masses want it. However, in some places where there is virtually only agricultural production or, say, only farming with little economic diversification, and where there is as yet not that much specialization, how can specialized contracting be done? Needed specialized division of labor can increase the labor productivity rate in production, but one must proceed from realities; one cannot make a specialized division of labor for the sake of seeking a "high grade" form.

Several years experience has shown that in most places in the country that have developed responsibility systems the fact is that the peasants have like the contracting of work tasks to individual households as a responsibility system. The main reason has been that as compared with other forms of responsibility system, "benefits are most direct, responsibilities are most concrete, and methods are simplest." In terms of natural and economic conditions prevailing in most parts of China, thos form of responsibility system is most suitable. This is another way of saying that it fits in with realities and prevailing levels of administration and management in those areas. In particular, practice of this form of responsibility system entails no evaluation of work and recording of workpoints, and it has been the form most welcomed by the broad masses of peasants. In acertain sense, the contracting of work tasks to individual households is a major administrative and management measure that has been worked out in China's agricultural production in the course of taking the collective path. It has been worked and reworked and a great price has been paid for it. It both takes advantage of the superiority of the collective economy and fully arouses the enthusiasm of the broad masses of peasants. It has solved a fundamental problem that has gone without solution for a long time in the administration and management of agricultural collectivization.

Trend of Development of Contracting Work Tasks to Individual Households

What is the future trend of development of the contracting of work tasks to individual households? Is it true that it will take the same old road of going from households to able-bodied laborers, from able-bodied laborers to work teams, and from work teams to production teams, gradually rising from level to level. I do not believe this is possible, and it will not work.

Well then, just what is the trend of development in the contracting of work tasks to individual households? Following the contracting of work tasks to individual households, mass enthusiasm has been fully aroused, potential for increased production has been tapped, and the labor productivity rate has greatly increased. On the one hand, expansion of reproduction capacity in agriculture itself has increased; on the other hand, some workforces have been gradually separated from agricultural production and transferred elsewhere to open production avenues and to develop economic diversification and commodity production. Working on the principle of voluntary participation for mutual benefit, some of this portion of the workforce has organized new economic collectives; some may be shifted to commune and brigade enterprises to engage in economic diversification and commodity production; and some may go into cultural, scientific, or sanitation work, or else transfer into the service trades. As production develops and the degree of specialization and socialization of production steadily increases, a large part of this portion of the workforce may gradually be removed from agricultural production and take the road of specialized association.

As regards agricultural production, by which is largely meant the farming industry per se, for a majority or an overwhelming majority of households that do farming in a decentralized way there will be no change for a fairly long historical period. A small portion or an extremely small portion may general loose associations or mutual help on the basis of genuince voluntary participation for mutual benefit. The reason is that farming by individual households fits in with the characteristics of agricultural production, and it fits in with the demands of the peasants. The size of production organizations and the number of workers or the number of workers who work together have nothing whatever to do with whether production relationships are progressive or backward, and they do not tell whether labor efficiency is high or low. In China, in particular, where the size of the population is large relative to available cultivated land, peasant production has to take the road of a high degree of intensive farming and succeed through painstaking and meticulous cultivation of the soil. Decentralized farming by individual households also holds possibilities for agricultural mechanization. Modernized socialist agriculture in China proceeding from the country's realities and progressing through exploration can follow its own path.

PRICING OF AGRICULTURAL, SIDELINE PRODUCTS EXPLORED

Meaning of Price Policies

Guangzhou GUANGZHOU RIBAO in Chinese 29 Jul 82 p 4

[Article by Zhang Changcai [1728 7022 2088]]

[Text] In order to control agricultural and sideline products in a planned way and to make overall arrangements with the needs of all concerned in mind, the state has established categories I, II, and III on the basis of the importance to the national economy and the people's livelihood of various agricultural and sideline products. It has also formulated centralized procurement, assigned procurement, and negotiated procurement policies. Practice has shown this policy to be consistent with the country's circumstances and to play a major role in advancing development of agricultural production, in guaranteeing the needs of society, and in fundamentally stabilizing market prices.

Some comrades suppose that all that is necessary for the formulation of procurement price policies for agricultural and sideline products is to follow the laws of value. We believe, however, that centralized procurement, assigned procurement, and negotiated procurement policies must be decided by the nature of the socialist planned economy, and will have to be followed and carried out for a fairly long time to come. This is because practice of this policy fully reflects the principle of taking the planned economy as the key link with market regulation being supplementary. This is to say that for category I and category II centralized procurement and assigned procurement products that are related to the national economy and the people's livelihood and affect the overall situation, in the macro-economy the state has to strengthen centralized unified planned management and necessary administrative interference. For category III negotiated procurement products, in the micro-economy enterprises and individuals enliven the economy. For example, of all the agricultural and sideline products procured by all supply and marketing departments in the country last year, category I and category II production accounted for 83.9 percent, and category III products accounted for 16.1 percent of the total agricultural and sideline products that state commercial departments procured; the portion purchased at negotiated prices came to only 13.8 percent. From this may be seen that centralized procurement and assigned procurement products controlled by and under the mastery of state plan constitute the largest portion. This reflects the dominant role of plan with only a small amount being regulated by the market, which plays a role supplementary to plan.

It should be noted that in implementing centralized procurement, assigned procurement, and negotiated procurement policies for agricultural and sideline products, it is not that there is no desire to use the laws of value, but rather that only by taking the planned economy as the key link is it possible to use accurately and bring into play the role of the laws of value. China must still energetically develop commodity production and commodity exchange. Because of the energetically develop commodity production and commodity exchange, the value of commodities continues to be the basis for price. That commodity price has to be generally in accord with value is an objective requirement of the laws of value. Consequently, in carrying out the planned economy, it is necessary to adopt forms of commodity value, and in formulating plan, the state also has to fully use the laws of value. Practice has shown that whenever procurement prices for commodities have been set equitably and are fundamentally in accord with requirements of the laws of value, peasants can obtain fair remuneration of these agricultural and sideline products that they sell; development of these agricultural and sideline products will be rapid, and state procurement plans will be smoothly fulfilled. Whenever procurement prices are set too low in violation of requirements of the laws of value, peasants are unable to get fair remuneration, development of production is impaired, state procurement plans cannot be fulfilled, and a shortage of supply in relation to demand develops in markets. Whenever procurement prices are set too high, blind development of goods may be spurred; state procurement plans cannot be controlled or large overstocking and spoilage of goods may occur occasioning losses in production. In short, agricultural and sideline product procurement must adhere to taking the planned economy as the key link, but the role of the laws of value cannot be ignored either.

Some comrades have asked whether the higher procurement prices paid for agricultural and sideline products the better, or whether there should be a limit. We believe that there surely has to be a limit. Furthermore, at the present time, a relative stability must be maintained within prevailing limits. This is because of the following:

First, prevailing agricultural and sideline product procurement prices are fairly equitable, and they have increased peasant earnings. As a result of almost 3 years of increased prices for agricultural and sideline products, comparison of 1981 with 1978 shows an average annual incremental increase of more than 10 percent in the procurement prices paid for agricultural and sideline products in the country, but that in the 28 year period from 1950 until 1978, the average annual incremental increase for agricultural and sideline products was only 2.8 percent. As a result of increased prices paid for agricultural and sideline products, the average annual per peasant increase in earnings for 1979 and 1980 taken together was somewhat more than 20 yuan. In Guangdong Province, as a result of increases in procurement list prices paid for agricultural and sideline products during the past almost 3 years, peasant earnings have increased by more than 1.4 billion yuan. The difference between list and negotiated price in money received for agricultural and sideline products peasants sold at negotiated prices was more than 2 billion yuan. It may be seen that following almost 3 years of readjustment, the procurement prices paid for agricultural and sideline products are fairly equitable. This has promoted development of agricultural production, and peasants have also increased their earnings.

Second, great changes have taken place in comparative prices paid for industrial and agricultural products. The comparative price coefficient in the exchange of agricultural and sideline products for industrial products in the country increased by 263 percent in 1981 as compared with 1950, i.e., an equal amount of agricultural products could be exchanged in 1981 for more than one and a half times the industrial goods obtainable in 1950. In addition, yet another major change occurred in the comparative prices of agricultural and industrial products, namely that during the past almost 3 years, as a result of the institution of production responsibility systems in agriculture and the launching of economic diversification, the labor productivity rate has increased and production costs for agricultural and sideline products have decreased. Meanwhile the labor productivity rate in industry has decreased, and production costs have risen in a situation that is just the reverse in agriculture. During the first 11 months of last year, the labor productivity rate for all personnel in industrial enterprises owned by all the people fell 3.2 percent as compared with the same period the year before, and comparable production costs increased 1.1 percent. Because of these changes, the prices for agricultural and sideline products increased relatively and prices for industrial products decreased relatively.

Third, increased prices for agricultural and sideline products also depend on the extent of development of industrial productivity. Increases in agricultural and sideline product prices requires the state to allocate money, and the state's money is provided mostly by industry. More than 90 percent of national revenues come from industry. Consequently, increase in prices for agricultural and sideline products must proceed from the reality of the country's level of development of industrial productivity. On the one hand it is necessary to see whether industry is able to provide corresponding industrial products to satisfy peasant needs. If procurement prices paid for agricultural and sideline products are increased and it is not possible correspondingly to increase the supply of industrial goods, the peasants will still gain no benefit. In addition it is necessary to see the extent to which industrial polants improve economic benefits. This is because in order to increase prices paid for agricultural and sideline products costs for industrial goods produced by plants requiring agricultural and sideline products as raw materials for their manufacture will also increase. Only when industrial plants are able through increase in economic benefits to offset the increased costs occasioned by increased prices paid for agricultural and sideline products can the peasants derive genuine benefits from increases in prices paid for their agricultural and sideline products. Today state price subsidies paid in prices for agricultural and sideline products amount to 32.1 billion yuan. With the increase in agricultural production and the increase in quantities of agricultural and sideline products procured, subsidies will increase annually by 1 billion and several hundred million yuan. Were the procurement prices paid for agricultural and sideline products to be raised as well, construction funds would be reduced and public deficits increased, thereby impairing national construction.

In summary, for some time in the future it will be impossible to raise the purchase prices paid for agricultural and sideline products. The peasants cannot rely solely on price rises to become prosperous, but rather they must rely on efforts to develop production, lower agricultural production costs, and raise labor productivity on the basis of prevailing price levels for agricultural and sideline products to increase earnings.

Increased State Burden

Beijing CAIZHENG [FINANCE] in Chinese No 8, 5 Aug 82 p 25

[Article by Yun Zhiping [0061 1807 1627]]

[Text] In recent years the state has greatly increased procurement prices paid for agricultural and sideline products. In the 3 year period between 1979 and 1981, they rose by a total of 38 percent (including a 23.5 percent increase in list price) for an annual average increase of 11.4 percent, which was fairly great. As a result of the increase in prices paid for procurement of agricultural and sideline products, the interests of the peasants were fairly well taken care of. This powerfully spurred the enthusiasm for production of the broad masses of peasants and promoted development of agricultural production. These measures were correct without doubt. Right now the main problems are: first, some areas act themselves to increase procurement prices, enlarge the socpe of price increases, increase the extent of price increases, increase price differential subsidies, and lose control over negotiated prices. This has meant an increasingly heavy burden for the public treasury. State subsidies from public funds for agricultural and sideline products, for goods used to support agriculture, and for other products increased from 7.9 billion yuan in 1978 to more than 32 billion yuan in 1981, and equalled 32 percent of the national budget. Unless this trend is brought under control, subsidies may exceed the extreme limit that the national budget is able to bear. Second, results have not been very good from payment of increased prices for excess procurement and from procurement at negotiated prices. Total amount of procurement has not increased much, and procurement at list price has become less and less while procurement at increased prices and negotiated prices has increased more and more, adding to the drain on the public coffers. In 1981 quantity of grain procured increased by 15.5 percent over 1978, but quantity procured at list price fell 29.4 percent. Meanwhile procurement at increased prices and negotiated prices doubled and tripled respectively. List price procurement as a ratio of total procurement fell from 69.3 percent in 1978 to 41.7 percent in 1981 while the ratio of added price procurement rose from 24.3 percent to 41.7 percent and the negotiated price procurement ratio rose from 6.4 percent to 16.7 percent. Teh procurement picture for oil and cotton was similar to that for grain. From 1979 to 1981 funds paid for increased procurement at added price or at negotiated price annually averaged more than 4 billion yuan, adding to the burden on public revenues. In addition, because of differences in state requisition procurement base figures, vicissitudes became increasingly serious and contradictions more conspicuous from one area to another and between one variety and another in added prices paid for excess procurement.

In order to stabilize agricultural and sideline product prices and control public fund subsidies, the following measures should be adopted:

First of all, procurement prices for agricultural and sideline products should be basically stabilized within what they have been in recent years. Except for individual items, there should be no further price increases, added prices, or subsidies. Increases in prices, added prices, subsidies, rebates of profits, and such methods that jurisdictions have put into practice of their own volition should be cancelled. In addition, negotiated prices should be restructured in a gradual contraction of the scope and numbers of things included in negotiated prices with stabilization of negotiated price levels and control of quantities purchased at negotiated prices and sold at parity prices to reduce the state's burden. Prices for agricultural and sideline products should be handled in accordance with state regulations with adherence to taking plan prices as the key link and market regulation as supplementary with no doing as one pleases.

Second, consideration could be given to changing the prevailing added price paid for excess procurement of grain, oil, and cotton to an added price for fixed proportions. This would mean setting separate proportional state requisition procurement and excess procurement, arriving at price on the basis of the fixed proportions and the extent of added price. Advantages in so doing are as follows: the interests of both the country and peasants would be concurrently cared for. The more grain, oil and cotton sold, the greater the peasants' earnings and the greater the benefits for the country. All the vicissitudes of added prices for excess procurement could also be eliminated. Furthermore, while protecting the peasants' just interests, inequitable expenditures for added prices could be reduced for a lightening of the drain of public coffers.

Third is use of a system of assignment of sole responsibility for added price funds for grain, oil, and cotton. Right now all the added price funds for grain, oil, and cotton are borne by the central government treasury, which makes for difficulty in strengthening management, ease in expansion of the added price proportion, and increase in the extent of added prices. In order to stir all jurisdictions' enthusiasm for managing added price funds, nationally set base figures could be used in making assignments of sole responsibility to individual provinces, autonomous regions, and directly subordinate municipalities. In the case of excess quantities procured, the user would pay. If the central government were the user, the central government treasury would be responsible; if local governments were the users, local government would bear the burden.

BENEFITS OF IMPROVED VARIETIES OF CROPS EXPLAINED

Increased Yield Potential

Beijing ZHONGGUO NONGMIN BAO in Chinese 19 Aug 82 p 2

[Article by Bu Shouchen [6752 1343 5256], Seed Station, Ministry of Agriculture, Animal Husbandry and Fishery]

[Text] General Yield Increases of More Than 10 Percent From Newly-Promoted Varieties

New varieties that have been approved for promotion by the state produce yield increases of more than 10 percent. Though not all yield increases are as much as 10 percent, the varieties possess superior properties of other kinds. For example, quality may be good, they may be early ripening, be highly adaptable, or strongly resistant to diseases and insect pests, making them worth promoting.

Seed departments in all jurisdictions regularly recommend new varieties to the peasants in order to satisfy urgent rural needs. For example, the new cotton variety, Esha 28, that has been promoted in Hubei Province has produced 38.46 percent greater average yields than Eguang stock variety cotton in area experiments at 31 sites (or times). Its fiber quality is rather good; it is widely adaptable, and its shortcomings are rather poor purity and lack of resistance to verticillium wilt. This new breakthrough variety has been promoted over wide areas of Hubei Province, and it will certainly mean tremendously increased yields for that province. New varieties of grain crops such as the new He'nan wheat variety, Bainong 3217, and Hebei's Jimai No 7, etc., are also being rapidly promoted. Nevertheless, generally speaking, in many places no successor varieties are in sight, so the old varieties that have been used for many years cannot be changed. New breakthrough varieties, in particular, are too scarce.

Purified and Rejuvenated Seeds Product 5 to 10 Percent Greater Yields Than Mongrelized and Degenerate Varieties

Seed mongrelization and degeneration is a major element impairing increases in crop output, and purification and rejuvenation for regular renewal of seeds used is a major means of solving this problem. Practice has shown the following: purified and rejuvenated seeds may increase yields by 5 to 10 percent as compared with mongrelized, degenerate seeds. A survey conducted for 3 years running by the Fengxian County Seed Company in Shanghai Municipality showed yield increases of 6 to 7 percent for wheat, and paddy rice, 10.4 percent for cotton, and 10.2 percent for rape from purified and rejuvenated seeds as compared with seeds of relatively poor purity. In another case, a survey done this year by the Shandong Wheat Inspection Team at Longquan Production Brigade in Laiwu County showed purified and rejuvenated wheat variety, Taishan No 1, produced 92.9 jin per mu, a 14.7 percent increase as compared with unpurified and unrejuvenated seeds of the same variety. In fact, when purification and rejuvenation of varieties is done properly, the varieties are by no means inferior to and may surpass some varieties being newly promoted.

Following Machine Processing and Selection of Seeds, Yield Increases of 5 to 10 Percent

Machine processing and selection of seeds is a new job in China. Use of seeds that have been machine selected can both save on the number of seeds used and on manpower, and can increase yields. Experiments conducted at Jiangling and Jingshan counties in Hubei Province show that after rice and wheat seeds had been selected, the sprouting rate increased by 3 to 5 percent. After defuzzing in sulfuric acid, the cotton seed sprouting rate increased by 10 to 15 percent. Furthermore, according to comparison experiments conducted for many years in Wujin County, Jiangsu Province, and 17 experiments conducted at seven stock variety farms in Changge and Jiyuan counties in He'nan Province, sprouting rates increased by a general 10 percent for seeds that had been selected versus seeds that had not been selected. Under similar production conditions, this meant a 10 percent increase in grain yields from 10 percent fewer seeds.

Today selected and processed seeds account for only about 5 percent of the total volume of seeds used, so a very great potential exists. Were all the country's seeds used for open field crops to be processed and selected as well as mixed with pesticides to prevent diseases and insect pests, a saving of several billion or even tens of billion jin of seeds would be entirely possible to say nothing of the increase in grain output.

Increased Yields of More Than 100 Jin Per Mu From Hybrid Rice

The history of development since founding of the People's Republic has shown the following: each major breakthrough on a crop variety plus other technical measures for increasing yields can result in tremendous increase in outputs. Hybrid rice is one example, with increases in yields of more than 100 jin per mu or even 200 to more than 300 jin in some places.

Hybrid rice has been promoted for 7 years, yet the growing area amounts to only about 16 percent of the total; a very great potential still exists. Currently the situation for the spread of hybrid rice is very uneven. In Sichuan Province the spread has been fairly rapid. As of last year it was being grown on more than 13 million mu with a 2 billion jin increase in grain resulting from this single case alone.

A positive attitude is necessary for development of hybrid rice. Leaders have to make up their minds, see clearly, and then work with determination. A scientific attitude is necessary too. There has to be experimentation and demonstration first, followed by promotion.

Aside from the four aforestated potentials for increased yields, there is still one other. If a superior variety can definitely be grown in a certain area, when grown in another area it may produce decreased yields. A variety may produce increased yields in area A while it will not necessarily produce increased yields in area B or may even produce reduced yields. Today some of the varieties being grown in a place are by no means the optimum varieties for the place, and some places are still giving no concern to local conditions but are blindly advocating the growing of so-called "high yield crops." As to just which crops will produce high yields, only comparative experiments done locally under identical production conditions will show. There has to be an adaptation of general methods to local situations, and if science is not respected, it will be difficult to avoid blind guidance. If this work is done well, increases in yields are possible.

Questions Answered

Beijing ZHONGGUO NONGMIN BAO in Chinese 19 Aug 82 p 2

[Article: "How Can the Peasants' Urgent Needs for Superior Varieties Be Satisfied"]

[Text] Question: What new situations have arisen in seed work since institution of rural production responsibility systems?

Answer: One is that peasant demand for seed quality has gone up. Second, quantities have increased. Third, the scope of seed supply has expanded; not only are grain crop seeds wanted, but economic crop seeds and vegetable seeds are also in demand. Fourth is demand for improvement in the way of doing business that requires seed companies to use flexible methods of many kinds in providing service. Fourth is a requirement for promotion of both superior varieties and superior methods, concern about economic results, and shouldering of economic responsibilities.

Question: How can the peasants' urgent needs for superior varieties be satisfied?

Answer: Production of superior varieties, particularly hybrid seed production, requires strict technical conditions and separation conditions. Only by establishing special concentrated continuous tract seed production bases is it possible to provide peasants seeds of high purity and good quality at low cost. Seed bases include state-owned superior variety farms, seed company bases under special arrangements, commune superior variety farms, and production brigade seed teams. Sole reliance on state-owned superior variety farms cannot satisfy needs. It is necessary to operate commune and brigade seed production bases as well. Because of faulty understanding and abandonment of leadership of production responsibility systems in some places, some commune superior variety farms and production brigade seed teams have been disbanded. This is wrong. Communes and brigades that have already established seed bases should consolidate and improve them, and those that have not yet established them should do so with all possible speed.

Question: What several forms of seed supply are there today?

Answer: In addition to foreign trade in seeds being centrally handled by the China Seed Company, currently the main forms of supplying seeds are as follows: one is supply by seed companies; a second is centralized seed supply by communes and production brigades; and third is county and commune joint seed supply, and county, commune, and brigade, three-tier joint seed supply. In order to assure seed quality and promote agricultural production, other units and individuals may not take it upon themselves to deal in farm crop seeds. Reports from some places tell of unscrupulous pedlars selling seeds at high prices, some of which have been adulterated to cheat people. It is hoped that production units and commune members will not buy seeds at random from unscrupulous pedlars in the streets.

Question: What are the main seeds that seed companies currently deal in?

Answer: First is seeds that are strongly technical and have high commodity value such as hybrid rice, hybrid corn, and hybrid gaoliang. Second is seeds that easily become mongrelized and degenerate, and seeds that are not sown in large amounts such as cotton, vegetables, millet, and rape. Third is stock seeds that have undergone purification and rejuvenation, and newly bred conventional superior varieties. Fifth is seeds prepared for unusual places. Sixth is suprior seeds to provide disaster relief and prepare against natural disasters.

Question: How can the way of doing business be improved to accommodate the masses?

Answer: On the basis of experiences in various places, it is necessary to adopt the following measures: first is to increase the number of seed supply stations and to set up retail stores for close-by supply, or even to deliver seeds to production teams or households. Second, when the masses buy seeds, any amount should be sold them at any time. They should be sold whatever amount they want to buy, and they should be sold then whenever they want to buy them. They should also be permitted to select them and exchange them. Third, in addition to trading grain for seeds, negotiated sales should be permitted to solve the problem of "difficulties in selling grain in exchange for seeds." Fourth is to take the initiative in providing briefings on the special properties, special characteristics, and special qualities of varieties, particularly providing information on growing techniques. Fifth is establishment of a seed salesman system. Sixth is not permitting supply of seeds that are not up to specifications, much less permitting the inferior to be represented as being good in a resort to deception. If it is discovered that varieties supplied were not what was wanted or that quality did not meet requirements, all economic losses resulting therefrom must be indemnified.

ANHUI BEGINS ANTIFLOOD WORK IN STRICKEN AREAS

OW191215 Beijing XINHUA Domestic Service in Chinese 0012 GMT 18 Sep 82

[Text] Hefei, 18 Sep (XINHUA)--The Anhui Provincial CPC Committee and People's Government have organized nearly 200 cadres from units directly under the provincial authorities into 31 work teams to carry out flood relief work. These teams, led by Yang Weiping and Yuan Zhen, secretaries of the Provincial CPC Committee; Meng Fulin, vice governor; and 41 cadres at the bureau and division levels, left for 8 prefectures, 4 cities and 33 counties on 5 September to inspect flood damage and assist local governments in mobilizing the masses to launch self-help activities, resume production and overcome difficulties caused by floods with a view to winning a bumper agricultural harvest for the whole year.

Anhui Province has had good harvests of summer crops including grain and oil-bearing crops as well as early rice. Autumn crops are growing well in most parts of the province and a bumper harvest is in sight. However, some localities have been hit by serious floods and waterlogging. Since early June, continuous and heavy rainstorms hit areas north of the Huai River, between the Changjiang and Huai Rivers and south of the Changjiang River. A total of over 14.9 million mu of crop fields were damaged and 250,000 houses collapsed. The total grain loss is estimated at 2 billion jin.

To minimize the damage, help flood victims arrange production activities and maintain their livelihood with a view to winning victory in the antiflood struggle, the Anhui Provincial CPC Committee and People's Government organized work teams in good time and sent them to the flood-stricken areas to assist local governments in launching self-help production activities. They emphasized that main efforts should be concentrated on developing production by strengthening management of late autumn crop fields, making good preparation for autumn sowing and successfully planting wheat according to the required quality and quantity. At the same time, further measures should be explored to develop diversified economy.

The provincial leadership urged that in the self-help production campaign, major efforts be concentrated on such heavily affected areas as Xiaoxian County in northern Anhui and on the flood drainage and retention areas along the Huai River to enable people there to live a stable life and do production work without worry. Good-harvest areas should assist disaster areas and mutual help should be initiated among the masses in order to unite their efforts in jointly overcoming difficulties.

At present, inspired by the spirit of the 12th CPC National Congress and led by party organizations and people's governments at all levels, the people in Anhui's disaster areas are working with one mind and with full confidence to wage the struggle to overcome the difficulties caused by natural disasters.

GRASSROOTS SUPPORT FOR GOVERNMENT, COMMUNE SEPARATION REPORTED

Beijing NONGCUN GONGZUO TONGXUN [RURAL WORK NEWSLETTER] in Chinese No 7, 1982 pp 17-18

[Article: "Need For Separation of Government and Communes and Need For Gradualism"]

[Text] Following announcement of the revision of the constitution, the He County CCP Committee and people's government in Anhui Province assembled cadres for study and discussion. Remarks they made in discussion of the issue of separation of government and communes have been selected for publication here.

County Civil Government Bureau Chairman Yang Yucai [2799 3768 2088]: I formerly did rural grassroots work for many years. In 1956 I began as a township leader, later on becoming a commune secretary for the last 10 years. I have had a full taste of the joys and trials of commune work. When the new draft constitution seeks to separate government and communes,I raise both hands in support.

If you compare the separation of government and communes during the period immediately following Liberation with the subsequent combining of government and communes, I feel that the separation of government and communes is the better of the two. During the early 1950's a township had only three officials, a political instructor, a township leader, and an office worker. At that time the political instructor looked after party work and understood programs and policies; the township leader looked after administrative matters; and the office worker worked with the township leader to handle grain taxes, to settle civil disputes, and to perform marriages. The deputy director of the cooperative devoted himself to production. Everybody's duties were clear, the division of labor straightforward, and work was done in an orderly way. After government and communes were combined, the commune CCP Committee secretary took on everything. He both headed the party and headed administration and production. As a result, the party replaced the government and the government replaced communes. There was a lot of hustle and bustle yet work was not done well. In 1975, when I was secretary in Luobai Commune, I realized that though the soil was very fertile in the 18 production brigades of this commune, nevertheless they had grain sold back to them by the state year in and year out. I was very agitated and right after the new year I quietly made up my mind that if I were to stay in this production brigade for a year, I would change the low production situation. I told other CCP committee members about my idea, and they supported me. But I remained there for only 2 months that year and spent the other 10 months in meetings, in resolving disputes, in writing comments on reports, wasting my times on such trifles. In all matters great and small, the secretary had to be sought out to give the nod. Even the release of emergency rescue funds and the distribution of chemical fertilizer required my approval before they could be done.

Granted that the blind direction given to agricultural production some years ago was caused by the ultraleftist line; still, the lack of separation between government and the communes cannot be said not to have been a cause. The masses of commune members at Luobai Commune had been in the habit of growing one crop of intermediate rice. This had been dictated by this commune's objective water, fertilizer, and work force conditions. In 1976 the county wanted the commune to grow 15,000 mu of two crops of rice, but neither the production leader nor the masses agreed. During discussions by the commune management committee, five out of seven committee members opposed. The commune management committee deputy chairman, who was of peasant origins and had been born and brought up on the soil, likewise advocated either not growing two crops of rice or growing less of it. At that time I was the commune secretary and concurrently chairman of the management committee. In order to resolutely carry out the instructions of higher authority and without concern for the views of the majority, I finally gave the verdict to plant the 15,000 mu. Because this matter had been handled against the wishes of the people, it was resisted by the production team leader and the masses. For this reason I held eight consecutive meetings of the brigade and production team leaders and repeatedly mobilized and forced subordinates to regard the matter as a political task for fulfillment. As a result, because water, fertilizer, and workforces were not equal to the task, the farming season passed with 3,000 mu not being planted, and 6,000 mu were transplanted without any manure at all. Yields averaged only a little more than 200 jin per mu. The masses had wasted their labor and incurred costs for nothing, and they harvested 1.5 million jin less grain. Had government and communes been separate, with production being directed by someone who really understood what he was doing, this loss could have been avoided. The newly revised draft constitution's call for separation of government and communes will help the modernization of agriculture, and it will be heartily welcomed by rural grassroots cadres and the peasant masses.

Bajiao Commune CCP Committee Secretary Hu Kefa [5170 0344 3127]: Following communalization, the party, government, and communes actually ran everything, and the commune secretary was responsible for everything in a chaotic situation in which the party did not look after the party, the government did not look after the commune. If you said not to do something, everybody did it. If you said to take care of something, because of the unclear division of labor and murky responsibilities, it was never taken care of as it should have been. As a result nothing was taken care of properly. In order to comple promotion of double crops of rice, some years ago we commune secretaries would go separately into production teams around the time of qingming [around 5 April] to supervise the masses soaking of rice seeds, fearing lest the masses not plan according to plan. Where would such a commune secretary find time to give attention to ideological and political work and to build up the party? Now that the revised draft constitution provides for a gradual separation of government and communes, naturally I agree. Nevertheless, change must come gradually; it cannot come too fast. Following Liberation, small townships became large townships, and large townships became communes. In 1963, large communes became small communes; in 1969 administrative divisions were disbanded and combined with communes; in 1971, administrative divisions were re-established and small communes were designated. What with all the changes, no improvement or genuine vigor occurred in production until after the Third Plenary Session [of the 11th Party Central Committee]. This shows that it is not the names of organizations that is important but rather whether or not party programs and policies are correct. Right now the rural situation is better than at any period in the past, and the mass of peasants can say that they live in peace and are happy in their work. Yet they all have fear of "change," and no matter where the "change" comes from, it can cause some mental turmoil. Though communes are said not to be perfect, nevertheless they have been in being for more than 20 years. Cadre systems and farm management systems that have an impact on cadres and the masses should go through pilot projects, be carefully undertaken, and gradually promoted. Practical problems have to be solved well. For example, what is to be done with existing commune and brigade cadres? How will commune and brigade enterprises be managed, and will organizational and administrative cadres be set up below the township (or town) level? If not, will the country provide for expenses or will the masses have to chip in? All these problems have to be given all-around consideration and specific methods worked out. If they are not, problems will occur.

Wujiang Prefecture CCP Deputy Secretary Wang Yuesan [3769 2588 0005]: The combination of government and communes has meant that "superiors look after astronomy and geography while subordinates look after trifles such as chicken feathers and garlic skins," both administration and production being handled exclusively by superiors. When there are a thousand threads above and only one needle below, and everyone wants to thread the needle, the eye of the needle becomes blocked. The reason why commune cadres hurry and hustle, and are constantly weighed down with work lies here. The revised draft constitution stipulates establishment of township (or town) governments with a separation of government and communes, and this is favorable for the modernization of agriculture.

Following institution of production responsibility systems, work will devolve upon households and individuals, and the amount of work will be greater than formerly. How will a single production brigade with as few as 300 or 400 households or as many as 500 or 600 households be able to handle things with only three cadres? The biggest headache today is that a great many departments have been set up by superior authority; there are many meetings, numerous reports to write, and many documents to read too. When, in addition, government and communes are combined, it makes it difficult for subordinate echelons to cope. For example, apart from the county CCP Committee and county government, there are more than 30 first rank bureaus in our country, and if each bureau issues only one document a month, that becomes a large packet for those below. There is not enough time to read them all let alone implement them. Consequently, I feel that no matter how government and communes are divided, it is streamlining of the upper echelons, full staffing of the grassroots level, and strengthening of the frontline that is important. This is the only way to help production and to help work. I hope that when superiors are considering the separation of government and communes that they will give a lot of attention to the characteristics of government at the grassroots level, and that they will spend a little money and do everything possible to send some cadres excused from regular production duties to the grassroots to work at running grassroots government and cooperatives correctly. It does not do to have a heavy head and light feet, with an overlapping of organizations at the top and overstaffing, while at the lower levels people are hustling and bustling trying to cope. If this is the way things are to be, the separation of government and communes will not produce any results either. If central government organization streamlining is done quickly with good results to provide a good model for the lower levels, grassroots level government should also ride the east wind announced by the revised draft constitution for a revival, which would help the modernization of agriculture.

RENOVATION OF QING HE SEGMENT COMPLETED

Beijing BEIJING RIBAO in Chinese 25 Jul 82 p 1

[Article: "Work Finished and Water Flows on Lower Reaches Segment of Qing He Control Project After 4 Years Work Without Let Up. Solves Drainage of Water From City's Northwestern Suburban Towns and Draining of Waterlogging from Farmlands. More than 30,000 Civilian Laborers and Municipal Capital Construction and Machine Construction Contingents Fulfill Tasks Splendidly"]

[Text] After more than 4 years of arduous and unrelenting effort, the Qing He control project, which was begun to solve drainage in the city's northwestern suburban towns and to drain waterlogging from farmlands, was recently completed and water began to flow through the project segment in the lower reaches.

The Qing He is a main waterway for drainage of Beijing's northwestern suburbs that flows through the four prefectures and counties of Haidian, Chaoyang, Changping, and Shunyi. Because of many years neglect, many segments of the river have collapsed or silted and become choked with wild growth that seriously weakened its drainage capacity and affected normal life in the city and towns, environmental sanitation, and agricultural production. In 1978 the Municipal CCP Committee and municipal government decided to dredge this stream completely and bring it under control, as well as to set up a project command. Work formally got underway in September that year. This project, which was designed by the Municipal Water Conservancy Surveying and Design Academy planned to work from the lower reaches to the upper reaches, one section at a time. The newly designed waterway would be a little more than 4 kilometers shorter than the old one. Straightening of curves would require the dismantling or removal of 1,941 civilian houses and of industrial sideline enterprise units at 10 sites, plus the use of 3,500 mu of farmland. Time was short, the size of the project was large, and it affected many units. It was an arduous task. Comrades in charge of all departments concerned and in the four prefectures and counties proceeded with the overall situation in mind. After earnest exchange of views, they took action to overcome difficulties and finally satisfactorily solved most of the problems related to dismantling and removal of houses and taking over farmland for the project, assuring that the project would move along smoothly.

Once the project began, the prefectures and counties of Chaoyang, Haidian, Changping, and Shunyi assembled more than 30,000 civilian laborers to join in the struggle. The broad masses of civilian workers braved the scorching summer sun and faced the winter wind and snow, tramped through the mud, and put up with arduous conditions for splendid fulfillment of the quotas of earth to be removed assigned them individually. In order to reduce the intensity of labor and hasten progress on the project, in 1980 the project changed to a machine operation. The municipal water conservance, municipal government, and construction system's capital construction and machine construction contingents worked closely together and made concerted efforts to assure quality and progress on the project. The municipal government Second Company, responsible for building locks in the Qing He, lacked experience in water conservancy construction; however, they sought instruction and gained experience as needed from a fraternal unit and world strictly in accordance with design specifications. The quality of the locks they built met design standards and earned the praise of water conservancy departments.

Now dredging and renovation of an 18.47 kilometer section of the watercourse between the Beijing-Baotou railroad bridge andthe Wenyu He has been substantially finished, work having been completed on major structures. More than 29,000 trees have been planted on both banks of the new waterway to beautify the environment. As part of the construction, all units used the dredged sustained by nearby production teams.

He Qing He rises in the foothills of the Western Hills and flows past Qinglong Bridge, An He Bridge, Qing He Town, Sheajiafen, and enters the Wenyu He at Shaziying. It totals 28 kilometers in length, and two tributaries--the Wanquan He and the Xiaoyue He--flow into it. It is the main watercourse for drainage of several tens of thousan of farmland in the northwestern suburbs and for the residents, industrial plants and mines, government organizations, and educational institutions in most of the region. In 1958 the people's government organized forces to dredge this river. However, standards were very low at that time, and the stream has long since ceased to meet the ever increasing needs of urban construction. Furthermore, as a result of scouring and silting over the past 30 years, the river bed has become shallower and narrower, and the passageway throug rivers and locks along the river have become small and low, seriously impeding the flow and discharge of water. In years of torrential rains, farmlands have been innundated, villages, towns, schools, and enterprises flooded, some houses have collapsed, and communications have been cut.

This control project has included dredging of the main rivercourse, widening and deepening it, straightening out its curves, building of bridges and locks, and dredging of tributaries. Control of the main rivercourse was begun in the west at the An He lock in Haidian and extended to the Wenyu He, a total distance of 23.77 kilometers. More than 20 large bridges and locks were built, and small ones were built at more than 100 places. Following dredging, the main channel is 40 meters wide and is capable of carrying fllod waters at a rate of 486 cubic meters per second. During the rainy season, drainage of more than 30,000 mu on both banks can be assured, and in the northwestern suburbs, the cultural area, government organizations, industrial plants, and mines, as well as more than 20 villages and hamlets will be free from the threat of flooding. During water shortages, water can be provided via a diversion channel from the Miyun reservoir in Beijing, both watering farmlands and improving environmental sanitation.

PROVINCE MAKES GOOD SHOWING IN AGRICULTURAL QUOTAS

Fuzhou FUJIAN RIBAO in Chinese 26 Jul 82 p 1

[Article: "Procurement of Major Agricultural and Sideline Products in Province Increases Over Last Year. Launching of '432' Indoctrination to Enhance National Conception. Drop From Same Period Last Year in Quantities Procured of Live Hogs, Tung Oil, Honey and Charcoal Fuel. Departments Concerned Must Take Action for Active Organization of Procurement"]

[Text] This year, except for live hogs and tung oil, procurement of the province's major agricultural and sideline products was fulfilled very well. Statistics from units concerned showed that as of the end of June the province's plan quotas for spring grain and rapeseeds had been overfulfilled by 10.8 and 93.4 percent respectively. The total quantity of agricultural and sideline products procured by business and supply and marketing departments have overfulfilled annual procurement plans by 60.4 percent, a 5.4 percent increase over the same period last year. Quantities purchases of fresh eggs, tea, flue-cured tobacco, moso bamboo, and handmade paper increased substantially over the same period last year. Last year some places in the province showed a liberal trend in sales to the state of agricultural and sideline products, caring only for the interests of a part and neglecting state plan. Quantities purchased of some items fell for a time, impairing fulfillment of state procurement plans. Ever since last winter, as a result of transmitting and putting into effect the spirit of the provincial work conference on finance and trade and the launching in rural villages of "432" indoctrination, the socialist consciousness of the masses of commune members everywhere has been heightened and their national conception strengthened. In addition, assigned procurement base figures have been set everywhere for grain and oil, live hogs, eggs, flue-cured tobacco, tea, citrus fruit, handmade paper, dried bamboo shoots, tung oil, longans, and lichees. Various methods, including issuance of state requisition procurement quota notices, certificates showing sales of agriculture and sideline products, and the signing of procurement and marketing agreements, have been adopted so that centralized procurement and assigned procurement quotas will be gradually brought to bear on production units and peasant households to promote agricultural and sideline product production and procurement work. All finance and trade departments have set up network outlets as a convenience for the masses in making sales following the decentralized sales situation resulting from promotion of production responsibility systems.

This year quality of numerous agricultural and sideline products has been strikingly improved over last year. More than 320,000 dan of tea was procured throughout the province during the first half of the year, 8.7 percent more than during the same period last year, and quality was everywhere better than last year. In Sanming Prefecture, the quality rating for unfired tea leaf procured, and transported to tea plants for processing between January and May was 70.8 percent better than during 1981. Procurement of flue-cured tobacco in the province also overfulfilled annual plan by 3.9 percent. This included 66 percent high and medium quality tobacco, which was higher than the percentage in ordinary years. However, it must be noted that the quantities procured of agricultural and sideline products such as live hogs, tung oil, honey and charcoal fuel were less than for the same period last year. Departments concerned should take action to strengthen leadership and to organize procurement in an effort to fulfill or overfulfill procurement quotas.

GUANGDONG REPORT ON TYPHOON DISASTER

HK160829 Guangzhou GUANGDONG Provincial Service in Mandarin 2350 GMT 15 Sep 82

[Text] The 17th typhoon of the year hit the coast of Xuwen County yesterday and caused damage in varying degrees to a number of cities and counties in Zhanjiang Prefecture and Hainan Island. Inspired by the spirit of the 12th CPC National Congress, cadres and masses in the stricken areas actively resisted the typhoon attack and strove to reduce the damage caused by the typhoon to a minimum.

The typhoon hit the coast at Qianshan Commune, Xuwen County at about 0600 on 15 September. The typhoon's force was 7 on the Beaufort scale. The afflicted areas included Xuwen County and Haikang County of Zhanjiang Prefecture and Haikou City, Qiongshan County, Wenchang County and Qionghai County on Hainan Island. Vast areas in Zhanjiang, Foshan and Zhaoqing Prefectures generally had heavy or intermediate rainfall accompanied by squally showers. Due to its strong power, the typhoon caused damage in varying degrees to human lives, livestock, houses, crops and water conservation facilities.

Before and after the typhoon disaster arose, the CPC Zhanjiang Prefectural Committee, Hainan Regional Committee and Xuwen and Haikang County Committees sent a number of cadres to investigate the effects of the typhoon, express sympathy and solicitude for the people in the disaster areas and organize rescue work.

HAINAN ISSUES TYPHOON DAMAGE, PREVENTION CIRCULAR

HK180210 Haikou Hainan Island in Mandarin 0330 GMT 17 Sep 82

[Text] The commissioner's office of the Hainan Prefectural CPC Committee held an emergency meeting on the morning of the 15th. It listened to summary reports on the aftermath of the No 17 typhoon and flood prevention work. An urgent circular was issued at the meeting. It urged various areas to show the spirit of being fully responsible to the people. The areas must therefore quickly organize the masses of cadres to go deep into the midst of the front to take up any urgent matters and relief work following the typhoon.

The circular pointed out that the party committees and people's governments at all levels must realistically strengthen leadership over any urgent matters and relief work, They must immediately organize work teams to quickly get to disaster-affected areas to take charge of relief work.

The circular called on various areas to adopt the following effective measures to reduce damage from the typhoon:

1. We must do a good job of storing water to prevent hardships during the flood season. At present, most of the reservoirs in our prefecture are inadequately filled with water. All areas must take advantage of the rainy typhoon season to store more water to ensure an adequate supply for the early rice crop. A small number of areas with reservoirs which are adequately filled with water must make a point of fighting floods. Concerning those irrigation works exposed to danger, we must immediately organize forces to carry out emergency repairs.

2. We must try by every means to save agricultural crops and to reduce damage. At present, we must chiefly pay attention to draining off water and preventing waterlogging following the typhoon. The aim is to restore the affected crops to a normal state of growth. Those late paddies already ripe must be harvested without any delay. Concerning those lodged rice plants in an earing stage, we must strengthen management to guard against insect pests. Concerning sugar cane, pepper, coconut, coffee and other crops that have been lodged by the typhoon, emergency measures must be taken to save them. Those people who take advantage of the opportunity to steal or fell trees must be severely dealt with.

3. Concerning highways, postal and telecommunications facilities, electric power lines and other equipment damaged by the typhoon and floods, we must take emergency measures to ensure the smooth flow of traffic, the normal communication of information and the proper supply of power. This we can bring production and our lives back to normal. To show concern for the suffering of the people in disaster-affected areas, the civil affairs departments must make proper arrangements for the settlement of calamity-affected people and organize them to take up production to help themselves.

HAIKOU WORKS ON VEGETABLE OUTPUT AFTER TYPHOON

HK201422 Haikou Hainan Island Service in Mandarin 0330 GMT 19 Sep 82

[Summary] "The masses of vegetable-growing peasants in the suburbs of Haikou Municipality have taken emergency measures for the management and growth of vegetables. They are determined to quickly restore vegetable production and ensure the proper supply of vegetables for the market. The No 17 typhoon caused damage to vegetable production in the suburbs of Haikou Municipality. According to incomplete statistics, damaged vegetables reached more than 2,800 mu, affecting the supply of vegetables for the Haikou market. After the typhoon, the masses of vegetable-growing peasants took emergency measures in their rush to tend vegetable fields and to grow vegatables."

The Fantong Commune formed a plan for immediately growing more than 1,000 mu in vegetables to the production teams and peasant households. Immediately after the typhoon, the Liushuike Brigade of the commune mobilized its cadres and commune members to take care of the surviving vegetables, removing weeds, banking up the fields with earth and applying manure.

"In order to help the vegetable-growing peasants in the suburbs to tend vegetable fields and grow vegetables without delay, the seed company of Haikou Municipality has energetically tried to do a good job of providing seeds. The company has sent people to Guangzhou to purchase new vegetable seeds. The relevant department of the municipality has decided to allocate 50 tons of chemical fertilizer for the vegetable peasants to help them restore vegetable production."

The masses of vegetable-growing peasants do not forget the support rendered them by the state. They enthusiastically sell their vegetables to the state. The vegetable-growing peasants of Potou Brigade, which is well known for its production of fine seeds, are signing a purchase and marketing agreement with a vegetable company for the planned sale of 400,000 to 500,000 jin of fine seeds to meet market needs.

GUIZHOU 'RIBAO' EDITORIAL ON INCOME DISTRIBUTION

HK281316 Guiyang GUIZHOU Provincial Service in Mandarin 2315 GMT 25 Sep 82

[Guizhou RIBAO 26 September editorial: "Do a Good Job of Income Distribution by Carrying Out the Contracts Assigning Responsibility to Commune Members"]

[Summary from poor reception] The editorial said: "In the wake of the overall launching of work in the autumn harvest, the work of distributing income in the rural areas has been put on the agenda. After the system of contracting work tasks to individual households has been generally implemented, the key to promoting the work of income distribution in the rural areas lies in seriously carrying out the contracts of assigning work."

The editorial pointed out: "The central cardinal link of promoting income distribution is to adhere to the principle of three considerations, do a good job of ideological and political work, educate the peasants to establish the idea of cherishing the state and the collective, guarantee to fulfill the state's procurement quotas and the collective's retention quotas and advocate making more contributions to the state. In areas where there are bumper harvests, it is necessary to encourage the peasants to sell more grain produced in excess of quota and more grain at negotiated prices in order to assist the state's construction. Retention by the collective is an important aspect in the consolidation and development of the collective economy and the maintenance of the main economic body of the production teams. The contractor households must also work in accordance with the regulations of the contract and fulfill various essential retention quotas fixed by the production teams. This year, [words indistinct] it is necessary to pay attention to maintaining a certain amount for mutual funds and reserve grain. At present, our agricultural establishment is not strong enough to fight against natural calamities. An efficient method to improve such a situation is to speed up agricultural capital construction. (?In this year's) income distribution, production teams which enjoy more favorable conditions must retain an appropriate amount of money as funds for agricultural capital construction."

The editorial pointed out: "Carrying at the contracts of assigning responsibility to commune members and promoting income distribution is of great significance in examining the production responsibility system of contracting work tasks to individual households and speeding up agricultural development." Party committees at all levels in the rural areas must strengthen leadership and organize strength to do a good job in this work. First, it is necessary to achieve practical results in grain production and economic revenue. It is necessary to adhere to the principle of seeking truth from facts and refrain from making false reports on production. Second, it is necessary to work in connection with commercial allocation and further perfect the responsibility system of contracting work tasks to individual households. It is necessary to sum up experience in contracting work this year and grasp the signing of contracts or revising the contracts for next year's production. The higher levels must promptly organize strength to help production teams which have not undertaken production tasks this year. The higher levels must also help the production teams solve financial problems and problems of system. It is necessary to promote financial management of the production teams this year and next year, overcome confusion, achieve production increases and expenditure control, and improve the economic return.

HEILONGJIANG STATE FARMS--By 27 August, Heilongjiang's state farms had overfulfilled by 6.6 percent its 600 million jin wheat procurement task. [Text] [Harbin HEILONGJIANG Provincial Service in Mandarin 1100 GMT 30 Aug 82]

HEILONGJIANG FARM MACHANIZATION--Since the Third Plenum of the Party Central Committee, the mechanization of farm work has developed promptly in Heilongjiang Province. As of the end of 1981, the province had 78,000 large and medium-sized tractors, 42,000 handguided tractors, 18,000 combine harvesters and 11,000 motor vehicles for agricultural use. Total irrigation and drainage power was 1 million horsepower. Rural areas throughout the province now have a power total of 12.39 million horsepower, of which, 10.34 million horsepower are machinery power. [Text] [Harbin HEILONGJIANG Provincial Service in Mandarin 1100 GMT 31 Aug 82]

HEILONGJIANG FARM MACHINERY--According to the leading party group of the Heilongjiang Provincial Machinery Administration, the total amount of farm machinery increased in the recent 4 years equalled the total amount produced in the past 26 years, of which large and medium-sized tractors increased 130 percent, small tractors 250 percent and combines 800 percent. This province now has 3.3 million horsepower of tractors and each horsepower of machinery can manage some 28 mu of farmland. Except for applying additional fertilizer and weeding, about 50 percent of the farming operations are done by machinery. This indicates that Heilongjiang Province has changed its mode of farm operations from depending mainly on animal power to machinery. Farm machinery has become Heilongjiang Province's main force for agricultural production. [Text] [Harbin HEILONGJIANG Provincial Service in Mandarin 1100 GMT 5 Sep 82]

HEILONGJIANG FOOD INDUSTRY--Making use of its resources, Heilongjiang Province has become one of the state's major food production bases. It began to build bases to produce raw materials for food, such as beets, milk-producing animals, soybeans and minor oil-bearing crops. In 1981, the procured milk and dairy product output were both 100 percent more than in 1978. The food industry's share of the total industrial output has increased from 11.3 percent in 1978 to its present 15.2 percent. In the past 3 years, rural areas have increased their income by 1 billion yuan by growing beets, oil-bearing crops, tobacco and cows. Thanks to the developed food industry, the state earned 1 billion yuan of revenue and more than 70,000 people found jobs in the past 3 years. EFFECTIVENESS OF RURAL ECONOMIC READJUSTMENT EXPLORED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese
No 7, 1982 pp 6-11

[Article by Xue Jin'ao [5641 6855 7663] and Yan Yinglong [0917 5391 7893], Economics Institute, Jiangsu Provincial Academy of Social Sciences; "Jiangsu Province's Agricultural Readjustment and Agricultural Economic Effectiveness"]

[Text] Following the Third Plenary Session of the 11th Party Central Committee, what changes occurred in the course of the readjustment of Jiangsu Province's agriculture, what was their economic effectiveness, and how to judge objectively the economic effectiveness of agriculture in an area are all questions that deserve to be explored.

1. Readjustments and Changes in Jiangsu's Agriculture During the Past 3 Years

During the past 3 years Jiangsu's agriculture has been readjusted principally in two ways.

One was readjustment of rural production relationships and distribution policies. In accordance with several CCP Committee documents on agriculture, one after another rural economic policies were instituted that respected the self-determination of production teams, enlarged private plots, developed household sideline occupations, revived country fair trade, increased the value of agricultural sideline products, reduced or exempted agricultural taxes, and strengthened production responsibility systems. In 1978, the province had 5.15 million mu of private plots, which was expanded in 1980 to 5.34 million mu. In the 2 years of 1979 and 1980 peasant earnings for commune and brigade agricultural sideline products sold to the state that derived solely from increases in state procurement list prices and excess procurement prices amounted to more than 2.7 billion yuan, an average per capita increase of 53 yuan for the agricultural population. Production that had established agricultural production responsibility systems numbered 60 percent of the total number in 1978; at the end of 1981 they numbered 97.9 percent.

The second was readjustment of the rural economic structure. Not only was the agricultural production structure readjusted, changes being made in the ratios of grain and economic crops, the farming industry and the forestry, livestock, sideline occupation, and fishing industries, but the rural economic structure was also readjusted as regards all around dealings in agricultural sideline industries and development of the household economy, etc. During the past 3 years (1979-1981), the area sown to grain averaged about 91 million mu annually, an average of about 4 million mu less annual than for the previous 3 years (1976-1978). The area sown to cotton averaged about 9.4 million mu annually for the past 3 years, an annual average increase of about 600,000 mu as compared with the previous 3 years. The area sown to oil-bearing crops long remained at the low level of the 1950's, but during the past 3 years, it annually averaged about 4 million mu for an all-time high.

Readjustment of rural economic policies and the rural economic structure brought six major changes in their wake.

1. Hastening of agricultural development. For the past 3 years, Jiangsu's harvests have been one bumper, one lean, and one ordinary. The total output value of agriculture averaged an annual 14.6 billion yuan, a 32 percent increase over the 11 billion yuan annual average of the 3 previous years for an annual incremental 6.5 percent rate of increase, which was higher than the national 5 percent increase for the same period, and higher than the province's all time high 5.2 percent annual rate of incremental increase during the previous 29 years.

2. General increase in grain and economic crops. A comparison of the past 3 years with the 3 previous years shows a 12.4 percent increase in grain output, a 16.8 percent increase in cotton output, a 79.1 percent increase in oil-bearing crop output, an increase in output of other economic crops as well. Cotton output for 1979 and 1981 and oil-bearing crops output for 1981 broke the 10 million dan mark to create a new all-time high.

3. Increase in output value of forestry, sideline occupations, and fisheries as a ratio of the output value of agriculture. Output value of farming during the past 3 years as a ratio of the output value of agriculture declined from the about 65 percent of the previous 3 years to about 55 percent. Output value of forestry, livestock raising, sideline occupations, and the fishing industry correspondingly rose from 35 percent to 45 percent. In silkworm mulberry enterprises where no development had occurred for a long time, breakthroughs took place during the past 3 years as well, with silkworm cocoon output annually averaging 720,000 dan, a 35 percent increase over the 3 previous years, and more than the all-time high of 637,000 dan reached before the war in 1931.

4. Swift Development of Commune and Brigade Industry. For the past 3 years output value of commune and brigade industry has averaged an annual 10.44 billion yuan, more than double the 4.95 billion yuan average of the 3 previous years. Output value of commune and brigade enterprises was one-sixth total output value of industry for the province as a whole; income from it was one-half total income from the three tier economy of people's communes for the province as a whole; and tax revenues from it amounted to one-eighth tax revenues from industry and commerce in the province as a whole.

5. Shortening of the Gap In Production Levels Between One Prefecture and Another. The former low producing, poverty stricken Huaiyin Prefecture had

a grain output in 1981 totaling 7.6 billion jin, taking first place in the province. Its cotton and oil-bearing crops output increased by 15.7 percent and 2.2-fold respectively. Following 4 consecutive years of bumper harvests, Xuzhou Prefecture had a grain output in 1981 that broke the 7 billion jin mark. Yancheng Prefecture's cotton output totaled more than that of Nantong Prefecture, and Nantong Prefecture's silkworm cocoon output was more than that of Suzhou Prefecture.

6. Increase in Peasant Earnings and Improvement in Livelihood. In 1981, the total amount of distributions from the collective were 29.4 percent greater than in 1978 for an annual 9 percent incremental rate of increase. Distributions per capita averaged a 19 yuan increase over the previous year. This was the year of greatest increase in earnings for commune members in recent years. Peasant living standards improved strikingly, and consumption patterns changed. During these several years the ratio of food consumption decreased year by year and the ratio of consumption for housing steadily climbed. Annually between 800,000 and 900,000 houses were either newly built or remodeled, and the house construction area amounted to about 40 million cubic meters.

The following problems also appeared in the course of readjustment.

1. Reduction in Green Manure. Because of the overly fast development of the area planted to rape, some of the area that had been planted to winter green manure was taken over. In 1979 this area had been 13.49 million mu. By 1980, it had declined to 12.37 million mu; and in 1981, it again declined to 10.71 million mu. Reduction in the area planted to winter green manure not only adversely affected the source of fertilizer for autumn grain production and caused a delay in crop rotation, which was bad for increased output for the year as a whole, but more importantly the soil was nurtured but little and used a lot. This caused a decline in soil fertility, which was bad for long term increases in agricultural yields.

2. Decline in Hog Raising. Live hogs in inventory at year and numbered 23.56 million head in 1979 for an all-time high. Later on, as a result of changes in hog raising policies, most notably a reduction in collective hog raising, the number of hogs in inventory in the province at the end of 1980 fell to 20.88 million head, and in 1981 the number again fell, this time to 19.46 million head. Unless this declining trend is quickly reversed, it will have a bad effect on manure for use in agriculture, and on market supplies.

3. Successive Years of Reduced Grain Production in Suzhou Prefecture. In 1979 grain output for the prefecture totaled 8.2 billion jin, making it the all-time high year. In the next 2 years, as a result of natural disasters, reductions in the double-cropped rice area, and for reasons associated with work, the decline in output was fairly steep. In 1982, it fell to 6.4 billion jin, and in 1981 it again fell to 57 billion jin, which was lower than the 6.9 billion average of the 1970's. This very greatly hurt the province's supply of commodity grain to the state.

4. Increase in Quantity of State Grain Procurement and Reduction in Amounts Tendered. During the past 3 years state grain procurement has averaged 10.5

billion jin per year, a 61.5 percent increase over the 6.5 billion jin "three fixeds" state procurement quota, and a 12 percent increase over the average annual quantity of state procurement for the previous 3 years. But the quantity tendered to the state has declined. The annual average of unprocessed food grain tendered for the years 1976 to 1978 was 1.4 billion jin, but the average amount of unprocessed food grain tendered to the state for 1979-1980 was only 1 billion jin.

5. Continued Fairly Great Expenses for Agricultural Production, Which Began to Turn Around Only in 1981. A comparison of the past 3 years with the previous 3 years shows a 32.9 percent in total agricultural earnings and a 33.8 percent increase in total agricultural expenses, total expenses exceeding total earnings. Total expenses as a proportion of total earnings was 39.7 percent during the past 3 years, and 39.5 percent for the previous 3 years. They were slightly higher for the past 3 years than for the previous 3 years. Total distributable earnings by basic level accounting units in the province in 1981 increased by 9.6 percent over the previous year; total expenses declined 2.7 percent, and net income increased 18.7 percent for the beginning of a turn around.

Economic Effectiveness of Agriculture in Jiangsu For the Past 2 or 3 Years

The changes, problems, and pertinent data given above about Jiangsu's agriculture during readjustment represent only a general economic analysis and indicators related to it; it does not represent an analysis of economic effectiveness and indicators related to it. Economic effectiveness of agriculture means the comparison of the expenditure of labor (including the position held by labor) in the agricultural field and its production processes and the fruits of that labor, i.e., the frequently stated comparison of expenses and income. It is also a comparison of investment and output.

In the agricultural production process, numerous factors play a role in the economic effectiveness of agricultural production. The major ones are natural factors, economic factors, and scientific and technological factors. Apart from the natural factors, the major investments in agricultural production may be summarized as land, labor, and capital. The ultimate goal of agricultural production is to satisfy the needs of the material life and cultural life of all the people including the peasants. Therefore, in accordance with existing conditions, in the evaluation of the economic effectiveness of agriculture, five indicators may be applied, namely soil productivity rate, labor productivity rate, funds productivity rate, agricultural products commodity rate, and peasant benefits rate. In a society in which commodity production exists, not only can quantities of actual goods produced in agriculture be used as an indicator, but the amount of their value can also be used as an indicator. For convenience in making unified measurements, in evaluating the economic benefits of agriculture in an area, the value indicators should be paramount and the actual goods indicators ancillary.

1. Soil Productivity Rate. Soil is a basic means of production in agriculture for which there can be no substitute. It is both a natural resource and the production of human labor. It is a special form that embodies labor

that possesses very disparate characteristics of being a fixed asset created by human labor and being a means of labor. The soil's utilization value can never be completely depleted, and the soil's "value" can never be completely transferred. In agricultural production, the economic benefits derived from the use of living labor and embodied labor are determined, to a very great extent, by the level of soil utilization. In evaluating the economic effectiveness of agriculture in an area, it is necessary, first of all, to examine the effectiveness of soil utilization, i.e., to make a comparison of the land used with the fruits of labor. In order to reflect in an overall sense the state of utilization of agricultural land resources throughout the province to explain the labor created value per unit of land area used for agriculture, we used the two indicators of gross output value per unit of land area used for agriculture and net output value per unit of land area used for agriculture. The readjustments of the past 3 years in Jiangsu Province as reflected in economic benefits of land utilization have increased remarkably in comparison with the 3 years prior to readjustment. The land productivity rate for the 3 years of readjustment annually averaged a 17.3 percent increase, and the land net productivity rate averaged a 32.3 percent increase.

	Gross Output Value Per Unit of Land Area Used for Agriculture (Yuan)	Net Output Value Per Unit of Land Area Used for Agriculture (Yuan)
1976-1978 average figure	85.2	44.2
1979-1981 average vigure	99.9	58.5
Percentage Increase	17.3	32.3

Note: Gross output values and net output values shown in the table do not include output value of commune and brigade industry, and have been figured on the basis of 1970 constant prices.

2. Labor Productivity Rate. Development of agricultural production is determined not only by the total amount of labor invested in the production process, but also by the quantity (or output value) of farm products that a quantity of labor per unit of area is able to produce, i.e., the labor productivity rate. Because it is impossible in actual work to make a breakdown of working time, and difficult to calculate total amount of labor consumed, generally only the living labor productivity rate can be calculated. On the basis of extent statistical data, there is no way to separate the number of work days devoted to industry and the number of work days devoted to agriculture. For convenience in calculations, we used the indicators of output value, net output value and grain produced in a year per unit of agricultural labor, i.e., the "man year" indicator. Use of the indicator of net labor productivity rate holds extremely real significance for rational use of embodied labor and living labor, particularly in increasing the living labor productivity rate. During the past 3 years, Jiangsu's surplus agricultural labor has been further

shifted to commune and brigade industries, so the total amount of the labor force invested in collective agriculture (including forestry, livestock raising, sideline occupation and fisheries) has gradually declined. Comparison of 1981 with 1978 shows a 10 percent decline. As a result of implementation of the party's various rural economic policies and the increasing upsurge in the enthusiasm of producers, the labor productivity rate has strikingly increased. Weighted average calculations show an annual increase during the past 3 years as compared with the previous 3 years of 22.8 percent, 14 percent, and 16.9 percent respectively in output value, net output value, and grain production per unit of agricultural labor. That the rate of increase in output value per "man year" is higher than the rate of increase in net output value per "man year" shows that simultaneous with the increase in the living labor productivity rate during the past 3 years has been a greater investment of embodied labor.

	Agricultural Labor Productivity Rate		Agricultural Worker Net Output Rate, Net Output Value Per Worker (Yuan)
	Output Value Per Worker (Yuan)	Grain Output Per Worker (Jin)	
1976-1978 weighted average	446	2,055	295
1979-1981 weighted average	549	2,403	337
Rate of increase (%)	22.8	16.9	14.0

3. Funds Productivity Rate. As with other sectors of the national economy, the labor expended in the process of agricultural production is compensated by funds, and funds are an expression of the past value of labor. Therefore, the fund productivity rate indicator can reflect in an overall way the economic effectiveness of labor expenditure and funds expenditure. The reciprocal of the product rate for funds expended, i.e., cost per unit of product, is an overall indicator that is particularly widely used. However, since the fiscal statistical system currently in use in the country's rural communes and production brigades calculates only material expenses and does not calculate cost of completed goods, and does not calculate depreciation expenses on fixed assets in figuring the costs of materials, therefore, in judging effectiveness of funds utilization, only available data could be used to proceed from realities as they existed, with the selection of the indicator of net earnings per 100 yuan of production expenses invested. Calculations based on weighted averages show that the Jiangsu Province during the past 3 years effectiveness from the investment of each 100 yuan of production expenses was generally the same as for the previous 3 years, with just a slight decline, and very much lower than the all-time high level of 1957. This shows that in the process of agricultural production in Jiangsu Province, loss and waste of embodied labor continues very great, and that the speed of increase in net earnings cannot keep up with the speed of increase of embodied labor invested. However, looked at in other terms, despite the decline in effectiveness from investment

in agricultural production, as a result of the fuller and more equitable use of land and labor plus the increase in prices paid for agricultural products, net earnings from agriculture in the province during the past 3 years have averaged a 32.3 percent increase in absolute figures, which was no small rate of increase. Increase in the net income absolute figure provided the funds for expanding reproduction and for increasing peasant income, and increased the economic strength of communes and brigades.

	Average Annual Net Income (100 Million Yuan)	Average Weighted Net Income Per 100 Yuan of Production Expenses (Yuan)
1976-1978	47.1	154
1979-1981	62.3	152
1957	17.9	252
Percent Increase (+) or Decrease (-) Following Readjustment vs. Before Readjustment	+32.3	-1.3
Percent Increase (+) or Decrease (-) Following Readjustment vs. Before Readjus5ment	+246.1	-38.8

4. Agricultural Product Commodity Rate. Aside from satisfying peasant self-sufficiency needs, agricultural production also satisfies national economic development needs. Economic effectiveness of an area's social production may be measured by how well it satisfies society. The degree of which it satisfies society is determined by the quantity of agricultural commodities it is able to supply and by the commodity rate. Since the composition of agricultural production varies from place to place, the quantity of several kinds of agricultural commodities cannot completely portray the degree to which an area has become a commodity producer. For this reason, we based our measurements on actual commune and brigade earnings from the sale of agricultural products as a proportion of total earnings and the amount of commodities such as grain, cotton, oil-bearing crops, hogs, and silkworn cocoons provided by each member of the agricultural population. During the past 3 years, with the readjustment of the structure of agricultural production the province has made the most of its advantages in producing grain, cotton, oil-bearing crops, hogs, and silkworm cocoons. Output of oil-bearing crops has developed rapidly, an all around increase has occurred in the commodity output of principal agricultural products; the commodity rate has risen correspondingly, and the ratio of average annual income from commodities rose 5 percent over the average for the previous 3 years.

		Amount of Commodities Provided For Member of Agricultural Population				
	Ratio of Commodity Earnings to Gross Earnings (%)	Grain (Jin)	Cotton (Jin)	Oil (Jin)	Hogs (Jin)	Cocoons (Jin)
1976-1978	35.1	173	16.4	2.1	0.20	1.1
1979-1981	38.7	211	19.2	3.3	0.35	1.4
Percent of Increase or Decrease after Readjustment vs. Before Readjustment	+10.2	+22	+17.1	+57.1	+75	+27.3

Peasant Benefits Rate. Whether the peasants increase output and earnings is a major aspect of the economic effectiveness of agricultural production. Greater material benefits from production for the peasants is one of the goals of increased economic effectiveness of agricultural production. Thus, the level of peasant earnings is a major indicator for measuring an area's economic effectiveness in agricultural production. As a result of all around growth of agricultural production in the province during the past 3 years, plus state increases in procurement prices for agricultural products, commune member cash and grain ration distributions from the collective have increased fairly rapidly. In 1981 total amount of distributions to commune members were up 29.4 percent from 1978 for an annual incremental increase of 9 percent. Thanks to the correct handling of the proportional relationship between accumulation and consumption, commune member distributions as a ratio of total earnings increased during the past 3 years from the 47.5 percent of the 3 previous years to 48.3 percent. Peasant earnings derived from private plots and household sideline occupations increased most rapidly, and actual earnings levels were about 50 percent higher than the level of collective distributions. Peasant consumption goods purchasing power also increased remarkably. Average per capita consumption goods purchasing power increased by 62.7 percent in 1980 as compared with 1978.

	Commune Member Distributions as a Percentage of Total Earnings	Collective Distributions (Yuan per Person)	Grain Ration Distributions (Jin per Person)	Average Per Capita Consumption Goods Purchasing Power (Yuan per Person)
1976	47.3	79	456	*
1977	46.8	75	431	67.4
1978	48.3	94	462	77.7
1979	47.4	110	488	104.2
1980	46.0	106	476	126.4
1981	50.5	130		*

Note: * means statistical data lacking

To summarize the foregoing, economic effectiveness of agriculture in Jiangsu Province during readjustment has been good in an overall sense. Land productivity rate, labor productivity rate, agricultural product commodity rate, and peasant benefit rate have all increased.

Take the land productivity rate, for example. On the basis of the situation in Jiangsu Province where land is scarce relative to population, development of agricultural production requires even greater emphasis on intensive farming. Increase in land productivity rate means increase in the level of intensivity of farming. First must be further equitable use of existing cultivated land. In some medium yield and low yield farmlands in central and northern prefectures in Jiangsu, despite fairly substantial increases in output during recent years, a great potential still remains. Increase in yields from the fields of southern Jiangsu can be done through diligent summarization of experience and through perseverance in high yields from multiple cropping. Resumption of a rise in output there is entirely possible. Second is the need for full use of water surface resources. For the existing 5.4 million mu of water surfaces, all that is needed is further implementation of policies on water surface ownership and use rights and the province's output of aquatic products will be able to increase greatly within a short period of time for fine economic benefits. It is also necessary to strictly control illegal taking over of cultivated land. Strict procedures of examination and approval must be used for both the requisitioning of land and urban and town enterprises and for the building of buildings by commune and brigade enterprises or commune members to bring to a halt the unbridled taking over of land and use of land.

A look at the labor productivity rate shows that during the past few years, thanks to the shift of some excess rural workforces to industrial sideline production, the labor productivity rate has definitely increased. However, there is still a surplus of agricultural labor. For the province as a whole, the agricultural workforce is responsible for an average of about 4 mu of cultivated land per capita, but under prevailing conditions, each member of the workforce could be responsible for 6 mu of cultivated land. Extrapolation produces a surplus labor force of about 5 million for the province as a whole. If the labor productivity rate is to be further increased, it will be necessary to resolve further the problem of a transfer of surplus workforces. On the basis of experiences for the past several years, only when the thinking of leaders is clear and organization done well for the continued, planned, local shifting of surplus labor into economic diversification and into service trades can the labor productivity rate and agricultural products commodity rate be further raised and the peasants able to gain greater material benefits.

During readjustment, the agricultural funds productivity rate not only did not increase, but rather declined 1.3 percent as compared with the previous 3 years, and by 38.8 percent as compared with 1957. According to a survey of 57 production teams in six counties carried out by departments concerned, in 1979 losses incurred from failure to assure proper use of materials of various kinds used in agriculture and from unreasonable expenditures for entertaining ran at 6 percent for an average of 904 yuan per production team. A general increase occurred in material expenditures per mu of grain fields throughout the province. Figured on the basis of area sown to grain, quantity of seeds used in 1957 was 14.2 jin per mu; in 1965, 25.5 jin per mu; and in 1979, 44 jin per mu. Quantity of fertilizer used on cultivated land was 2.8 jin per mu in 1975, 18.8 jin per mu in 1965, and 133.8 jin per mu in 1979. Quantity of pesticide used on cultivated land was 0.2 jin per mu in 1957, 1.8 jin per mu in 1965, and 5.7 jin per mu in 1979.

In short, the key to increase in the economic effectiveness of agriculture in a region lies in all around development and comprehensive operations so that the structure of the rural economy will become rationalized. In addition, it is necessary to give attention to improving management of agricultural enterprises, being careful about economic accounting, and conserving expenditures of materials and labor. This is a weak link in Jiangsu Province's agricultural production and the place of emphasis in current efforts to increase the economic effectiveness of agriculture.

3. Several Problems Existing in Measuring Economic Effectiveness of an Area's Agriculture

1. Agricultural production is a combination of natural reproduction and economic reproduction. The essence of the natural reproductive process in agriculture is the transformation of energy and the material cycle between biological organisms and the external environment. In the process of agricultural production, investment of energy and materials must be done in accordance with natural laws and with adoption of proper techniques. This entails the constant maintenance of a balance in the exchange of materials and energy in the production process as the only way in which the amount of output of living things can become greater and greater, forming a benevolent cycle in nature. This requires maintenance of ecological balance. Conversely, if for the sake of immediate benefit people do things that overtax nature's ability to automatically revive and regulate, and that interfere with the normal functioning of the material cycle and energy transformation, in the end this will lead to decline in the quantity of living things, and the structure and function of the ecological system will become imbalanced. Consequently in examining the economic effectiveness of agriculture, one cannot simply look at a single year, but rather at 3 years, 5 years, or a longer period of time. Even more important is the need to study how to use specific indicators to analyze the ecological balance.

2. The process of economic reproduction in agriculture is a social production process repeatedly carried out by people in conjunction with certain production methods through joint work and exchange of work. In the process of economic reproduction, the material cycle and energy transformation change into exchange of social products, i.e., to be replaced by an exchange of the quantities of labor congealed in products to form a repetitive cycle containing the four links of production, distribution, exchange, and consumption. If any of the links of the economic reproduction process become blocked making impossible for a long period of time an exchange between quantities of labor, or a comparatively long imbalance between the agricultural economic sector and key elements, this will lead finally to atrophy and withering of the agricultural economy and to collapse of national economy. Consequently, to examine

effectiveness of the agricultural economy through analysis of only a single production link is not enough. An all around analysis of the four links of production, distribution, exchange, and consumption and their interrelationships is necessary. This problem awaits study for solution.

3. Accompanying development of production and readjustment of policies has been the appearance of many layers in the structure of the rural economy. Take the structure of production, for example. There is a production structure for grain and economic crops, a production structure for farming, forestry, livestock raising, sideline production, and fisheries, and a production structure for agricultural sideline industries. A look at the structure of ownership shows that although the collective economy is still dominant, the ratio of the household economy is steadily expanding. State-owned farms also have their own important position. Therefore, in examining the effectiveness of the agricultural economy, it is necessary to make a comprehensive analysis of farming, of agriculture, forestry, livestock raising, sideline occupations, and fisheries, and of agricultural sideline industries. It is also necessary to make a comprehensive analysis of the state-owned economy, the collective economy, and the household economy. Analysis of only a single aspect cannot reflect the overall situation of the actual economy. Statistical data is currently not complete in this regard, and specifications for making calculations not unified. This increases difficulties in making an all around and comprehensive analysis of agricultural economic effectiveness, and this requires accurate study and solution.

4. The agricultural economy is a major integral part of the national economy. Development of agriculture was to be done in accordance with socialist planned proportional economic laws; it must accurately handle the relationships among the country, the collective, and individuals, and take concurrent account of the interests of all three rather than be concerned with the interests of one. Today it is necessary to emphasize planned management of the country and to establish as an overall concept a mentality of "the entire country as a chessboard." Consequently, in examining agricultural economic effectiveness, one has to look at only an effectiveness of the micro-economy but even more so at the effectiveness of the macro-economy, and to unify the two. Under ordinary circumstances, the economic effectiveness of an area and the economic effectiveness of society are synonymous, but sometimes contradictions may occur. This becomes a question of who submits to whom. Without doubt the economic benefits of an area have to be subordinate to the economic benefit of the society at large. The problem requiring solution now is to find a unified method of evaluation and unified criteria for evaluation.

WAYS TO GROW LEANER HOGS EXPLAINED

Nanjing XINHUA RIBAO in Chinese 8 Aug 82 p 2

[Article: "Ways to Increase Live Hog Lean Meat Rate"]

> [Text] Editor's Note: After page 2 of the 30 May edition of this newspaper carried the news of Provincial Food Company experiments in "How To Make Hogs Grow More Lean Pork," many letters were received from readers asking for specific methods to make hogs grow more lean pork. In this connection, we have asked Comrade Chen Hongzhao [7115 7703 6856], doctor of veterinary medicine of the Animal Husbandry Bureau of the Provincial Department of Agriculture and Forestry, to provide a briefing.

A high or a low lean pork rate in live hogs results from the mutual role of internal and external factors. The major internal factor is the genetic traits of the breed. Because the genetic trait for lean pork rate is fairly strong, it is controlled by additive genes, so only by increasing the lean pork rate and purity of the hybrid parent pair is it possible to increase rapidly the lean meat rate in succeeding hybrid generations. Consequently, selective breeding to purify sows of local superior hog breeds in planned establishment of a lean pork line seems to be particularly important. However, increasing lean pork within a short period of time can be done at present only through economic hybrid methods with vigorous promotion of lean pork type hog hybridization for use. Hog breeds in Jiangsu Province are the fairly late maturing Huai hogs (including mountain hogs, kitchen hogs, and old Huai hogs) with a fairly high lean pork rate. Therefore, the crossing of Huai hogs with superior lean pork type boars should yield a 52 percent lean pork rate in their posterity. Moreover, because of their high fecundity rate and well known early maturation, Lake Tai hogs should achieve this level rapidly. It is necessary to run a ternary cross using "two foreign and one indigenous" breed of hog, i.e., use of a first generation hybrid sow resulting from the breeding of a local breed of sow with a foreign breed of boar for breeding with yet another breed of boar.

In considering external factors for improving the lean pork rate, most important is improving livestock feed, feeding techniques, and the right time for slaughtering. The element in livestock feed that most affects the lean pork rate is the protein level. Hog growth and development follows definite laws, and physiological properties such as bone, skin, flesh, and fatty tissues are differently balanced at different stages of growth and development. In the course of a long period of production experience, the Chinese people have summarized from experiences the laws of hog fattening as follows: "Small pigs grow bones; medium size pigs grow skin, large pigs grow meat; and fat pigs grow lard." Generally speaking from 3 to 6 months of age, the muscles grow most quickly. The main constituent of lean meat is protein; consequently, if full nutrients are given at this time, particularly compound feeds with a 70 percent coarse protein content, increase in the lean pork rate will benefit. During the large stage of fattened hog growth, limited feeding should be done, by which is meant restricting the energy concentration of feed and restricting the quantity fed to control nutrient density. This entails reducing the energy level of each kilogram of feed to about 2,800 kilocalories. The way of doing this is much feeding of green feeds to increase the proportion of ruffage. Limiting the amount of feeding entails reducing to 85 percent the amount of feed given in each feeding. This method of giving different levels of nutrients at different stages on the basis of the laws of hog growth and development, taking full advantage of lean pork growth heterosis, and controlling growth of fat meat, together with slaughtering at the right time are the only ways in which to increase the lean pork rate more rapidly.

In view of the specific circumstances of Jiangsu Province, in order to produce more lean pork, the following technical problems have to be solved:

1. Need for improvement in quality of dressed carcasses of all local hog breeds with increase in the lean pork rate being the main objective. Launching of experiments in the economic hybridization of combinations of lean pork type hogs, and use of economic hybridization (binary or ternary hybridization) for selection of the finest hybrid combinations that put on weight fast, consume little feed, and have both a high slaughter rate and high lean pork rate, and then establishing lean pork hog bases in suburbs to go into production rapidly.

2. Use of the province's superior breed breeding system to develop a specialized lean pork strain and to establish a breeding system for lean pork hogs. The genetic trait for a lean pork rate in hogs is a fairly strong one, and results derived from selective breeding are remarkable (the current degree of change in Jiangsu Province's lean pork rate for porkers being between 30 to 50 percent). There is a great difference in lean pork rate from one breed to another, and the individual variations between one animal and another within a breed are extremely striking, so this provides a good basis for our selection of lean pork type specialized strains. It also provides a foundation for future faster production of finer quality lean pork, and this is one of the basic measures for solving the problem of lean pork hog production.

3. Improvements in irrational feeding and care methods. An urgent problem of the moment is publicizing to the masses changes in feeding techniques so that the feeding of porkers with mixed concentrated feed is done during the early and mid periods of their growth, with limited feeding being done during

the last stages of hog growth. The emphasis on "fattening up" during the late stage of "building the frame" should be changed to increased feeding during the early and mid stages of hog growth and "withdrawal at the tail end," so that fattened hogs are not feed to exceed 200 jin.

4. Widening the source of supply of protein feeds. Jiangsu Province annually produces more than 1 billion jin of rapeseed cake and cottonseed cake, yet only about 13 percent of all of the "two cakes" are used for feed. Most of it is put on the fields for use as fertilizer, and this is a very great waste. When the cake residue from the pressing of oil is used as fertilizer, plants can use only 50 percent of its nitrates. Were it to be used as a livestock feed first, the manure then being used on the fields, nitrate utilization might amount to 90 percent. Protein is the material foundation for the growth of lean pork. If 100 jin of seed cake residue is in the compound feed used to raise a lean pork hog, requirements for growing lean pork will be substantially satisfied.

JIANGXI COUNTY GRAIN--From 1979 to 1981 Jiangxi's Yongxiu County delivered to the state 133.6 million jin of grain in excess of quota. This year it produced 115 million jin of early rice, setting new records in total output and per-mu yield. In 1981 total agricultural output value was 48 million yuan and revenues from diversified economy reached 17 million yuan. Per capita income of rural population rose to 108 yuan last year. The county has procured more than 50 million jin of early rice. [Text] [Nanchang JIANGXI Provincial Service in Mandarin 1100 GMT 9 Sep 82]

'LIAONING RADIO' ON MISUNDERSTANDING OF RESPONSIBILITY SYSTEMS

SK210517 Shenyang LIAONING Provincial Service in Mandarin 1100 GMT 20 Sep 82

[Station commentary: "Correctly Understand the Responsibility System of Signing Contracts with Households or Groups for Specialized Production and the Responsibility System of Letting Households or Specialized Groups Assume Full Responsibility for Farm Work"]

[Excerpt] In places where the responsibility system of signing contracts with households or groups for specialized production and the system of letting households or groups assume full responsibility for farm work are implemented, not only have commune members received benefits and asked for stabilizing and improving the systems, but also some cadres who went to the realities of life have clearly seen the advantages. Some comrades have put it well that the systems have boosted the enthusiasm of laborers and successfully displayed the superiority of the collective economy, and that they can promote both grain production and a diversified economy and can satisfy the needs of the livelihood of commune members and enable them to concentrate their efforts on the production of commodities.

Then, why is it necessary to call for correct understanding of the systems? First, because there are still some people who do not clearly understand or even have a bias against them. Some comrades always think that the systems mean retrogression and are not necessary in large, sparsely populated areas where the collective economy is substantially developed.

People with such an understanding should go to where the systems are enforced to see if peasants are really dividing up the land for individual farming or are taking the road back. If they earnestly investigate and study, it is not difficult for them to discover the essence of the issue. The systems are established on the basis that the major means of production belong to the collective. They are production responsibility systems allowing peasant households to do farm work individually and to take responsibility for their own profits and losses. They are contract systems under which unified management is conducted. Although labor organizations at all levels are divided and become smaller under the systems, commune members' material benefits are reflected more directly in the systems and their production enthusiasm is further aroused. The systems are a great leap forward in terms of development of production forces. They are far better than the equalitarian way of managing farm work. Despite serious drought this year, commune members who work under the systems combat the drought from dawn till dusk. They manage the lands, forests and orchards assigned to them as diligently as they do their private plots. This is a very good proof. Besides, we have only 2 or 3 years of experience in implementing the systems. The potential of the systems has not been fully displayed in this short period and our understanding of them is yet to be deepened.

Second, because some comrades often attribute current problems in rural areas--such as some commune members refusing to plant in accordance with state plans, some damaging collective property and natural resources and collective leadership being weakened--to the wrong causes.

These problems are objective existence. However, their existence is not the essence and main stream of current rural situation, nor the inevitable result of the systems. The resolution of these problems depends on nothing else than our efforts to educate commune members often on the consistency of the interests of the state, the collective and the individual and to imbue them often with communist ideas. [passage omitted]

BRIEFS

NEI MONGGOL COLD WAVE--According to the report of the Nei Monggol Autonomous Regional Meteorological Station, a cold wave from Central Siberia arrived at the northern areas of the region on the morning of 3 September. Thus, most areas in northern and eastern Nei Monggol will have sustained low temperatures in the days to come. On the morning of 9 September, most areas in Xilin Gol League, northern areas in Ju Ud League, northern areas in Jirem League, northern areas in Ulanqab League and northern areas in Bayannur League will have a frost; and southern areas in Jirem, Ju Ud and Ulanqab Leagues and eastern areas in Ih Ju League will have a light frost. [Text] [SK110731 Hohhot NEI MONGGOL Regional Service in Mandarin 1100 GMT 8 Sep 82]

NEI MONGGOL GRAIN OUTPUT--In the past, owing to the overconcentration of grain production and excessive reliance on the unitary way of operation, the ecological balance in Nei Monggol Region's Jirem League was destroyed and grain production developed slowly. After readjusting the agricultural structure and building many commodity grain bases since the 3d Plenary Session of the 11th Party Central Committee, the league's agriculture, animal husbandry and forestry have been developed in coordination. In 1981 the league hit records in production of grain, oil-bearing crops and sugar. Total grain output reached 2.2 billion jin, up 32.5 percent over 1977. Output of oil-bearing crops, increased 70 million jin, almost quadruple the 1977 figure. Commodity grain sold to the state totalled 530 million jin, topping the previous records. According to a tentative plan, in 1985, commodity grain bases in the league should build 4 million mu of fields with high and stable yield. Per-mu yield should average 400 jin. Total output should reach 1.6 billion jin and 600 million jin should be marketed to the state. [Text] [Hohhot NEI MONGGOL Regional Service in Mandarin 1100 GMT 7 Sep 82]

IMPORTANCE OF INCREASING REGION'S GROUND COVER STRESSED

Yinchuan NINGXIA RIBAO in Chinese 5 Aug 82 p 2

[Article by Ge Zhenhe [2047 2182 0678]: "Planting of Trees, Grass, and Bushes Is the Region's Most Important Agricultural Capital Construction"]

[Text] When the forest area of any country or any region amounts to 30 percent or more of total area and is evenly distributed, it can function in regulating climate, conserving water, holding back winds and stabilizing sand, conserving soil, purifying the air, and protecting the environment. It is a lever and a pivot for various ecological systems and the foundation for agricultural and livestock industry production.

Forests are an overall system composed of trees, bushes, and ground covers, the trees, bushes, and grasses having an inseparable inherent connection. However, each possesses its own charachteristics, and in the maintenance of ecological balance and providing products, each plays a mutually irreplaceable role.

Trees with tall trunks and well developed branches form the main body of forests. They play a great protective role when mature, and their economic benefits are high. Each hectare of broadleaf forest transpires as much as 2,400 to 2,800 tons of water in a growing season. This is 15 times the amount of evaporation from the same area of ocean, so the relative humidity of the air above a forested area increases by a general 7 percent. In some forest areas, average wind velocity is reduced by 20 to 40 percent and the frost-free period is increased by from 6 to 10 days. In addition, trees are the source of lumber for national construction and civilian use. However, trees have a long growing cycle and their environmental requirements are strict. If eroded areas are afforested with trees alone, it will be very difficult for them to play a role in breaking the wind and stabilizing sand and in conserving soil and water.

Though bushes and shrubs do not provide the useful material that trees provide, their production cycle is short; they are strongly resistant; and they present good prospects for growth even under harsh conditions. For example, feeder roots on sand willows [Salix gordejevii] number 60 to 100. One year's root growth for shandingzi [1472 0002 1311] is more than 800 meters long. Eight years growth of Caragana korshinskii will cover a

4 square meter area, will reduce by 73 percent sandy soil runoff, will reduce by 66 percent scouring of surface soil, and will restrain movement of 0.15 cubic meters of sand. Bushes and shrubs will generally grow in places in which the environment is harsh. Hedysarum scoparium, for example, is able to establish colonies on shifting sand; Chinese tamarisk can grow in heavily salinated soil with a 1 percent salt content; and Heci [7815 0459] frequently grows in swaths on deserts or rocks, and its roots have nodules. Chemical experiments have shown that the protein content of 1,000 jin of dried false indigo leaves is 23.7 kilograms, and the cruide fat content is 31 kilograms. Caragana microphylla is also rich in nutrients, and it makes a fine feed for livestock such as cattle, goats, and sheep. For this reason, people call shrubs "three dimensional prairies" or "grazing areas in the air." A single mu of bushes and shrubs is equal to 10 mu of grass. The branches and leaves of bushes and shrubs contains considerable amounts of nitrogen, phosphate, and potash, which are fine organic fertilizers.

Shrubs and bushes have an even greater advantage, namely their strong sprouting ability. When snipped to the ground, they are able to regenerate, and they live for as long as 70 or 80 years. Cut down once every 5 to 7 years, Hippophae ramnoides yields from 3,500 to 4,000 kilograms of firewood. This is of real value to southern mountain regions in the Ningxia-Hui Autonomous Region where fuel is in extremely short supply. In addition, many bushes have long, thing, and pliable branches, which make a fine raw material for plaiting. The dried branches of many bushes are strong and hard; they can be used to make paper, or to manufacture farm implements, furniture, and fiber board.

The multiple potential of bushes and shrubs has yet to be effectively utilized. Many bush and shrub seeds, for example, contain large amounts of fat; they are trees that are "sources of nectar." The fat content and the oily taste of aiyueyunzi [7093 2588 1926 1311] seeds, for example, rivals that of peanuts. The high oil content of the seeds of shiny-leaved yellowhorn [Xanthoceras sorbifolia] is well known to all. Mountain peaches and mountain apricot pits may be used for beverages, and they are also sources of supply for beverages made by food processing companies. Sichuan peppercorns may be pressed to yield oil and are a commonly used condiment. The parasitic saline cistanche [Cistanche salsa] and suoyang [3851 7122] on the fruit of Chinese wolfberry [Lycium chinense] and the roots of Baici [4101 5412] are rare medicinal herbs.

Herbaceous plants are small and weak, and people frequently underestimate their role and value. In fact, grass cover is also an integral part of the forest vegetation cover. Its stems and leaves grow luxuriantly; plants are dense; and the roots form a network, all of which plays a powerful role in keeping soil in place and improving the soil. For example, the granular structure of soil on which sweet clover has grown for a year may be increased by 20.6 percent, and within two years the soil's granual structure is twice as good as that of most farmland. Soil granules capable of holding water may amount to 3.0 percent of the total, and the rate of percolation in and out may increase 51 percent, runoff decline by 37.5 percent. and scouring of soil decline by 47.2 percent.

The following sentence may be used to explain experiences in establishing forest plant cover: "The trees rise to the heavens; the bushes fill empty space in the air; and alfalfa crawsl all over the top of the ground." Only when trees, bushes and shrubs, and grasses are used in combination can they function to advance and support the growth of each other.

The Ningxia-Hui Autonomous Region located on the northwest frontier lacks trees and forests. The forest cover rate is only 2.2 percent of the total land area, and the natural ecological system is extremely brittle. For long agricultural and livestock industry production have been held back by natural factors, and the life of the people is fairly hard. For this reason the planting of trees, grasses, shrubs and bushes is the region's most important agricultural capital construction. Only by undertaking capital construction of this kind can the region's agricultural economy genuinely make a new start.

The region has a complex topography, and the growing of a forest cover will require strict adherence to natural laws and economic laws. It will be necessary to carry out a program of adapting general methods to local situations, to build defenses against specific dangers, combine the planting of trees, bushes, shrubs, and grasses, and grow thm in strips, on tracts, and in networks to serve agricultural and livestock industry production and to serve the livelihood of the people.

The CCP Central Committee and the State Council have called upon the people throughout the country to increase the forest cover rate to 30 percent, making this a long term object of struggle in the building of socialism and in creating prosperity for posterity. Efforts should be made so that by the end of this century the country's forest cover rate will be 20 percent. For the Ningxia-Hui Autonomous Region this task will be most arduous, and the time is extremely short. We must prepare for the long haul while taking firm grip on the present; persevere in a scientific attitude, and strive to fulfill the strategic task of planting trees, grasses, shurbs and bushes so that the region will become a prosperous, burgeoining. and cultured one.

SHANDONG

BRIEFS

SHANDONG RAINFALL--From 30 August to 3 September there was successive rainfall from the west to east across Shandong Province. There was a 30-80-mm rainfall in Laiocheng, Dezhou, Humin, Taian, Heze, Jinan and Zibo Prefectures and Municipalities, as well as in most areas of Linyi Prefecture, eastern areas of Jining Prefecture and western areas of Weifang Prefecture. There was a 15-30-mm rainfall in Zaozhuang and Qingdao Municipalities, western areas of Jining Prefecture, eastern areas of Weifang Prefecture, southeastern areas of Linyi Prefecture and in northwestern areas of Yantai Prefecture. There was a less than 10-mm rainfall in southern and eastern areas of Yantai Prefecture. There are 45 counties in the province that have had a rainfall of over 50-mm, 21 counties with a 30-50-mm rainfall and 49 counties with a rainfall of less than 30-mm. This rainfall greatly contributes to the growth of late-autumn crops. [Text] [SK040744 Jinan SHANDONG Provincial Service in Mandarin 2300 GMT 3 Sep 82]

EASTERN SICHUAN FLOOD-FIGHTING EFFORT DESCRIBED

HK150727 Chengdu SICHUAN RIBAO in Chinese 6 Sep 82 p 3

[Report: "Responsible Person of Provincial Command for Fighting Floods and Drought Answers SICHUAN RIBAO Reporter's Questions on Flood-Fighting in Eastern Sichuan"]

[Text] Eastern Sichuan was hit by rainstorms from mid to late July this year. People throughout Sichuan Province have shown great concern for flood-fighting in this flood-stricken region. A responsible person of the provincial command for fighting floods and drought recently briefed a reporter of this paper on flood-fighting in the flood-stricken region.

Question: Can you tell me the extent of this year's rainstorms in eastern Sichuan?

Answer: Historical records show that the July-August period in eastern Sichuan has always been a dry period. However, from mid to late July this year, Daxian, Wanxian and Fuling Prefectures were hit by rainstorms and catastrophic torrential rains three times in succession. Generally speaking, the rainfall ranged from 400-600 millimeters during this period. Yuelai Commune in Shizhu County received the heaviest rainfall, amounting to 913 millimeters. As to the intensity of the rainfall, we can see that during this period, the heaviest hourly rainfall reached 100 millimeters and the heaviest daily rainfall reached 411 millimeters. These are very rare figures for this region.

This first rainstorms occurred from 15-18 July and primarily hit Tongjiang, Wanyuan, Xuanhan, Kaijiang, Daxian, Kaixian, Wanxian, Liangping, Yunyang, Zhongxian and Shizhu Counties and Municipalities. This was followed by more rainstorms and catastrophic torrential rains from 19-24 July and 26-29 July. The third rainstorms, which occurred from 26-29 July, covered a large area as compared with the first and second rainstorms. More than 190,000 square kilometers of land were hit by the third rainstorms. As a result, the daily rainfall in 25 counties (stations) [Zhan 4541] ranged from 100-279 millimeters. As a result of continuous rainstorms and catastrophic torrential rains, torrents of water rushed down the mountains, the rivers overflowed their banks and large areas of eroding hills, cave-ins and land slips were created. According to a preliminary investigation, there are more than 10 eroding hills, cave-ins and mud slips in the 3 prefectures.

Question: What are the conditions of those areas in eastern Sichuan which have been hit by the natural adversity this year?

Answer: Prior to the arrival of the rainstorms, meteorological departments had timely forecast the rainfall; all areas fully mobilized the masses to make many preparations against floods, and the masses and goods and materials in areas liable to be flooded were transferred to other areas without delay, thus reducing losses. Because the rainstorms broke with tremendous force and intensity and lasted a long period of time, they still caused great losses in people's lives and property; a total of 30 counties and municipalities in Daxian, Wanxian and Fuling Prefectures were hit by the natural adversity. A total of 22 counties (municipalities) in the 3 prefectures were severely hit by the natural adversity. They are: Wanxian Prefecture's Wanxian Municipality, Wanxian, Kaixian, Yunyang, Liangping, Zhongxian, Chengkou, Fengjie, and Wuxi; Daxian Prefecture's Daxian, Daxian Municipality, Xuanhan, Kaijiang, Pingchang, Quxian and Wanyuan; and Fuling Prefecture's Shizhu, Qianjiang, Fengdu, Dianjiang, Pengshui and Wulong. A total of 13 county towns, namely, Xuanhan, Dixian Municipality, Kaijiang, Daxian, Quxian, Wanyuan, Kaixian, Wuxi, Shizhu, Dianjiang, Fengdu, Pengshui and Qianjiang, and 184 farms and townships either suffered waterlogging or were submerged. The Shizhu County town was submerged three times. During the third submergence, the average depth of water was 1.5 meters; with the exception of a highland where the county CPC committee, the county people's government and the county people's armed forces department were situated. All other parts of the county town were submerged. The county towns of Daxian, Xuanhan, Quxian, Kaijiang and Kaixian were all submerged twice and suffered great losses. In the three prefectures, there are more than 6.23 million victims of the natural calamity, more than 210,000 people are homeless, more than 240,000 houses either collapsed or were washed away by the flood; over 7 million mu of farmland were hit by the natural calamity, 630,000 mu of cultivated land were destroyed by the flood, over 34 million jin of grain of the state and commune members and more than 20,000 domestic animals were washed away by the flood. The flood also destroyed 12,000 embankments, warehouses and weirs, 1,501 kilometers of irrigation ditches, over 300 hydroelectric power stations and nearly 1,000 highway bridges. The big land slip in Yunyang County's Baota Commune is 3 kilometers long and over 1 kilometer wide. Due to the flood, the houses, food stations, breeding farms, retail shops, district hospitals, commune clinics and cold storages belonging to 400 commune households and 29 production teams slipped away through the land slip and some of them slipped into the Changjiang River. Due to the emergence of a big land slip in Zhong County's Shaoxi Commune, 6 brigades and 24 production teams suffered the following losses: nearly 2,000 mu of farmland were damaged; 758 houses belonging to 244 households were destroyed, thus making 1,114 people homeless. In the fourth Tuoxiang Brigade, Hujia Commune, Yuexi District, Kai County, more than 300 mu of land subsided; and 310 houses owned by a commune unit, a supply and marketing cooperative, 10 units and 16 commune households all subsided. It is true that the scale of this year's flood in eastern Sichuan was smaller than the large-scale flood in the province last year. However, as far as eastern Sichuan is concerned, this year's flood has created very serious conditions.

Question: What kind of flood-fighting tasks have been carried out and what achievements have been scored by the flood-stricken region? What is the current situation?

Answer: You have recently issued separate reports on the flood-fighting work in the three prefectures. In short, following the emergency of this flood, the stricken region's party committees and government at all levels quickly adopted effective measures in leading the struggle against the flood. Responsible comrades of party committees and governments at all levels promptly hurried to the flood-fighting front, and directed and organized work of saving the flood-stricken masses, the goods and materials of the state and the masses' property. PLA commanders and fighters also actively participated in the flood-fighting struggle, thus promptly saving many people who were beseiged by the flood. Party committees and governments at all levels promptly sent powerful work teams to the flood-stricken areas to help promote work there. In line with the principle of self-reliance and the principle of offering mutual help among the masses and collectives with the support of the state, they organized and mobilized the masses to quickly carry out the struggle to provide for and help oneself by engaging in production and to rebuild their villages and towns. At present, proper arrangements have been basically made for the livelihood of severely afflicted households, flooded crops have been salvaged, field management has been strengthened and some late-autumn crops have been planted. The great majority of flood-stricken factories, mines, enterprises and shops have restored production and resumed business.

All areas have adopted measures to readjust the economic policy toward severely afflicted communes and brigades and have mobilized the masses' enthusiasm for flood-fighting and for providing for and helping themselves. For example, Xuanhan County, the most severely afflicted county in Daxian Prefecture, has reclaimed and restored more than 22,000 mu of cultivated land which are all sown to sweet potatoes, taros, vegetables and other late-autumn crops.

Question: What measures have been adopted by the provincial authorities to assist the people of the eastern Sichuan's flooded areas in restoring production and rebuilding their villages and towns?

Answer: The provincial CPC committee and the provincial people's government have attached major importance to the flood in eastern Sichuan. On behalf of the provincial CPC committee and the provincial government, Provincial CPC Committee Secretary Yang Rudai and Provincial Vice Governor Liu Haiquan went to the flood-stricken areas to express sympathy and solicitude for the people there and to direct the flood-fighting work. Moreover, the provincial CPC committee and the provincial government sent three groups to the flood-stricken areas to express sympathy and solicitude for the people there and to assist them in their flood-fighting. They also held several meetings of responsible comrades of provincial organs, mobilized all departments to tap the potentials of goods and materials and financial potentials, tried in every possible way to help the flood-stricken areas, and allocated a lot of chemical fertilizers, steel products, cement, gasoline, diesel oil, kerosene and relief funds to the flood-stricken areas. Moreover, the provincial agricultural bank promptly granted subsistence loans to victims of the flood. At present, some goods and materials are still being allocated and transported to the flood-stricken areas. The loving care shown by the provincial CPC committee and the provincial people's government is a great inspiration to people of the flood-stricken areas.

Under the leadership of party committees and governments at all levels, people in the flood-stricken areas have bravely waged an arduous struggle for more than a month and have scored initial achievements in flood-fighting. In today's flood-stricken areas, the masses are in a stable mood, prices remain stable, public order is fine, and the fervent upsurge in providing for and helping oneself by engaging in production is in the making. They have this fighting slogan: Flood-free areas try in every possible way to achieve a greater production output; areas hit by minor floods try in every possible way to realize a production increase; areas hit by severe floods try in every possible way to reduce losses to the slightest degree; and great the victorious opening of the 12th CPC National Congress with achievements in fighting floods and reaping bumper harvest.

'SICHUAN RIBAO' ON ENRICHING RURAL AREAS

HK241056 Chengdu SICHUAN Provincial Service in Mandarin 0030 GMT 24 Sep 82

[Excerpts of SICHUAN RIBAO commentator's article: "Get Mobilized and Create a Situation of Going from Poverty to Affluence"]

[Text] SICHUAN RIBAO 24 September carried a commentator's article entitled "Get Mobilized and Create a Situation of Going from Poverty to Affluence" on how to enrich the rural areas in Sichuan as soon as possible.

The article said: The 12th Party Congress has taught us to strive for creating a new situation in all fields of socialist modernization. The great goal put forth by the congress concerning economic construction is to strive to redouble the gross national industrial and agricultural output in the 20 years from 1981 to the turn of the century, under the premise of incesantly improving economic returns. In a short time to come, in accordance with the actual situation of our province's agricultural front, we must realize the target of struggle formulated by the provincial CPC committee. In the next 5 years we must strive to increase the total grain output by an average of 2-3 billion jin each year and the per capita income of people in the rural areas by 20-30 yuan. We must increase the province's total grain output to 80 billion jin and the per capita income of rural inhabitants to 200, 300 and 400 yuan, respectively, in one-third of the production teams. In the next several years to come, rural party organizations at all levels must comprehensively implement the spirit of the 12th Party Congress, do a better job of ideological and political work, and mobilize the masses to proceed from poverty to affluence, thus laying a solid foundation for realizing the strategic goal of economic development in the coming 20 years.

The commentator's article said: The provincial CPC committee work meeting held in June decided to accelerate the goal and measures for enriching the rural areas in our province. The decision by the provincial CPC completely complies with the strategic decision made by the 12th Party Congress concerning economic construction for 20 years and is an important step in implementing the national decision in our province.

Whether or not the realization of the target of struggle for the next 5 years, decided upon by the provincial CPC committee, can be accelerated is an important question which must be answered in ideological and political work in the rural areas. During the past several years, agricultural development in our province has been relatively fast and the rural situation has become more promising. However, the understanding of certain grassroots cadres is still backward. Ideologically speaking, they do not quite understand the new situation after implementing the production responsibility system, and some of their work is not on the right track. In addition, they do not have an adequate understanding of the role of the great readjustments such as the readjustment of production relations. Thus, it is necessary to help them correctly understand, by means of ideological and political education, the relationship between realizing the targets of struggle for a fixed time to come and the target of carrying out economic construction for 20 years. We must make them understand that by probing in many ways into the past 20 years since agricultural collectivization, we have finally worked out the production responsibility system, agricultural management and methods of distribution which on the one hand adhere to the socialist path, and on the other hand, suit the level of development of the productive forces and the level of awareness of the peasants. As the central leading comrades pointed out, the rural situation of implementing the production responsibility system is very promising and is in the ascendant.

Recently, the provincial CPC committee introduced 20 examples of increased production in bringing about affluence in rural areas in the northern part of Sichuan. These are persuasive examples of the implementation of the production responsibility system, emancipating the productive force and giving play to the initiative of the collective and the individual.

The commentator's article also pointed out: In order to guarantee the realization of the target of struggle put forth by the provincial CPC committee, we must still continue to encourage certain peasants to take [words indistinct] into consideration and strive to enrich by relying on the collective and on labor, thus benefitting both the collective and the individual. Simultaneously, we must still vigorously popularize the policy of "three considerations," popularize the principle of taking planned economy as the key and market regulation as the supplementary, and educate the peasants to be concerned with the interest of the state and the collective, thus properly handling the relationship between the interest of the state, the collective and the individual.

The commentator's article stressed: At present, it is necessary to strengthen education in the "two no-changes" and help the grassroots cadres, on the basis of summing up the experiences of the masses, gradually perfect the agricultural [words indistinct].

In conclusion, the SICHUAN RIBAO commentator's article said: Carrying out ideological and political work in the rural areas, we must firmly grasp the building of socialist civilization focusing on communist ideology, enabling the broad masses of commune members to proceed along the socialist path and become true [words indistinct] and socialist peasants who have cultural cultivation and who observe discipline.

NEED FOR LONG RANGE PLANNING STRESSED

Chengdu SICHUAN RIBAO in Chinese 16 Jul 82 pp 1,2

[Article by Commentator: "Do a Good Job of Longrange Planning for Rural Construction"]

[Text] Development of the rural economy and hastening the construction of mountain regions requires accurate programs, policies, and measures; it also requires formulation of longrange construction plans. The recently convened Provincial CCP Committee work conference required all jurisdictions to come up with well defined 5 to 10 year targets to be achieved in rural economic and social development to give the masses something to strive for.

As long ago as the 1950's Comrade Mao Zedong personally presided over the formulation of long range plans such as an outline for national agricultural development. He said: "This plan is useful as a longrange objective so that people's vision will not be limited to the steps they are taking at a particular moment." Today we have both central government programs and plans, society is stable; people have many ideas, and what is urgently needed is a clear and fairly longrange concrete target toward which the masses may be mobilized for struggle. The Provincial CCP Committee has proposed that for the next 5 years Sichuan Province should achieve an annual average increase in total grain output of from 2 to 3 billion jin, and that rural commune member income (including income from collective distributions, wages from commune and brigade enterprises and income from rebates, and net income from household sideline occupations) should average annual increase of 20 to 30 yuan so that after 5 years of effort, the province's total grain production will stand at 80 billion jin, and average per capita commune member earnings as derived from the three aforementioned sources in a production team will be 200 yuan, 300 yuan, and 400 yuan, with the next step being to strive for a national production gross output value averaging $1,000 per capita. These several major economic norms collectively reflect the level of rural economic development. Naturally, our goal is to build flourishing, prosperous, democratic and civilized new socialist rural villages. The content of longrange planning has to be somewhat all encompassing and the building of the two civilizations [material and spiritual civilization] has to be considered part of it. The Provincial CCP Committee's raising of such an objective is extraordinarily necessary, and it constitutes an extremely great encouragement for the cadres and masses of the entire province. We realize that during the past several years many places, communes, and production brigades have made plans and that after 3 to 5 years of effort, production has developed very rapidly and the livelihood of the masses has improved. Though some started a little late, they have taken the first steps and the future looks hopeful. Some, however, have yet to make any longrange calculations; they lack much will; they do whatever is required; and the years come and go. Practice has shown there is a very great difference in zeal for work and economic results when there is planning and when there is not. Even when plans are a little rough, they are better than none.

Is realization of the foregoing conception possible? After investigation and study, discussion with the masses, item by item calculations about local grain production and major economic diversification, many prefecture and county leadership comrades and prefecture and commune cadres believe that though the task is an arduous one, with effort it is entirely possible to achievement. They think ahead and are full of confidence. However, there are also a small number of comrades who see difficulties as being more numerous, and their confidence is not that great. One major reason is that our comrades' thinking is not broad; they do not have many ways of doing things; they are seriously prone to doing things in conventional ways; and they do not know how to use ingenuity to broaden avenues. We might organize our comrades to look a little more at advanced models and to seek instruction from the masses to widen their horizons and strengthen their confidence. Though conditions differ from place to place, everything depends on human effort and one has to make the most of conditions as he finds them. Everyone has his own strengths and each person walks his own path. The crucial point lies in the level of our leadership and the state of morale.

Formulating longrange plans requires not only a battle objective but also requires vigorous measures, based on local natural and human resources, the adaptation of general methods to specific situations, the use of strengths and the avoidance of weaknesses, and making the most of advantages. In the field of grain production, it is necessary to proceed from the basis of a fixed grain sowing area to organize a scientific attack to increase yields per unit of area and to carry out needed agricultural capital construction, to strengthen ability to withstand natural disasters, and to assure steady annual increases in total grain output. Since Sichuan Province has a large population relative to available land, sole reliance on grain will not make it possible to make a new start and become prosperous. While taking a firm grip on grain production, full use will have to be made of the province's bountiful natural resources and the mass workforce for vigorous development of economic diversification and industrial sideline occupations. The potential in this regard is very great. Rural average per capita earnings increases of 20 to 30 yuan depend primarily on this. Development of economic diversification requires bringing into play the enthusiasm of both the collective and commune members individually. The opportunities that commune member household sideline occupations provide are very great, and even more can be done in the field of collective economic diversification and industrial sideline occupations. Today, in a substantial number of production teams, nothing has been done about economic diversification, or else a start is just being made. Commune member earnings are very low. The main reasons are: first, no rational utilization of resources and human talent; second, insufficient perfection of production responsibility systems. Tasks that should be done by specialists have not been specialized, and tasks that should be performed jointly are not being performed jointly; third, leadership teams have problems of one kind or another. Leaders at higher level should give them pertinent assistance in solving these problems so that economic diversification can get underway.

Planning definitely requires proceeding from realities and following the mass line. Provincial and prefectural plans provide a rough guide, but most important is that from the county on down, particularly in communes and brigades, concrete planning and implementation be done. While giving attention to current production, individual communes and production brigades should simultaneously arouse cadres and the masses to full discussion, tap the potential resources, human talent and workforces provide, broaden production avenues, single out key items, and propose concrete objectives and measures for local communes and brigades so that plans will embody the desires of cadres and commune members and become converted into their conscious actions. Positively there can be no superiors subjectively coming up with standards that are imposed on those below. In the processing of formulating production plans, Shigang Commune in Wanyuan County launched three checks and three sees: First was to check the strength in resources of local brigades and to see how to use them sensibly; second was to check on skilled craftsmen and surplus workforces and to see how to make the most of the special abilities of human talent; and third was to check the potential for production of grain and economic diversification and to see how to tap it fully. Through such activities, they expanded their horizons, found avenues, and opened up new sources of revenue, this year adding an additional eight or nine production items and increasing earnings over original plan by more than 200,000 yuan. Their experience is good and merits promotion.

When formulating plans, cadres and the masses have to be taught to rely on increases in production to become prosperous and to become prosperous through labor, to institute a program of taking the planned economy as the key link with market regulation being supplementary, and to be concurrently concerned with the interests of the country, the collective, and commune members individually. While increasing individual income levels, it is necessary to make a greater contribution to the country, to assure required collective withholdings, and not to engage in dishonest practices. Longrange planning has to be linked to surveys of natural agricultural resources and to the zoning of agriculture with everything being done in accordance with natural laws and economic laws. After longrange plans have been formulated, revisions will have to be made through annual plans and their translation into reality, as well as through practice so that they better accord with reality. Once a plan has been devised it must be persevered in, followed to the full, and instituted step by step so that one's own locale changes year by year.

'SICHUAN RIBAO' DEVOTES NEW COLUMN TO RURAL PROSPERITY

HK28k3k9 Chengdu SICHUAN Provincial Service in Mandarin 0830 GMT 26 Sep 82

[Excerpt] On the opening of a new column on how to bring prosperity to the rural areas in Sichuan Province as soon as possible, Sichuan RIBAO published an editorial note today on the front page.

The editorial note says: In order to implement the spirit of the 12th CPC Congress on our province's agricultural front, to encourage the vast number of cadres and the masses to contribute their initiatives and suggestions and devote their efforts to speeding up the development of agricultural production with one heart and one mind, to realize the aim of increasing production and income in rural areas in 5 years put forth by the provincial CPC committee, and to materialize the goal of struggle for the next 20 years before the turn of the century put forth by Comrade Hu Yaobang in his report to the 12th CPC Congress, our newspaper now specially opens, at the suggestion of the provincial CPC committee, a new column to start off the discussion on how to bring prosperity to the rural areas in Sichuan Province as soon as possible.

This discussion is started today, the editorial note says, the general ideological guideline for this discussion is to adhere to the spirit of the 12th CPC Congress and the party's principle of being practical and realistic and proceeding with everything based on the actual situation, to give full play to the spirit of boldly blazing new trails in carrying out rural economic reform, to further emancipate the productive force and to mobilize all positive factors to increase production and income in rural areas so as to help the peasants to get rich as soon as possible and make more contributions to the state. BRIEFS

TIANJIN CHANNEL PROJECT--On 6 September, the Tianjian Garrison District held a mobilization rally to mark the initiation of digging the last section of a channel to divert Luanhe River water to Tianjin City. All commanders and fighters attending the rally pledged to complete the project by 15 June 1983 in response to the socialist modernization set forth at the 12th Party Congress. Wu Zhiyuan, deputy commander of the Tianjin Garrison District, spoke at the rally. [Text] [Tianjin City Service in Mandarin 0030 GMT 8 Sep 82 SK]

XINJIANG

BRIEFS

XINJIANG WORKERS' LIVELIHOOD IMPROVES--The investigation of the living conditions of 220 worker households in Urumqi, Karamay, Yining and Kashi Municipalities has revealed that the average per capita income of workers' households per month in 1981 was 37.18 percent more than in 1979 and that the average per capita income for living expenses increased by 13.6 yuan, an increase of 31.13 percent. The investigation has also revealed that in the first half of this year, for every 100 households, there were 7.73 bicycles, 2.71 sewing machines, 11.82 watches, 9.09 radios, 16.37 television sets, 4.55 recorders, 0.91 cameras and 6.36 electric fans more than in the first half of last year. The workers' living conditions have also improved. [Text] [Urumqi XINJIANG Regional Service in Mandarin 1300 GMT 6 Sep 82 HK]

XINJIANG GEOLOGICAL WORK--Since the 3d Plenary Session of the 11th CPC Central Committee, Xinjiang Region has achieved outstanding results in geological work. Over the past 3 years, the region has discovered 48 ore deposits and points and built 13 large- and medium-sized reserve prospecting bases. After further working and expanding shafts, 11 old mining areas have increased their workable reserves. Since 1980, the region has discovered a large gold deposit and a sulphur deposit. Over the past 3 years, geological workers in the region have discovered a number of gem and jade production places in south and north Xinjiang. Moreover, they have actively conducted surveys to serve agriculture, animal husbandry, industry and urban construction in the region. I. GENERAL INFORMATION

SOUTH CHINA REAPS BUMPER EARLY RICE HARVEST

OW171213 Beijing XINHUA Domestic Service in Chinese 0705 GMT 11 Sep 82

[Text] Beijing, 11 Sep (XINHUA)--Peasants in south China's early rice-producing areas have reaped a bumper harvest this year, thanks to their efforts to overcome the effects of heavy rain and waterlogging.

According to information released by departments concerned, it is estimated that the total output of early rice for this year has hit an all-time high, topping the 1981 figure by 3 billion jin or a little bit more, despite a reduction of 1.7 million mu in total acreage of this crop from the last year's total. Among these areas, Guangxi, Guangdong, Hubei and Hunan registered bigger margin increases in output while Anhui and Shanghai also increased some. Early rice output in Zhejiang and Yunnan remained at the 1981 level, and in Jiangsu, Jiangxi, Fujian, Sichuan and Guizhou it decreased slightly due to serious natural disasters.

This year's bumper harvest of early rice was achieved through efforts to stabilize and improve the various production responsibility systems, popularize agricultural science and technology and surmount the effects of various natural disasters. Guangdong Province planted 2.8 million mu of hybrid rice this year and the average per-mu yield topped that of the conventional variety by more than 100 jin. Many households engaged in early rice production on contract even registered per-mu yield of over 1,000 jin. The early rice-producing areas were hit by typhoon and torrential rain on many occasions during the crop planting and harvesting period in May through July. Crop damage was reduced to the minimum, thanks to efforts made by the peasants to help each other in their united struggle to drain the flooded fields, save the crop and exercise meticulous care in field management and harvesting. Bigger margin increases in early rice production were realized this year by areas of usually lower yield in output and areas not affected by natural disasters. All these factors made a nationwide bumper harvest of early rice possible despite the many natural calamities.

RURAL ECONOMIC OUTPUT, DEVELOPMENT DISCUSSED

HK020436 Beijing CHINA DAILY in English 2 Oct 82 National Day Supplement p 5

[Article by Du Runsheng, director of the Rural Policy Research Center of the CPCCC Secretariat: "Flexible Policies Are Key to Rural Wealth"]

[Text] The Chinese countryside is undergoing a period of reform which finds expression in two ways. One is the change in cooperative economic production methods. The other is the adoption of a diversified economic development policy.

A job-responsibility system also appears within the cooperative economy in the countryside to bring forth the initiative of peasants towards production and to strengthen the collective economy.

However, land still belongs to the state. The administrative organizations of the cooperative economy jointly manage and coordinate agricultural work like farmland planning, irrigation systems, adoption of large agricultural machinery, and production planning.

At the same time, organizations encourage the enthusiasm of the peasants towards production by allocating land and farm tools to them under job-responsibility contracts but letting them run their own production. The organizations share the products with the peasants according to the contracts.

The contractors share the collective expenses according to the quality of their individual plots and get what they produce. Collectively-owned businesses and sideline occupations are assigned to the peasants after agreement on output, investment and profits.

The agricultural cooperative system thus involves management at several levels. The unified management of brigades and communes meshes with the individual management of peasants. This has changed production methods. Under the general plan, each peasant household can arrange its yearly work as it wishes and family members can cooperate with each other in their work.

Productive Method

This method of production may seem backward compared with centralized management and general distribution of manpower, but it suits the production forces in the countryside and so promotes production.

It takes into account the interests of individuals and overcomes the shortcomings of egalitarianism in work payments. This method also gives peasants freedom in production, removing the likelihood of confused orders and other inefficiencies. It combines power, responsibility and individual interests, fanning the peasants' enthusiasm towards agricultural production.

In a developing country like China, socialist reform in agriculture is sure to be a long process. Since economic conditions in each part of the country are different, agricultural management must also take different forms during a certain process.

It will get us nowhere to go after equality in agricultural management. Therefore, any production method that can lead peasants to socialism should be adopted and encouraged.

China is a big country with a large population but a rather small amount of farmland. It is difficult to make the 800 million peasants rich quickly with limited farmland. For a long time we emphasized only the importance of grain production and neglected other crops. As a result, lots of forests and grassland were destroyed, and many lakes were filled in to produce grain. It did not increase the output of grain production but seriously broke the ecological balance.

In recent years, the party and government have called on peasants to develop agricultural production comprehensively. Apart from grain and cash crop production, animal husbandry, forestry and all forms of household sideline occupations, peasants have also established enterprises which process farm produce and have developed other small industries which require manpower rather than machines. They also set up service and commercial transportation businesses.

Diversified Economy

"We must positively develop diversified economic activity and pay close attention to grain production" is a slogan put forward by the party Central Committee and State Council. So we should develop mountainous or hilly areas, grassland and lakes by using our large labour force. This will have many benefits, raising peasants' income, accumulating agricultural funds, improving the diet of Chinese people and reducing the pressure of demand for grain. It will also use local labour forces in rural areas, thus avoiding further drift to China's already overcrowded cities, and will promote economic effectiveness by reducing the amount of transport needed.

It can be used to maintain the ecological balance of the environment and train a great number of people. It will heighten the material and spiritual civilization of Chinese people in rural areas, reducing the differences between two and the countryside.

On the basis of further diversifying economic activity, a great number of farm households which specialize in animal husbandry, forestry, small handicrafts, industry and transport have emerged. They are usually called "specialized families."

Some are contractors belonging to the collective economy compared with those who operate individually. Some join forces and operate within a group of several families. Although this new form of agricultural production is in an experimental stage, it has indicated the direction which will lead farm production to specialization and socialization.

These "specialized families" engage in commodity production and are quite different from self-supporting families of the past. As the members of "specialized families" are experienced in management and have production skills, so most of them achieve better economic results and are therefore better off than ordinary families.

It is natural for some peasants to become rich more rapidly than others through their labour and skills, and it is really a good thing to have richer peasant families under the socialist system--as long as they do not exploit others--because others can follow the same path.

In the course of economic development, many individual families will face common difficulties that will require joint efforts and cooperation in some phases of production. In that case, we can organize them well for production.

As is pointed out in a document from the 12th Party Congress, "it can be predicted that in the not too distant future, there will emerge in our rural areas an improved cooperative economy, with a diversity of forms, which will be able to capitalise on their advantages in the light of local conditions and facilitate the large scale adoption of advanced production measures."

By the end of this century, the lives of peasants in our country will reach a comparatively high standard, with their education and public health improved. Their consumption level of food and clothing and access to transport all also reach the world's medium level.

DEVELOPMENT OF WATER ENERGY RESOURCES URGED

Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese
No 3, 1982 p 25

[Article by Special Commentator: "Make the Most of Advantages, Hasten Development of the Country's Water Energy Resources"]

[Text] In the process of restructuring government organizations, the Water Conservancy and Hydroelectric Construction Company was formed. The company has been commissioned by the Ministry of Water Conservancy and Power to provide centralized leadership for national water conservancy and hydroelectric planning, surveying, designing, construction, and installation work, and for centralized management of manpower, financial, and material resources of subordinate units. This is a major result of the amalgamation of the Ministry of Water Conservancy and the Ministry of Electric Power, and it holds extremely important significance for the country's water conservancy and hydroelectric power construction.

China is a vast country with numerous rivers. Its water energy resources rank first in the world. It has theoretical reserves of 680 million kilowatts of which 370 million kilowatts may be developed for an electric power generating capacity of 1.9 billion kilowatt hours. Such an extremely abundant and valuable resource provides the country's water conservancy and hydroelectric power development endeavors with a vast field through which they may range. Our water conservancy and hydroelectric power construction corps possesses abundant technical strength, and it has accumulated rich construction experience. They are definitely skilled in their work. During the past more than 30 years they have built more than 20 million kilowatts of hydroelectric power stations, have excavated more than 500 million cubic meters of earth, have poured more than 50 million cubic meters of concrete, and have built a group of technically complex, remarkably beneficial large water conservancy and hydroelectric power projects such as the New Anjiang, the New Fengjiang, the Danjiangkou, the Liujiaxia, the Congzui, the Wujiangdu, the Bikou, the Fengtan, and the Gezhou dams. In 1981, hydropower generating output reached more than 65.5 billion kilowatt hours, an electric power equivalent to the burning of 40 million tons of coal. The broad masses of water conservancy and hydroelectric construction workers have struggled year in and year out in the deep mountains and gorges, arduously building and making a tremendous contribution to the country's water conservancy and hydropower construction endeavors.

At the present time, extent of development of our water energy sources is still comparatively low amounting to only 3 percent of reserves, and project construction periods are relatively long. Construction costs per kilowatt are also higher than formerly. There are objective reasons for the existence of these problems such as increases in the price of materials, increased engineering difficulties, increases in the expense of resettling people, etc. There are also subjective reasons such as many problems in work during the initial stages, construction management, in the building of a corps, and in organizational structure. Now with establishment of the Water Conservancy and Hydroelectric Construction Company, conflicts of an organizational kind in water conservancy and hydropower work have been solved. Duplication of organizations has been reduced, overlapping of work has been avoided, and in planning and construction, a change has been made from "separate efforts" to "joint efforts." This reform has benefited unified planning and overall control of rivers; it has permitted comprehensive consideration of flood prevention, power generation, irrigation, navigation, aquatic products, and supply of water for urban industry and daily life, full development of water resources for use, and rational economic planning of project construction. As a result of centralized management and centralized assignment of water conservancy and hydropower construction forces, in future the role of specialized technicians, of surveying, designing and construction units, and of machinery and equipment will be effectively brought into play, to create favorable conditions for hastening progress on projects, for improving project quality, and for all around increase in economic effectiveness of water conservancy and hydropower projects. This is a new strength that is building today in the country's water conservancy and hydroelectric power construction. Leaders, cadres, and workers as a whole at all levels on the front line of our water conservancy and hydroelectric power construction should rally their spirits, seize opportunities, make the most of strengths, focus on improvement in economic effectiveness, and hasten the pace of development to create a new situation in the building of the country's water conservancy and hydroelectric power.

Making the most of strengths and improving effectiveness entails, first of all, further strengthening of work during the early stage. The re-doing of work, work stoppages, and the seeking of more investment funds in the course of construction of some projects in the past resulted from failure to have done a good job during the early stage of work through being overly anxious to get started. In future it will be necessary to devote much attention to this work and do a good job of planning. Every project to be constructed will have to be studied and a good job done of designing and surveying the project, so that water conservancy and hydroelectric power construction will rest on a foundation of data that are dependable and make economic sense. Apart from satisfying current construction needs, project designs should be stored up to create conditions for future large scale development of hydroelectric power endeavors.

It is necessary to make sure to select priorities for development. In laying out construction tasks, it is necessary to give priority to development of water conservancy and hydroelectric projects where the need for electricity is urgent, conditions superior, investment economical, effectiveness great, and results quickly evident so that limited investment funds will bring maximum economic benefits. Low levels of administration and management, low labor productivity, and poor economic results are prominent problems in our water conservancy and hydroelectric power construction enterprises. An overall reorganization of enterprises centering on improved economic effectiveness should be done.

Leadership teams should be reorganized so that leaders of enterprises at all levels will be younger, better informed, specialized, and revolutionary for solution to the problems of laxity, weakness, overstaffing, and old age in teams. Economic responsibility systems will have to be established and perfected, and a construction organization management system that is scientific and cultured will have to be established. Cultural, technical, and vocational training will have to be given for all around improvement in the level of administration and management of enterprises.

Water conservancy and hydroelectric power construction is characterized by arduous environments and high labor intensivity. Many years' experience has shown that sole reliance on bonuses and reliance on money cannot make the construction teams good or project construction good. In addition to carrying out distributions according to labor, it is necessary that there be not the slightest bit of slackening of ideological and political work, vigorous development of campaigns to study the advanced and catch up with the advanced, to provide staff and workers with regular indoctrination in the proletariat being the masters of their own fate, and to give education in socialism, patriotism and situational education so that our construction corps will always maintain a vigorous fighting capacity, high revolutionary esprit, will unite to struggle, and work assiduously to make a greater constribution to water conservancy and hydroelectric power endeavors!

DEVELOPMENT OF RESERVOIR FISHING INDUSTRY URGED

Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 3, 82 p 28-30

[Article by Li Boning [2621 0131 1380]: "Raise the Reservoir Fishing Industry to a New Level As a Promoter for Development of the Freshwater Fishing Industry"]

[Text] Since founding of the Chinese People's Republic, very great development of water conservancy construction has taken place. During the period immediately following Liberation, there were only 15 reservoirs in the entire country, but today there are more than 86,000. They have not only been effective in flood prevention, irrigation, power generation, in providing water, and in shipping, but they have also provided spacious water surfaces and conditions for development of the freshwater fishing industry. Reservoirs in the country in which fish may be raised have a water surface of 30 million mu, which is about 40 percent of the freshwater in the country in which fish may be raised. With steady future development of reservoir construction, the economic significance and tremendous potential of the reservoir fishing industry will certainly be increasingly manifest.

Since the Third Plenary Session of the 11th Party Central Committee, the Central Committee has formulated a series of programs and policies for development of the rural economy, and the State Council has promulgated "Regulations on the Breeding and Protection of Aquatic Product Resources," and "General Order on Protecting the Security of Reservoirs and of Aquatic Product Resources." It has approved and sent forward the "Report on the Raising of Fish in Reservoirs and Development of All Around Operations" from the Ministry of Water Conservancy, the Ministry of Finance, and the National Aquatic Products Bureau. Last year the CCP Central Committee and the State Council forwarded the State Agricultural Commission "Report on Active Development of Rural Economic Diversification," which has powerfully promoted development of the reservoir fishing industry. Quite a few provinces, prefectures, and counties have conscientiously made arrangements for special funds for reservoir fisheries handed down by the state, have increased disbursements of funds for support of water conservancy construction project development of economic diversification and the reservoir fishing industry, and have organized reservoir fishery technical training for several thousand attendees annually. New techniques for hatching, catching and preventing the escape of fish have been promoted with benefit in many places. Many reservoir fish farms have instituted independent accounting, have adopted quota management, have linked calculation of remuneration to output, and have instituted production responsibility systems of various kinds for specialized contracting, and for hatching, raising, catching, and marketing in one continuous integrated process, which has stirred the enthusiasm of staff and workers. Today reservoirs under the administration and management of water conservancy departments have a fish raising water surface of more than 16 million mu. Thanks to the serious attention given by leaders at all levels, the cooperation of water conservancy and aquatic products departments, and efforts by reservoir fishing industry staff and workers, reservoir fishing industry output has steadily increased year after year. During the past 3 years, many places have experienced serious floods and drought, yet adult fish catches in the nation's reservoirs has continued to rise steadily year after year, reaching 120,000 tons in 1981 for an almost 30 percent growth over a period of 3 years. The extent to which reservoir management units and fish farms have been able to provide for their own expenses has improved remarkably. Substantial progress has been made in reservoir fishery techniques using the natural drop of impounded water to carry out high density raising of fish in running water, in use of net cages for overwintering and the raising of fish varieties of high quality, in the relocation and domestication of new varieties, as well as in making catches and preventing escapes.

Formerly water conservancy departments have lacked confidence about reservoir fisheries. First, they were worried about too little experience; second about a lack of qualified personnel; third about being saddled with losses; and fourth they felt they would lose control as a result of taking up the fishing industry. After 3 years of experience their mental concerns have gradually dissipated and their confidence and determination about the reservoir fisheries have been strengthened. The facts tell us that in operating reservoir fisheries, water conservancy departments will benefit from full use of water and soil resources, will benefit from centralized project management that makes the most of all around effectiveness, and will benefit from management unit self-sufficiency in operating funds, and in expansion of reproduction to create wealth for the country.

Nevertheless, many problems still exist in the reservoir fishing industry. One is that water surfaces utilization rates and yields per unit of area are too low. No one is raising fish on almost 9 million mu of reservoirs administered by water conservancy departments, and where fish are being raised, yields average only a little more than 10 jin per unit of area. Secondly, in the reservoir fishing industry, capital construction including hatching, raising, catching, and prevention of escape are not integrated. There are great shortages of funds, organizations and systems are not well developed, material and feed channels needed by the fishing industry are blocked; there is a shortage of people qualified in aquatic products, and scientific raising of fish still awaits general upgrading. Third, fishing industry production is chaotic with poaching of fish, dynamiting of fish, theft of fish, and poisoning of fish frequently occurring. Not only does this destroy aquatic product resources, it also endangers the safety of reservoirs. We have to summarize experiences conscientiously, look for gaps, formulate measures, and go farther in the raising of fish in reservoirs. This March the National Freshwater Fishing Industry Work Conference, convened by the National Agricultural Commission, called upon the reservoir fishing industry to bring about tremendous growth during the 1980's, asking that they strive for an output totaling between 400,000 and 500,000 tons. This is a glorious task.

We imagine that during the 1980's the almost 15 million mu of large reservoirs in the country will be fully used, and that average yields per unit of area will rise from the present 7-8 jin to 15-20 jin. Water surfaces on the approximately 15 million mu of medium and small size reservoirs that can be used will see average yields increase from the present 25 jin to between 40 and 50 jin. Total output of the reservoir fishing industry will rise from the present 120,000 tons to between 400,000 and 500,000 tons. During the past 3 years, the reservoir fishing industry in quite a number of provinces (or regions) has grown substantially. In Hubei Province, that land of fish and rice, it has grown 46 percent, in Sichuan, it has grown 70 percent; it has doubled in Jiangsu; and both Jiangxi and Guizhou have seen a more than twofold increase. We believe there are many factors favoring development of the reservoir fisheries, that there are large amounts of water surfaces capable of raising fish that remain unused, that the present production starting point is low; that conditions are good for raising high quality fish varieties, and that large quantities of fish food exist within reservoirs and bodies of water. What these areas have accomplished, other areas are also entirely capable of accomplishing, and are capable of surpassing.

Small reservoir fisheries require little investment and results may be seen quickly. Small pond-like reservoirs lend themselves particularly to development of "intensive raising," and within a short period of time, yields can increase by several tens of jin up to 100 jin per mu. While continuing to devote attention to large and medium reservoir commodity fish bases, water conservancy departments should make small reservoirs one of their major targets for attack. They should give strict attention to making overall plans taking all factors into account for both irrigation and the raising of fish for all around utilization.

For future accelerated development of the reservoir fisheries, the following views are offered:

(1) Understanding of the importance of reservoir fisheries must be increased. Reservoir fisheries are a major aspect of the overall benefits derived from reservoirs, and also a major ingredient in management unit development of overall operations. It is hoped that party and government leaders at all levels will be able to make reservoir fisheries a part of planning, organization and implementation of local development of large scale agriculture. All levels of water conservancy and hydroelectric departments should devote attention to reservoirs as a major matter in overall utilization of water resources for the realization of increased output and increased earnings, to create prosperity for the people, to improve the livelihood of staff and workers, and to advance management.

The principle of "management by and benefits for the builder" should be adhered to, with perfection of management systems, defining the scope of management. In accordance with the principle of echelon by echelon management, plans for development of fisheries and annual plans should be drawn for each reservoir. There should be a determination to improve existing reservoir fishery facilities by stages and in groups. During the "65" period, throughout the country the fishing equipment needed by the more than 300 large and medium size reservoir commodity fish bases that have been already constructed or are under construction should be further developed and completed. While removing dangers and strengthening reservoirs, all jurisdictions should look after the need for reservoir fisheries, building them at the same time and inspecting them for acceptance. In future building of reservoirs, from design to construction and from management and use, consideration is to be given at the same time to facilities needed for a reservoir fishing industry and multiple uses, both being examined and approved at the same time. We walked a tortuous road in the past, and we should summarize the lessons of this experience very well.

(2) Active development of multiple operations, strengthening of economic accounting, and steady improvement in levels of self-sufficiency in expenses. Today, state-owned water conservancy project management units above the county level number nearly 10,000, and during the past 3 years units that have used water and soil resources within the scope of their management, and have adapted general methods to local situations for the launching of economic diversification and active collection of fees for water and electricity to achieve virtual self-sufficiency or some surplus in meeting expenses number 45 percent of this number. This includes a 55 percent self-sufficiency rate for water conservancy projects. In 16 counties, municipalities, or autonomous regions in the country, state-owned water conservancy project management expenses and total earnings are virtually balanced, or earnings are greater than expenditures. Inasmuch as most water conservancy project management units are entrepreneural units that earn their own income and pay their own expenses and for which there is no mutual adjustment of profits and losses between one unit and another or one prefecture or county and another, annually the state has to provide a 100 to 200 million yuan subsidy from water conservancy enterprise funds or from funds that localities have contributed themselves. At the present time, more than half of management expenses for state-owned water conservancy projects derive from state support. The way to change this state of affairs is to increase income and reduce expenses. Water conservancy project management units have superior conditions for development of planting industries and breeding industries. In palces in which reservoirs are situated at the foot of a hill and beside a stream, in particular, the raising of fish and afforestation should be the major emphasis of multiple operations. Right now all jurisdictions in the country are carrying out a campaign of obligatory tree planting by all the people, and our water conservancy and hydropower departments, particularly the water conservancy project management units, should stand in the forefront of this campaign, persevere in it, carrying on without let up for many years to do a good job of afforestation and beautifying the environment. Future inspection, evaluation and comparison of reservoir administration and management should have as its major ingredient the raising of fish and afforestation.

Water conservancy projects have numerous facets; operations are of many kinds; their product batches are small; the production cycle is long; and the rate of profits is fairly small. Unified planning must be done through adaptation of general methods to local situations for planned development of key areas in order to produce batch lot production as rapidly as possible to achieve economic benefits. For a long time supply channels for feed and materials needed in the fishing industry and that are related to reservoir fisheries have not functioned smoothly. After the National Freshwater Fishing Industry Work Conference made regulations to meet the problem, this kind of problem will henceforth be included with freshwater fishing industry channels and will be properly solved equally and without discrimination. In order to link production, supply and marketing channels, it seems that organization and establishment of various kinds of multiple operations companies is a necessity. Today, Nei Monggol, Jiangsu, Zhejiang, Jilin, and Beijing, as well as quite a few prefectures and counties have organized establishment of water conservancy project multiple operations companies, which have been very effective in promoting development of multiple operations. It is suggested that all provincial (municipal and regional) water conservancy departments (or bureaus) take action, in conjunction with system reform, to organize and establish multiple operations companies at all levels as soon as possible. At the same time it is hoped that all jurisdictions will give needed financial support to reservoir fisheries and to development of multiple operating endeavors so as to promote development of these endeavors with all possible speed.

(3) Take a firm grip on technical training and give attention to scientific raising of fish for consistently high yields from reservoir fisheries. At the moment, effective scientific techniques should be promoted; attacks on key problems should be organized; and personnel should be energetically trained. Water conservancy departments in all provinces (municipalities and regions) should be asked to send graduates of water conservancy institutions to enhance technical forces. Water conservancy departments at all levels should cooperate closely with aquatic product departments in the running of short specialized technical training classes, group after group and over a period of time. Special funds pertaining to scientific research and training should be provided in accordance with requirements of the 1979 notice from the former Ministry of Water Conservancy.

(4) Strengthening of fishery management and improvement in relations between reservoirs and the masses. During the past few years Yantai Prefecture in Shandong Province has taken action to help communes and brigades in reservoir areas to develop production and improve living conditions with very good results. The Prefecture CCP Committee has organized all units concerned to support reservoir area communes and brigades in expanding their cultivated land, in building water conservancy, in constructing roads and building bridges, in adapting general methods to local situations for development of economic diversification, and in arousing irrigation areas to support the building of production in reservoir areas, in readjusting reservoir area grain and oil state procurement quotas, in reducing or not collecting fees for water, and in lightening labor burdens to bring about great changes in reservoir areas. This has both improved relations between reservoirs and the

masses, and has also pretty well solved order problems in the fishing industry. Other provinces (municipalities and regions) have had similar experiences that are worth conscientious promotion. In addition, education in the protection of reservoirs and love for reservoirs, and respect for laws should be widely spread among grassroots level cadres and the masses. Reservoir teams should be organized for joint prevention and joint care for the common protection of reservoir safety to obtain benefits from projects. Large reservoirs and key medium size reservoirs having a great bearing on the national economy and the livelihood of the people should, following discussion with and agreement from departments concerned, establish public security outposts or economic police, personnel and expenses being the responsibility of water conservancy departments, public security departments conducting investigations, training, and providing equipment. For the small number of lawless elements who refuse to change despite repeated education, who destroy projects and aquatic product resources, and who beat custodial personnel, discipline must be meted out in accordance with the law. Major cases that have not yet been disposed of should be solemnly handled quickly.

In recent years many places have been organizing pilot projects in association with or jointly with reservoir fishery communes (or brigades) concerned. This new born creature should arouse the serious attention of leaders at all levels. Practice everywhere has shown that among state-owned reservoirs, those commodity fish bases that have already achieved consistently high yields and have achieved batch production should not lightly change their fishery organization. Reservoirs that straddle administrative zones of water surfaces not readily managed that have low yields, should adhere to the principle of "three no changes" (namely, no change in centralized management leadership authority for reservoirs, state ownership of water surfaces, and ownership by all parties to associated operations; no change in reservoir and commune and brigade voluntary participation for mutual benefit; and no change in joint investment and joint responsibility for profits and losses), and may, under the centralized organization of reservoir management units, selectively operate joint or associated pilot projects. Specific forms of organization and provisions may be adapted from general practices to specific reservoirs. In raising, catching, intercepting, or protecting, either individual or multiple joint operations or associated operations may be used with step-by-step summarization of experiences to effect improvements. It is necessary to run pilot projects, first of all, with no rash action being taken or no "arbitrary uniformity" practiced. In the protection of bodies of water and the development of aquatic product resources, everyone bears responsibility. Water conservancy and hydropower departments are even more duty bound, and they should be promoters of the development of the freshwater fishing industry. Following diligent summarization of the lessons of experience, the Ministry of Water Conservancy and Power has emphasized in pertinent documents and professional conferences the issue of "saving trees, saving boats, and saving fish," and has drafted corresponding regulations. This was reiterated at the 1979 national conference on exchanges of experiences and the raising of fish in reservoirs and in multiple operations, and at last year's national water conservancy management conference. Now, water conservancy departments everywhere are in process of a comprehensive "three inspections and three stipulations," and water conservancy facilities that genuinely impede the "three saves" will be studied one after another, necessary remedial measures taken.

For many years water conservancy departments and aquatic products scientific research organizations and institutions at all levels have been very greatly concerned about water conservancy endeavors, and they have given extremely great support to reservoir fisheries. In the development of freshwater fisheries, water conservancy and aquatic products have a common goal and a common mission. Let us unite further and jointly make new contributions in the promotion of consistently high yields from the freshwater fishing industry.

BRIEFS

STATE FORESTRY FARMS--Since 1979, state forestry farms in China have produced an average of 4 million cubic meters of lumber each year, 70 million jin grain, 14 million jin fruit, 1.9 million jin tea and 700,000 jin medicinal herbs. [OW231311 Beijing Domestic Service in Mandarin 0400 GMT 8 Sep 82]

EDIBLE OIL RATION--The Ministry of Commerce and Ministry of Finance have instructed various areas to provide an additional ration of two jin of vegetable oil per head for non-agricultural people throughout the country in observation of National Day. This is the largest amount additionally provided for a festive occasion since the introduction of the planned purchase and marketing of edible oil. This shows that since the third plenary session of the 11th CPC Central Committee, the situation concerning edible oil has become increasingly favorable from year to year. AGRICULTURAL MEETING--The Anhui Provincial CPC Committee sponsored a meeting in Guzhen County from 21 to 24 August to discuss matters concerning autumn planting. Wang Guangyu, secretary of the provincial party committee, and Meng Fulin, vice provincial governor, were present at the meeting, which was attended by 135 comrades in charge of agriculture in Hefei and other localities. It was reported at the meeting that output of the summer harvested crops in Anhui has exceeded 10 billion jin this year, mainly due to the implementation of the system of responsibility for agricultural production, improvement of soil fertility and the irrigation system. The meeting urged all areas to focus attention on wheat production this fall and fulfill various production quotas to insure greater wheat output next year. RURAL COMMUNE'S WORK SYSTEM ACHIEVEMENTS NOTED

HK020606 Beijing CHINA DAILY in English 2 Oct 82 National Day Supplement p 5

[Article by Hu Wenshun, secretary of the Shuangqiao People's Commune Communist Party Committee]

[Text] Shuangqiao People's Commune in the Chaoyang District is one of Beijing's rural communes. It has 12,846 households who make up 47,719 people, and 52,000 mu (3,466 hectares) of farm land. There are 14,000 laborers and 7,000 factory and sideline workers. It is composed of five rural management areas with 62 production brigades.

The commune's chief concern is agriculture but at the same time, it is trying to develop in many fields. It has set up offices or stations in charge of industry and sideline activities, animals and fishery, hydropower, science and technology. There is also a hospital and a school for workers.

Great changes have taken place since the third plenary session of the Communist Party's Central Committee in December 1978. The establishment of various kinds of responsibility system was what the people wanted.

In only 3 years, major economic gains have set historic records. Agricultural and industrial gross income in 1981 amounted to 72.94 million yuan, an increase of 78 percent over the 40.94 million yuan in 1978. Average annual distribution per capita was 370 yuan, increased by 90.7 percent (194 yuan in 1978).

For 3 years running, Shuangqiao's farming, tree planting, animal raising, fishery and sideline production have all expanded, while crop yield has stabilized above 35 million jin (17.5 million kilograms).

The year 1981 was the sixth that its per mu yield reached over one thousand jin (7,500 kilograms of grain from one hectare). The per unit area yield of 33,000 mu (2,200 hectares) of grain field was 1,067 jin (533.5 kilograms). Vetetable output has been 52 million jin (26 million kilograms) every year. Milk cows increased by 50 percent from 12,000 3 years ago to 18,000 now. Milk production was increased by 35.6 percent and pigs increased by 41.6 percent. The fish catch has doubled. Chicken farms, force-fed duck farms and orchards were expanded.

About 100 industry and sideline enterprises have been developed, run either by the commune, or by brigades. Gross income from these enterprises grew from 30 million yuan in 1978 to 50.13 million yuan, in 1981, an increase of 67 percent.

The commune has helped enrich Beijing's market by selling more produce to the state. Its commodity grain increased by 71.6 percent. It also provides the market every year with 45 million jin (22.5 million kilograms) of vegetables, 11.2 million jin (5.6 million kilograms) of fresh milk, 17,000 pigs, 230,000 jin (115,000 kilograms) of fresh fish, 500,000 jin (250,000 kilograms) of eggs, 60,000 ducks and 3.6 million jin (1.8 million kilograms) of fruits.

The increases are attributed to the responsibility system. The Wuliqiao brigade is an example. It contracted 54 mu of land (less than 4 hectares) to 28 commune members for specialized production. The total output was 62 percent higher than the previous year and the members' income quadrupled. The average value of production per mu (1/15 of a hectare) rose to 1,144 yuan. The average annual distribution to each laborer was 1,370 yuan with the highest more than 1,800 yuan.

In the last 2 years the living standard of the commune members has been improved. According to a survey, some 1,900 households have built 6,000 new houses. Fifty percent of the households have bought TV sets. Thirty percent of the brigades have set up pensions for elderly members over the age of 60, ensuring the livelihood of the commune members when they lose their ability to work.

Shuangqiao People's Commune is looking forward to an even brighter future in 1983.

HEBEI, HENAN WATER CONSERVANCY PROJECTS ASSESSED, FOUND WANTING

Beijing CAIZHENG [FINANCE] in Chinese Nos 7 & 8, 5 Jul, 5 Aug 82

[No 7, 5 Jul 82 pp 1-3]

[Article by Survey Unit, Ministry of Finance: "Survey Report on Questions of Investment Benefits From Water Conservancy Construction in Hebei and Henan"]

[Text] Editor's Note: During the last half of last year, on instructions from Central Committee leadership comrades, the Ministry of Finance sent a survey team headed by Comrade Jiang Dongping [3068 2639 1627] to 14 counties in Hebei and Henan provinces to conduct a more than 3 month long survey of economic benefits derived from investments in water conservancy there. The survey team held informal discussions with local leadership comrades at all levels and with comrades in finance and water conservancy departments. They listened to the views of some water conservancy specialists, asked questions of commune and production brigade grassroots cadres and commune members, inspected some water conservancy projects and the transformation of water sources, and wrote a survey report. Central Committee leadership comrades made some important written comments on the survey report and instructed departments concerned to study the report seriously and to provide a water conservancy program for North China and major actions to be taken. This survey report will be published in two separate issues of this journal.

The new circumstances and new problems public financial work now faces are very numerous and require that we vigorously intensify our investigation and study work. It is hoped that government financial departments everywhere will be able to identify some topics and organize forces to carry out an investigation and study of them, and it is hoped that they will also select some survey reports for mailing to us so they may be published in this journal for an exchange.

Water conservancy construction achievements in the two provinces of Hebei and Henan have been very great. In the 30 years between 1951 and 1980 payments for water conservancy construction in these two provinces amounted to about 45 percent of payments made for support of agriculture. The two provinces used this investment to do many things. As compared with the period immediately following Liberation, the irrigated farmland area in Hebei Province increased from 11 million mu to 54 million mu; in Henan, it increased from 6.35 million mu to 58 million mu. Following the testing that the last several years of drought have provided, the area of each of the two provinces that can be fairly well assured of irrigation has been shown to be about 30 million mu. Expansion of the irrigated area has given powerful impetus to development of agricultural production. Some water conservancy projects have played a very good role as well in the prevention of floods, elimination of waterlogging, and reducing soil alkalinity as well as providing cities water for use. However, as a result of this survey we also feel that considering the tremendous cost to the country and the people, benefits from investment in water conservancy construction in these two provinces have not been all that they should have been. This is particularly true of some projects from which anticipated benefits were not derived following their construction. In order to conscientiously summarize the lessons of experience so that water conservancy construction will "genuinely proceed from realities," every available means used to increase economic benefits," and so that "the people will derive greater material benefits" from them, several problems deserve careful study for gradual solution.

1. The Question of Benefits From Reservoir Construction

Investment in the building of reservoirs constituted a very large proportion of water conservancy construction in the two provinces amounting to about 40 percent of total water conservancy expenditures. Total design capacity of reservoirs already constructed was for 9.5 billion cubic meters in Hebei Province and 13.3 billion cubic meters in Henan Province, and they were definitely effective in flood prevention and irrigation. However, for many reservoirs, economic benefits were not sufficient. Their actual water storage capacity was vastly lower than design capacity to the detriment of their effectiveness in irrigation and flood prevention. Among the several reservoirs that the survey team visited, except for individual reservoirs in which the water storage situation was fairly good, in most the actual current storage capacity is only about 10 percent of design storage capacity.

Why is it that actual reservoir storage capacity is vastly lower than design storage capacity? Aside from the protracted drought in North China during the past several years, one major reason is the poor quality of engineering. Faulty and dangerous reservoirs are numerous and they are thus unable to meet designed standards for impounding water and for holding back flood waters. For example, a reservoir in Lin County, Henan Province was started in 1958 and completed in 1960. It had a design storage capacity of 66.9 million cubic meters for a planned irrigation area of 100,000 mu. After it was completed, the dam leaked seriously and water could not be impounded in it. For 20 years it has been fixed year after year at a total investment of 70 million yuan (including a national investment of 20.93 million yuan), and today it is still a faulty reservoir that cannot impound water. According to a briefing provided by water conservancy departments in Henan, 10 of the province's 19 large and medium size reservoirs are faulty or dangerous, and 540 million yuan has already been invested in these reservoirs. Another 500 million yuan will have to be spent strengthen them and eliminate danger. In August 1975 following the collapse of a dam in Henan Province, water conservancy departments proposed the principle for water conservancy projects of "designed for 1,000 years, and checked for 10,000," with existing reservoirs being reinspected using the rains of "August 1975" as the criterion. As a result, some reservoirs of fairly good quality were put on the list of faulty and dangerous reservoirs in a situation in which every reservoir posed some danger. As a result of erosion and the serious silting of reservoirs as well, for many reservoirs urgent action had to be taken for "emptying reservoirs in advance of the flood season and releasing flood waters without impounding them." Before the advent of the flood season, water was flushed from the reservoirs and they were cleaned out, and during the flood season they dared not be used either to hold back flood waters or for storage. After the flood season had passed, there was no water to be stored; consequently, their effective usefulness was impaired.

Another major reason is that too many large scale projects were started. As a result, large numbers of projects were never completed or were not fully equipped. Hebei Province has reported a total of 133 half finished reservoir or irrigation ditch projects throughout the province (not including add-on projects started by prefectures and counties). After eliminating 22 of these that were duplicatory and to be "dismantled," an investment of 870 million yuan would still be required to finish construction of the others. For half finished water conservancy projects in Henan Province, an additional investment of 2 billion yuan would be required to complete construction. At the two province's current levels of investment, even if all new projects were to be halted, it would still take from 20 to 40 years to complete these leftover projects. Despite the very many problems with leftover water conservancy construction, some places have not learned the lesson. Seeing the good current rural situation, they want to continue overbuilding. After rural production responsibility systems were set up last year, in one county in Henan Province communes and brigades grew more tobacco to increase production and increase earnings. County public revenues also experienced a surplus, so it was decided to build six more reservoirs. The county arranged for Chengguan Commune to build one reservoir, and the commune did not wait until the fall harvest was in to begin construction of three additional reservoirs assigning responsibility for work on them to households on the basis of the average number of people in them. For households having few working members, harvesting of the peanut and sweet potato crops had to be left unfinished, and during fall and winter the soil could not be turned over nor manure collected. Embankments along fields could not be given any repairs, and there was fear that during the following year households might not be able to fulfill their fixed output quotas.

On the basis of the situation in the two provinces of Hebei and Henan, many problems requiring serious study exist in future water conservancy construction. Since Liberation, the state, communes, brigades, and peasants have invested large amounts of manpower, material, and financial resources in the building of reservoirs and large irrigation ditches. It has been estimated that for every yuan of state investment, the masses have to add two. In virtually every place where a reservoir should be built, one has been built, so henceforth aside from the reservoirs necessary to assure the water needs of urban industrial production and of the daily life of residents, no further large or medium size reservoirs should be built. The focus of efforts should be shifted to making the most use of and improving benefits derived from existing reservoirs. In addition, existing reservoirs should be classified in order of priority. Where reservoir quality and water resources are fairly good, these should be genuine strengthening of safeguarding and management to make full use of their effectiveness for irrigation and flood prevention. Some of these will require more construction and equipping, and arrangements should be made for this in a planned, step-by-step way insofar as financial and material resources permit. When reservoir quality is fairly good but water sources inadequate, the originally designed irrigation area will have to be revised, and the volume of water actually available taken into consideration in equipping them. Where reservoir quality is poor and water sources fairly good, the reservoir should be made safe, first of all, and in the strengthening and elimination of danger in faulty and dangerous reservoirs, specific requirements that are realistic will also have to be worked out. When water sources are insufficient, and reservoir engineering quality is poor as well, and there is no way to effect fundamental improvements, further construction and equipping should be halted or the reservoir should be scrapped. While guaranteeing the safety of places downstream, proper handling of the existing project should be done. In order to protect and make the most of the effectiveness of existing reservoir projects and facilities, firm grip has to be taken on soil and water conservation work in the areas of rain concentration in the upper reaches and in the reservoir area. When building new reservoirs, provisions for commensurate soil and water conservation projects should also be made part of plans. Continued future mobilization of the masses to build some small reservoirs that hold genuine benefits for the promotion of production is necessary, but the principle of voluntary participation by the masses is to be adhered to, construction tasks assigned on the basis of the size of benefits to be gained. When communes and brigades that will not benefit help with construction, they should be paid fair compensation.

2. Problems in Doing a Good Job of Water and Soil Conservation

For a long time great attention has been given to engineering measures for water control while the planting of trees, the growing of grass and such biological measures to preserve the ecological balance of the land have been neglected. Action has not been taken to get at the root causes of floods, and this has been a mistake. Water conservation funds from these two provinces used for water and soil conservation amounted to 0.6 percent of the total investment in water conservancy for the same period, and most of this money was also used in engineering measures to conserve soil and water, with very little used on biological measures.

On the one hand the planting of trees and the growing of grass for water and soil conservation and to hold water has been neglected, while natural forests and ground cover have been destroyed on the other, many grave consequences resulting. Destruction of the original forests in the mountain regions of these two provinces has been serious as a result of the large scale steel making efforts of 1958 and the cutting off of "vestiges of capitalism" in 1970, large scale felling of timber having been done both times, including the use of timber forests and economic forests (such as persimmon trees, walnut trees, Sichuan pepper trees, and apricot trees). For example, somewhat more than 160 households in Zhangjiazhuang, Paihui Commune, Wuan County in Hebei Province formerly had an average of somewhat more than 100 persimmon and walnut trees per household, and the masses there had a saying that, "persimmons and walnuts are like a crop of grain." Today only somewhat more than 700 trees remain in the entire village. Formerly the masses in mountain regions lived off the mountains where they lived, but after several major timber cuttings, the livelihood of the masses is hard, and they have no choice but to live off of the relief provided by the state.

As a result of the destruction of the ground cover, which make it impossible for the soil to hold water, plus drought, some of the streams in these two provinces have become waters without a source. In Hebei Province many of the more than 600 streams have stopped flowing. Some streams have been cut off inch by inch, seriously impairing irrigation and navigation. In Henan Province, navigable waterways have declined from 3,839 kilometers to somewhat more than 800 kilometers. Between Taihang Mountain and Chong Mountain, everywhere there are barren hills and mountains, soil erosion, and serious silting of reservoirs. In 1963, after holding back flood waters just once, silting of the Yuecheng Reservoir ran to 50 million cubic meters. In Luoyang Prefecture after about 10 years, 16 reservoirs have become entirely filled with silt and abandoned.

In order to improve China's natural climatic conditions and do a good job of further water conservancy construction, it is necessary to begin right now to treat vigorous intensification of water and soil conservation work as a strategic task that bears on the fundamental welfare of future generations of the Chinese race. In building water conservation, it is necessary to closely combine both engineering measures and biological measures. Distribution of funds for water conservancy must also be correspondingly readjusted on the basis of the foregoing. In view of the present state of soil erosion and the need for control by stages, in future the proportion of water conservancy must also be correspondingly readjusted on the basis of the foregoing. In view of the present state of soil erosion and the need for control by stages, in future the proportion of water conservancy expended will have to be increased for soil conservation.

The problem of a future source of funds for conservation of soil and water may be solved by cutting back on or readjusting water conservancy construction projects, and will not necessarily require increases in new expenditures of public funds. For example, in order to prevent flood waters from flowing into the Huang He, Henan Province is in process of building a reservoir with a design capacity of 1.2 billion cubic meters on the Luo He. Since the beginning of construction of this reservoir in 1958, it has gone through several ups and downs and more than 30 million yuan has been spent. If work continues, units concerned figure that an investment of about 1 billion yuan will be required (including an associated irrigation ditch system). Reportedly the geology for this reservoir is uncertain and there is serious fracturing of the bedrock for the dam. Even if completed, it might not meet standards because of safety and would not dare be used to hold back or store flood waters. It also might become silted as a result of serious erosion upstream. Some comrades have noted that expenditures of these funds on soil and water conservation in the mid and upper reaches of the Huang He and in the Luo He region would be more beneficial. They have figured that were these funds used to subsidize communes and brigades, 100 million mu could be afforested. If used as investment in a state-owned forest farm, 25 million mu could be afforested. Figuring 20 cubic meters per mu of water retained by a canopy forest, the economic benefit derived from this measure alone would be the equivalent of that derived from a more than 500 million cubic meter green reservoir that would long endure and from which waters would long flow. Some experts have suggested that the state annually allocate special investment to undertake comprehensive control of the middle and upper reaches of the Huang He, starting with the 100,000 square kilometer area where erosion is most serious in the gorges in Shaanxi and Shaanxi and in the basins of the Jing and the Wei, so that after between 10 and 20 years of unremitting efforts the amount of silt entering the Huang He will be reduced by 50 percent, and the coarse sand that causes most damage reduced by 60 percent. This is a program that goes to the root of the problem that merits serious attention. A good job of water and soil conservation will require the concerted efforts of water conservancy, forestry, agriculture, and planning commission departments, as well as all the provinces concerned making cooperative efforts and working in common. This is the only way in which to derive greater effectiveness, and it is suggested that the state designate a department possessed of authority the responsibility for carrying out this task.

[No 8, 5 Aug 82 pp 1-3]

[Text] 3. Problems in Developing Pump Well Irrigation and Overcoming Excessive Extraction of Ground Water

Through the ages the two provinces of Hebei and Henan have had a tradition of using well water to irrigate the land. Today Hebei has 560,000 pump wells, and Henan has 500,000, which are outstandingly successful in developing irrigation and promoting production. Over the years Hebei Province has subsidized the sinking of wells with an investment of 730 million yuan to develop an irrigation area of 40 million mu, which is 74 percent of the irrigated area. Over the years Henan Province has subsidized the sinking of wells with an investment of 487 million yuan for development of an irrigation area of 34 million mu, which is 58.6 percent of the irrigated area. "With wells all is green; without wells all is brown." Well irrigation has truly caused agricultural production to go up in many places. As a result, enthusiasm for sinking wells is very high in these places.

A current problem deserving of attention is that wells are being sunk in ever increasing numbers to ever increasing depths, and the water table is sinking dramatically occasioning a series of problems. In Hebei Province the conflicts are extremely prominent. Measurements recorded at Xinhe, Wei, and Nangong counties show a general 20 to 30 meter decline in the water table in deep strata during the past 10 years. In Hengshui and Cangzhou prefectures, the water table has dropped an average 3 to 5 meters annually in places of high deep well density. Seven funnel areas have occurred in the province affecting 47 counties and municipalities over an area of 7,000 square kilometers. In Henan Province, the water resources are somewhat better than in Hebei; however, there too water tables are steadily on the decline, and 16 funnel areas have occurred over an area of 2,200 square kilometers. Analysis of measurements shows natural replenishment of deep strata ground water to be extremely difficult, every little bit pumped out means a little bit less. At Cangzhou, Hengshui, Tianjin, and Handan partial soil subsidence has occurred as a result of the lowering of the water table, and future trouble is a worrisome possibility. The suddenness of the drop in the water table has forced the frequent changing of pumps and constant removal of pump wells from service for very great losses to the country and to communes and brigades. Reports from Nangong County tell of the replacement of five different generations of pumps in less than 10 years. Changes have gone from centrifugal pumps to simple deep well pumps, to deep well pumps, to phreatic water pumps, to JD-type industrial deep well pumps. The height water has to be raised has gone from about 10 meters to 40 meters, or as high as 60 meters. Cost of raising a ton of water has increased from 0.0054 yuan to 0.021 yuan, a threefold increase. Statistics show the abandonment of 228,000 pump wells in Hebei Province between 1973 and 1978, 61,569 of them in 1978. In Xinhe County, between 1970 and 1980 a total of 1,730 wells were sunk, and during the same 10 year period 1,128 were abandoned.

Leadership comrades in some prefectures have pointed out the need for strict future control over the extraction of water from deep strata and full use of water in shallow strata, using water in deep strata for strategic conservancy, and permitting public funds subsidies intended for investment in deep wells to be used to subsidize shallow wells or other small water conservancy facilities. This is a sensible idea. Replenishment of water in shallow strata through precipitation is easy, and such wells can be continuously used, are easy to tap, and require small expenditures. Following institution in rural villages of production responsibility systems, in some places a single household or a combination of several households of commune members put to use old abandoned dug wells or bricked wells. They used manpower, animal power or small pumps to lift water, or sometimes they used hand operated pumps (that the masses call "old man happy" [pitcher pump] to raise water with very good results for watering the fields to combat drought. In a situation of surplus rural manpower, full use of manpower, using water in shallow strata to the greatest possible extent, saving energy for the country, saving expenses for commune members, and increasing income should be encouraged and supported.

In most parts of North China the amount of water required to grow 400 jin per mu of wheat or 100 jin per mu of cotton is about 400 cubic meters. It has been calculated that in Hebei Province, under normal weather conditions, water resources amount to an average of only 188 cubic meters per mu of cultivated land so for every person in the province to water a mu of land is, in fact, impossible to achieve. Any forced efforts to achieve it would inevitably lead to overtapping of ground water causing disastrous consequences. In addition to drought, changes in the growing of crops have also artificially increased the shortage between supply and demand of water. Under the guidance of the former mentality of "reversing the transfer to the north of grain from the south," the area sown to wheat in Hebei Province rose from 27 million mu during the 1950's to 42 million mu in the 1970's, and cotton declined from 15 million mu to 8.2 million mu. The growing season for wheat takes place almost entirely during the dry season and it is dependent on irrigation for two-thirds of its water needs. The growing season for cotton occurs during the rainy season, and rainfall substantially satisfies its needs. Drought tolerant millet and gaoliang cultivation declined from 46 million to 14 million mu, and corn, which takes a lot of water, increased from 20 million mu to 35 million mu. In a situation in which water resources could not be assured, large scale development of water loving crops meant inconsistent harvests. In 1979, wheat output in Hebei Province amounted to 12.68 billion jin, but in the 1980 drought year they plummeted to 7.98 billion jin, yields falling from 298 to 185 jin per mu. The ratio of water loving to drought tolerant crops should be decided on the basis of the possibility of tapping water resources for use. Places having fairly good water resources should actively develop irrigation; however, areas in which water resource conditions are arid or semi-arid should not push for a large irrigated area; instead, they should give greater attention to development of drought tolerant crop agriculture. In order to ameliorate the ever sharpening conflict between water resources supply and demand, both Hebei and Henan should study suitable readjustments of their crop growing structure. Mountain regions should also encourage the building of "three conservation fields," and study the spread of drought tolerant high yield crop varieties.

The year after year drought in Hebei Province and Tianjin Municipality has meant a shortage of water for the cities and countryside, making necessary the diversion of the Huang He over great distances. While Hebei is experiencing a water shortage on the one hand, it is making a "fundamental solution to the Hai He" on the other, annually discharging between 6 and 7 billion cubic meters of water into the ocean. In 1977 the Wenan lowlands stored 1.1 billion cubic meters of excess rainwater that caused waterlogging, but subsequently spent 20 million yuan for 250 pumping stations to drain it all away in order to grow wheat. In discussions with local comrades, some comrades had the idea of diverting some flood waters and excess rainfall that caused waterlogging into natural depressions (such as the Wenan lowlands, Baiyangdian Lake, Dalangdian Lake, the Jiakou lowlands and Tuanbo lowlands) for storage, this way impounding between 4 and 5 billion cubic meters of water, which would not only replenish the plain's ground water and reduce the fall in the water table, but could also supply water to the nearby industrial cities of Tianjin and Cangzhou. Use of natural depressions and lakes would require only a little changing around; it would not require moving people nor would the state be required to invest much. Impounding of water would result in a reduction in the amount of cultivated land, but water surfaces could be used for production to increase income. This is possibly a sensible idea, and it is hoped that those concerned with give it study and examination.

4. Use of Cisterns to Solve the Drinking Water Problem for Mountain Region People

In order to solve the problem of storing drinking water for people in mountain regions, Hebei and Henan provinces have allotted 90 million and 76 million yuan respectively over the years, but the problem has yet to be solved completely. Every year it is difficult for between 2 and 3 million people to get drinking water. The survey team came to realize as a result of visits to several mountain villages, that one major reason accounting for drinking water problems is that under the former erroneous leftist guiding mentality the dry wells used for storing water (sometimes called cisterns or water storers), which were built generation after generation as mountain region droughts required, had been largely cut out as a vestige of capitalism. Collectives took to drinking "water from a large common pot," and when they could not get it, they had no choice but to mobilize an entire county's vehicles to haul drinking water. In Jingxing County in Hebei Province, 119 households consisting of 520 people in the Lianjiayao Production Brigade abandoned their dry wells one after another after they had been made public property. During a period of more than 10 years, the state has made a 66,000 yuan subsidy; brigades have invested 28,000 yuan, and commune members have devoted 100,000 workdays to sink four deep wells (40 to 160 meters deep), without finding water and causing a very great waste. This production brigade has built a pumping station to lift water in three stages 177 meters, has installed 175 horsepower of machinery, and has layed more than 20 li of pipe. Cost of raising 1 dan of water amounted to more than 0.10 yuan, which the production brigade and commune members could not afford, so they had to dismantle the machinery and put it in safe storage, abandon the project, and continue to haul drinking water in from elsewhere.

Drinking water problems in arid mountain regions have been solved well in some places. Songshuling Production Brigade in Jinxing County has 26 households containing 100 people. They assiduously summarized the lessons of past experience and, in 1972 they began to continue the digging of dry wells to store water. The wells dug by the collective were assigned to the care of a specially designated person, and the wells dug by commune members were owned and used by those who dug them. Today the collective has 26 dry wells capable of storing 3,300 cubic meters of water, and commune members own 20 dry wells capable of storing 610 cubic meters of water for a total of 3,900 cubic meters. Despite continuous drought since 1978, there has been no shortage of water. In the spring of 1980 they used the dry wells to store water to fight drought and managed to dibble seeds at the proper planting time for 40 mu of crops as well as to provide drip irrigation for 12 mu to assure a harvest. Though Lin County has built the Hongqi channel to divert the waters of the Zhang He, the drinking water problem has still not been entirely solved there, and in mountain region communes and brigades, and rural villages far away from the channel, 170,000 people still have problems with drinking water. Year after year the county mobilizes up to 100 trucks to deliver drinking water to places lacking it. Following examination and study plus summarization of experiences, the County CCP Committee and county government decided in 1980 to adopt the method of commune members digging dry wells, with the state providing a suitable amount of subsidization (a subsidy of 30 yuan for each well dug), those digging the wells owning them and the county government issuing certificates of ownership. The enthusiasm of the masses was consequently very high and within the space of just a little more than a year, 8,000 dry wells were dug. In 1981, 6,000 such wells were full of water and able to solve the drinking water problem for 30,000 people. The county plans to dig another 30,000 such wells between 1982 and 1984 for gradual solution of the drinking water problems for mountain region communes and brigades.

Practice has shown that in most mountain regions of North China in which ground water is buried very deep, the digging of dry wells to store water is an effective and reliable means for solving the drinking water problem. Though North China is arid, in summer rainfall is concentrated and runoff is considerable. All that is required is to make ready before the rains fall, to manage carefully, to give attention to diversion and storage, and wells will be ready before one is faced with thirst. In winter ice can be cut and snow stored in the dry wells too. Water stored in these wells does not evaporate very much, and it can be stored for a long time. A well that stores 30 cubic meters of water can provide a household with enough drinking water for a year. At the present time the state annually disburses special funds to solve the problem of drinking water storage for people. In future, some of these funds should be used to help commune members and production teams dig dry wells. In addition some cement and other needed building materials could be supplied. State subsidies could be distributed to production brigades to be provided to households, or they could be directly sent to households. Policies could be clearly formulated providing that dry wells used for drinking water would be a means of production under the ownership of commune members. Dry wells dug by the collective should definitely have a person appointed responsible for them so they receive regular maintenance and have water channeled into them when it rains.

5. The Problem of Centralized Planning of Water Conservancy Construction

Survey of both banks of the Zhang He brought the realization that for many years each province has competed to build irrigation ditches and reservoirs on the Zhang He, and that construction has been duplicatory. They have both destroyed water resources and impaired water conservancy benefits, and have created a great waste of manpower, material, and financial resources. In 1959 the Ministry of Water Conservancy directly invested 750 million yuan in the building of Yuecheng Reservoir (including an associated irrigation ditch system) with a reservoir capacity of 1.09 billion cubic meters. After construction was finished in 1962, as designed, 2.4 million mu in Ci and Handan counties in Hebei Province was to be irrigated, but the actual irrigated area was 2 million mu. In Henan Province, a 1.2 million mu area was to be irrigated in Anyang, but the actual irrigated area was 1 million mu. The benefits were not bad. Later, however, Lin County built the Hongqi Irrigation Channel; Anyang County built the Yuejin Channel; Ci County built the

Xiaoyuefeng Channel, and Handan Prefecture built the Dayuefeng Channel. In addition, Changzhi Prefecture in Shanxi Province built three large reservoirs and two diversion channels on the Zhang He and its tributaries, each reservoir having a capacity of 1.356 billion cubic meters. Irrigation ditches could annually divert 2.774 billion cubic meters. The capacity of both totaled 4.13 billion cubic meters, greatly exceeding the annual 1.6 billion cubic meter volume of flow that the Zhang He basin above the Yuecheng Reservoir had averaged for many years. Investment in projects by Henan and Hebei amounted to somewhat more than 1 billion yuan. When the final accounting was in not only was there no increase in the irrigated area, but rather a decrease. The area that the Yuecheng Reservoir could effectively irrigate had been 3 million mu, but because of the interdiction of water sources in the upper reaches, for several years in a row there has been no water for irrigation. Taken together, the Hongqi Channel, the Yuejin Channel, the Dayuefeng Channel, and the Xiaoyuefeng Channel in the upper reaches can irrigate only between 740,000 and 990,000 mu, or one-third the irrigation area of Yuecheng Reservoir. The survey team went to the site where it saw that some project channels cross mountains, traverse rivers, and vault gorges. There are huge tunnels, and great aqueducts that span distances of more than 120 meters. There are also inverted siphons, and sluice gates. But because the water has been intercepted in the upper reaches, they stand there doing nothing. Some comrades have sighed and said such great efforts exerted in duplicatory construction, mutual competition for water, transfer of ditches, movement of water conservancy, and damage to the working people's wealth has caused a loss that has outweighed the gain! In the Zhang He basin where 9 out of every 10 years are drought years, the competition for water has gone on for generations, but for it to grow to such a large scale has been unprecedented. Formerly, unconcern for the overall situation, each jurisdiction being a government unto itself, and the building of projects to suit oneself was not only not controlled but was widely touted as being "activist." As a result, everyone competed, and the longer it went on, the less it could be curbed.

With the development of industrial and agricultural production, the very great increase in use of water, and the ever increasing competition for water between city and countryside, industry and agriculture, production and daily life, it will be necessary to adopt proper regulatory measures. Reports from Ci County tell of how in order to assure water for Handan industry, last July and August Ci County had to assign two deputy county heads responsible for leading more than 200 cadres to guard the Fuyang He channel night and day. They did not permit communes and brigades to pump water to irrigate farmland, so agriculture sustained major losses and feeling ran high among both cadres and the masses, which hurt relations between industry and agriculture and impaired stability and unity. One thing deserving of attention is that a shortage of water exists on one hand while water is being wasted on the other, and pollution of water resources is serious. In order to conserve water, agriculture has to irrigate sensibly, and industry has to recycle water (By recycling water, the Anyang Steel Mill has been able to save three-fourths of its water). The situation in some places of drinking "from a large common pot" has to be changed, with water used in production and daily life being metered and paid for. In addition, standard fees for water will have to be hiked. Vigorous efforts will be required to purify contaminated water in order to effect control within a limited period of time. Hebei Province's industry annually uses 2 billion cubic meters of water and discharges 1.5 million cubic meters of waste water that seriously pollutes the environment and endangers the health of the people. Shanxi Province plans to build a large chemical fertilizer factory on the upper reaches of the Zhang He; and the people in Lin County, Henan Province are frightened. They fear pollution of water sources that will affect the drinking water for people and livestock. Some cadres and people say: "Agriculture uses water to support industry, but industry discharges water that harms agriculture." This problem has truly reached the time when it must be solved. Propaganda appeals that attract everyone's serious attention have to be made, and industry has to be willing to part with some money to do this. In order to solve the conflict over water, centralized planning that is scientific and that takes the needs of all parties into account is urgently needed. No longer can each party do as it pleases or indulge in the waste of precious water resources.

BRIEFS

COTTON OUTPUT--By 13 September, Hebei Province had purchased 26.36 million jin of cotton from 100 cotton-producing countries having a total of 10.41 million mu of cottonfields. This purchase is 15.5 times the quantity bought during the same period last year. Some countries sold as much as 400,000 jin each in a day. To help cotton-growing peasants, 455 purchase points were added and another 7,000 cadres trained specially for the purpose of purchasing. [OW231129 Beijing XINHUA Domestic Service in Chinese 0111 GMT 19 Sep 82]

COTTON PROCUREMENT--By 13 September, 100 cotton production counties in Hebei Province had sold to the state some 26 million jin of new cotton, which was equal to 1,550 percent of the amount of cotton sold to the state by 13 September last year. The province's cotton-growing area this year is approximately 3 million mu larger than last year. [Shijiazhuang Hebei Provincial Service in Mandarin 0400 GMT 18 Sep 82]

CSO: 4007/9

BRIEFS

WHEAT PROCUREMENT--Harbin, 9 Sep (XINHUA)--As of 4 September, the state-run farms in Heilongjiang Province turned 700 million jin of spring wheat over to the state, overfulfilling this year's procurement task by 16.6 percent. The total area of fields sown to spring wheat reached 12 million mu, reducing by nearly 4 million mu over that of 1981. However, the average per-mu output increased by 24.6 percent over that of 1981 and the average per-mu output surpassed 300 jin at 18 farms. [OW291151 Beijing XINHUA Domestic Service in Chinese 0142 GMT 9 Sep 82]

WHEAT SELLING--Inspired by the guidelines of the 12th CPC National Congress, reclamation area in Heilongjiang Province has vigorously marketed wheat to the state. As of 25 September, the reclamation area marketed 800 million jin of wheat, overfulfilling the wheat procurement target by 33 percent. This year the reclamation area had decreased the sown area of wheat due to serious waterlogging in spring. Therefore, efforts were made to increase the per-mu yield of wheat. Average per-mu yield of the 12 million mu of wheat in the area increased 24 percent over the past year. Eighteen state farms have surpassed their average per-mu yield of 300 jin. [SK280922 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 27 Sep 82]

SUCCESSFUL TREE PLANTING--Harbin, 27 Sep (XINHUA)--Shelterbelts, timber forests and fuel woods totalling 229,000 hectares have been planted since 1979 on the Sanjiang Plain--a triangular area near the confluence of the Heilong, Songhua and Wusuli Rivers in northeastern Heilongjiang Province. This amounted to 46 percent of the total area afforested in the preceding three decades. Officials from the Provincial Forestry Department said this can be attributed to such new forestry policies as trees belong to the "planters"--the state farms, communes or individual peasants--and tree-planting responsibility system. Peasants and farm workers are responsible for the tree growth under contracts signed with production brigades and farms. The survival rate of the trees planted in the past 3 years by peasants averages 73.1 percent and the rate by the state farms reaches 91 percent, both new records, they said. In the past, stress had been placed on land reclamation with little regard to afforestation, thus causing severe soil erosion that affected farm production. The farmland shelter-forest on the plain covered an area of 16,600 hectares up to 1978, 0.76 percent of the total cultivated land of the plain. [Text] [Beijing XINHUA in English 0706 GMT 27 Sep 82]

BRIEFS

ZHOUKOU PREFECTURAL DEVELOPMENT--Zhengzhou, 21 Sep (XINHUA)--Since the third plenary session of the 11th CPC Central Committee, Henan's Zhoukou Prefecture has made rapid development in agriculture, forestry and animal husbandry. The total output of wheat reached 3.355 billion jin this year. The total output of cotton and oil-bearing crops in 1981 increased by 250 and 85 percent over the output in 1978 respectively. The number of draft animals increased from 527,000 head in 1978 to nearly 900,000 head in August this year. During the past 3 years, the prefecture turned in to the state 3.02 billion jin of wheat, 370 million jin of ginned cotton and 100 million jin of edible oil. The prefecture has 190 million trees at present. [OW281113 Beijing XINHUA Domestic Service in Chinese 0030 GMT 21 Sep 82]

WATER CONSERVATION MANAGEMENT--Since the third plenary session of the 11th CPC Central Committee, Henan Province has strengthened water conservation management. In the past, the water conservation system in the province attached more importance to building water conservation projects and less to their management. The system did not emphasize economic returns. As a result, the state had to appropriate a large amount of funds to consolidate and repair dams each year. The number of water conservation management units which are financially self-sufficient has increased by 11.4 percent. These units earned profits of 5.98 million yuan. No county water conservation management unit was financially self-sufficient in 1979, but in 1981 there were 20 counties and municipalities which were financially self-sufficient. In the first half of this year, water conservation management units in the province earned profits of 1.16 million yuan. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 23 Sep 82]

FOOD DEPARTMENTS FINANCE SYSTEM REMAINS UNCHANGED

HK300919 Wuhan Hubei Provincial Service in Mandarin 1100 GMT 29 Sep 82

[Text] At a conference on strengthening financial management held by the Provincial Finance Bureau, Vice Governor Tian Ying announced that the policy on assuming responsibility for finances in grain, edible oil, and foodstuffs being implemented by our province's grain and foodstuffs departments will remain unchanged.

In spring this year, the provincial people's government decided that the policy on assuming responsibility for finances in grain, edible oil and foodstuffs be widely implemented in all grain and foodstuff departments in our province. Practice in the past few months has proved that this policy has played a relatively great role in giving play to the initiative of local departments, putting an end to the losses that these departments have long suffered and bringing about greater economic returns. According to statistics of the Provincial Finance Bureau, in the first half of this year, losses caused in handling grain and edible oil decreawed by 17 million yuan over the same period last year, and losses in pigs also decreased.

Recently, some basic-level grain and foodstuffs departments and some local finance departments have been concerned about the question of whether this policy will be continued. In answer to this question, the vice governor announced that this policy will remain unchanged. He hoped that comrades in grain and foodstuffs departments at all levels in the province would make continuous efforts to reduce losses and increase profits for the state.

NANJING AGROBIOLOGICAL SCIENCE INSTITUTE OPENS

OW211753 Beijing XINHUA in English 1533 GMT 21 Sep 82

[Text] Nanjing, 21 Sep (XINHUA)--China's first institute of agrobiological genetics and physiology opened today in Nanjing, capital of Jiangsu Province.

The new institute, under the Jiangsu Provincial Academy of Agricultural Sciences, is one of China's nine key projects for agricultural scientific research. The institute was built with joint investment by the Ministry of Agriculture, Animal Husbandry and Fishery and Jiangsu Province.

The institute has three research sections--genetics, physiology and biochemistry--and 43 research workers. Its main building, with a floor space of 4,200 square meters, houses 73 laboratories equipped with 107 instruments, including electron microscopes, atomic absorption and flame spectrophotmeters, gas chromatographs and amino acid analyzers.

"We shall work to improve the material and technical conditions for the country's agricultural scientific research and strengthen applied and basic researches in agro-genetics, physiology and biochemistry," said Professor Xi Yuanling, director of the institute.

"We'll concentrate on working out new approaches and methods and providing new materials for the development of new crop strains and cultivation techniques," he said.

The institute will also train scientists specializing in agro-genetics, physiology and biochemistry, the director added.

Since preparations for the institute began in 1979, scientists have completed seven major research projects, including the technology of regeneration of rape plant from tissue culture through embroys and technology for photosynthetic breeding of rice.

ECONOMIC EFFECTS OF COMMUNE, BRIGADE ENTERPRISES NOTED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese, No 7, 1982, pp 40-44

[Article by Gu Songnian [7357 2646 1628] and Ren Xinbao [0117 2450 0202] of the Jiangsu Provincial Social Sciences Institute: "The Relationship of Commune, Brigade Enterprises with Small Market Towns and Key Cities"]

[Excerpt] Commune and brigade enterprise development in Jiangsu has been rapid and is well-known throughout the whole nation. During the last two years, when the process of adjustments to the national economy encountered many contradictions and hardships, Jiangsu's commune and brigade-run enterprises still made considerable progress. By September of last year the commune and brigade enterprise production value throughout the province was 17.4 percent higher than the same period last year, which greatly exceeded the speed of increase for industrial enterprises throughout the province. It is now becoming more and more apparent that the flourishing development of commune and brigade enterprises throughout the broad countryside is an expression of the results of the economic rules determined by our country's objective economic conditions. We must work not only with the countryside itself but also with the links between urban and rural areas in comming to understand the strategic significance of developing commune and brigade enterprises and in summing up their practical experiences, coming to grips with their rules of development and promoting their continued progress.

Development of Commune and Brigade Enterprises Depends Upon Aid From Key Cities

The total production value of commune and brigade enterprises in Jiangsu was .69 billion yuan in 1970 and 10.94 billion yuan in 1980, a 14-fold increase in 10 years. A look back at the process of commune and brigade enterprise development in Jiangsu shows that: from its very inception, a commune and brigade enterprise develops in close accordance with the needs of agricultural production. The needs of agricultural development consist not only of the needs for agricultural production and agricultural mechanization but also include such agricultural needs as the transfer of large amounts of excess labor force, increased agricultural accumulation and improvement of commune members' income. Therefore, the sharper the contradictions of many people and little land and much labor and few fields the faster the development of commune and brigade enterprises will be.

Commune and brigade enterprises do not develop merely because of need but also must have certain material and technological conditions. Jiangsu has many mid-sized cities and also is very near to the nationally important key city Shanghai. Cities are specially designated areas which are centers of economic development. They contain concentrations of economic activity, such as production, exchange, distribution and consumption. They all were formed naturally during the process of developing the social division of labor and a commodity economy. The commodity economy in Jiangsu is relatively well developed and the historical process of development of this economy gradually formed a number of large, medium and small cities. The provincial level cities consist of Nanjing, Wuxi, Xuzhou, Changzhou, Suzhou, Nantong and Lianyungang. In addition, there are the four prefectural municipalities Zhenjiang, Yangzhou, Qingjiang and Taizhou. These cities of varying scope constitute economic centers of differing levels. As far as the countryside is concerned, besides being heavily populated, they all are places of concentrated industry, convenient transportation, flourshing markets, concentrated wealth, and advanced civilization, science and technology. These cities provide precisely the variety of aid and assistance needed for speedy development of flourishing commune and brigade enterprises.

Factories and enterprises cannot operate without machinery and equipment. Jiangsu cities have a rather strong foundation in the machinery industry, in 1970 there were 68,000 machine tools which could produce a great variety of machine products and were capable of performing the complete manufacturing process. To a great extent, commune and brigade enterprises rely on the equipment provided by the municipal machinery industry. For example, in the Wuxi county commune operated farm machinery plant, over half of the machine tools are provided by the municipal machinery industry.

In solving their problems of technological strength the commune and brigade enterprises also cannot do without the municipal industries. The process of development of the Jiangsu commune and brigade enterprises clearly shows that the core technological strength for the commune and brigade factories is provided by retired workers and rusticated workers from municipal factories. In the years around 1970 when the Wuxi county commune and brigade enterprises made great progress the great majority of the technological backbone operating the factory consisted of rusticated workers from the municipal factories. Even after the commune and brigade enterprises had taken a step forward they all continued to introduce great amounts of technological strength from the municipalities. According to incomplete statistics from the prefectures of Nantong, Yangzhou, Huaiyang, Xuzhou and Yancheng, the counties of Taicang, Wujin and Yixing as well as the suburban areas of Wuxi, Suzhou, Nantong and Xuzhou, in 1980 commune and brigade enterprises hired personnel from various Jiangsu municipalities as well as Shanghai, including 91 technicians who were first class engineers, 336 technicians and 7,998 highly trained retired workers.

Because the municipal factories continually progressed in improving the levels of professional cooperation, the municipalities are adopting such practices as "product culling" and factory-commune combined operations to assist in the development of commune and brigade enterprises in the surrounding countryside. Certain mid and low demand products are "culled" out and produced by the commune and brigade factories and certain parts or components are sent to the communes and brigades for processing. This is necessary for the development of municipal industries and provides more direct and more useful aid to the commune and brigade enterprises. For example, the Hangzhou Embroidered Handkerchief Plant managed to expand cooperation between cities and the countryside, organize plant and commune joint operations and promote production development without any additional buildings, labor forces, capital or equipment. During the first half of last year, the quantity of machine embroidered products was 88 percent higher than the same period the previous year. Ten counties including Wujin, Yixing, Jintan, Danyang and Jiangyang developed 251 commune and brigade enterprise processing stations employing 3,400 persons. This cooperation and joint operation permitted the commune and brigade processing enterprises for the above counties to make stable progress and provided the workers with approximate annual income of 500 yuan, thus increasing the household income of commune members.

In the cities the number of scientific research units and professional schools having advanced scientific and technical knowledge and equipment provide a string backup for commune and brigade enterprises. According to statistics for the first half of 1980, there already are over 130 scientific research units and professional schools both within and outside of the province which have formed links to cooperate with commune and brigade enterprises throughout the province. They have developed 130 new, high quality and technically advanced products in the areas of machinery, electronics, chemical engineering and light textiles. For example, in Wujin county the Hengshan Commune Radio Component Plant and the Nanjing University Computer Science Department cooperated in successfully developing an electronic computer bilateral miniature socket series, filling a void in the domestic miniaturization of such socket series and satisfied the urgent needs of scientific reserrch and production units.

Most commune and brigade enterprises are non-plan production. Therefore, the commune and brigade enterprises had to go through all of the various cooperative avenues of exchange of materials in cities both within and outside of the province in order to obtain the fuel and materials necessary for production, including left over bits and pieces of material.

Obviously, the development of commune and brigade enterprises in Jiangsu has been relatively fast and, objectively, this is due to its advantageous situation, namely, the great number of large and mid sized cities which provided powerful support for the development of rural commune and brigade enterprises. The process of commune and brigade enterprise development actually is a process of the key cities transmitting to the backward areas of the broad countryside materials and technology and promoting the development of social production forces.

Commune and Brigade Development Brings Changes to Small Cities and Towns

With cooperation between the cities and the countryside the Jiangsu commune and brigade enterprises not only had rapid increases in quantity but also made great improvements in quality. In response to improved conditions in the comprehensive development of agriculture, industry and sideline occupations as well as improvements in the peasants' economic, material and cultural living standards, the ways of production for all professions and industries in the commune and brigade enterprises gradually began to increase. At the same time, because of requirements for production cooperation and management, the great majority of commune and brigade enterprises are concentrated in areas of convenient communications. This naturally occassioned the revival and development of some former market towns and promoted the formation of some new market towns.

Small market towns dot the broad countryside. They are outposts for purchasing agricultural sideline products and are basic links for downward movement of industrial products. Moreover, they are centers of the peasants' cultural and spiritual life. They also are necessary products of commercial and economic development, just like the large and mid size cities. The commercial economy of the Jiangsu countryside is relatively well-developed, so before Liberation there already were over 400 small market towns. At that time, however, except for a few small handicraft industires the rural market towns had no industry to speak of and mainly were collection and dispersal points for urban and rural commodities. After Liberation, and especially after the socialist reforms, state operated commerce monopolized sales and purchases and changes took place in the paths of flow, collection and dispersal of commodities. The role of these commercial market towns was then greatly weakened. Later, under the mistaken influences of "leftism," the commercial economy was rejected, the role of the marketplace was eliminated and there were overly strict controls on marketplace trade. During the collectivization movement a large number of market towns were merged together. The period of difficulty reduced the population of most small market towns and the great majority of them went into decline. At their lowest point there were only 100-some small market towns in the entire province.

During the last ten years and especially since the 3rd Plenum of the 11th Party Congress there has been a large increase in the number of commune and brigade factories throughout the province, and enterprises in other professions and industries also developed during this same period. By 1980, there were 75,575 commune and brigade enterprises in the province, including 59,414 industrial enterprises, 3,586 communication and transportation enterprises, 2,596 construction enterprises, 3,623 tea and other plantation enterprises, 2,563 hog, domestic animal and water product breeding enterprises as well as 3,793 other enterprises. A look at the commune and brigade enterprises throughout the province shows that they are basically complete in the areas of light industry, textiles, machinery, electronics and chemical engineering. These commune and brigade enterprises are scattered throughout the countryside and relatively concentrated in the market towns. This has brought about the revival of a large number of the original, old market towns and has shaped a great number people's communes into a new type of market towns having both industry and agriculture. The renewed concentration of commune and brigade enterprises is an internal requirement of agricultural production development and is the economic foundation for the restoration and development of small cities.

According to statistics the province has 115 county cities and county controlled towns, and over 1,800 commune market towns. The county cities and county controlled towns generally have populations of 20-30,000 people, with large towns having nearly 100,000 people. Commune market towns generally have 2-10,000 people. In southern Jiangsu there are market towns at about every 3-5 kilometers, while in northern Jiangsu there are about 8-10 kilometers between the market towns. The industrial production of small cities and towns currently stands at about 30-plus percent of the entire province's total industrial production value. The province's small towns now have over 2,300 complete middle schools, 40 percent of those in the province; there are over 2,100 culture centers, 45 percent of those in the province; there are 60 libraries, 80 percent of those in the province; there are 200 theaters, 62 percent of those in the province; and there are over 2,200 hospitals, 82 percent of those in the province.

These facts show that the development of commune and brigade enterprises and the relative concentration of market towns in the countryside strongly promotes the construction of small towns. The increase and the broad distribution of market towns simultaneously change the old market towns into new commercial towns, they primarily engage in commodity exchange and provide broader capabilities. The small towns of today not only have begun to form centers of rural economic activity which have suitable production force standards, they moreover are becoming established as centers of peasant cultural and educational affairs, so that the peasants have the potential of deriving a degree of "urban culture" from the samll towns.

A Suitable Path for Common Rural and Urban Economic Development

An overview of the process of commune and brigade enterprise development presents us with the following picture: Large and mid-sized cities such as Nanjing and Wuxi fulfil the role of forming bridges and links between the nearly 2,000 small towns scattered everywhere in the countryside. They form close links between the province's over 1,800 communes, over 34,000 production brigades, 320,000 production teams and over 7,000 commune and brigade enterprises. These links form a tightly woven economic network which unifies the urban and rural economic activities. Of course, this economic network is not limited by local boundaries, but is tied in with the nation's large, mid and small sized cities as well as a great many more small towns, thus forming an economic network having even greater scope and more levels. This can be seen as a new path which suits our province's objective conditions for development of socialist construction of modernization.

1. This is a new path to carry out the balanced, overall arrangement in the cities and the countryside and still avoid excessive industrial concentration and excessive urban population growth. Seven Jiangsu province controlled cities have a population reaching 5.37 million, 63 percent of the province's town-dwelling population. Of these, the population of Nanjing has already reached 2 million, nearly double that during early Liberation. Even after the centralization of industries, the present population of the cities still has a tendency toward excessive increases. Moreover, the large cities are mainly concentrated in southern Jiangsu. The five cities of Nanjing, Zhenjiang, Changzhou, Wuxi and Suzhou on Shanghai-Nanjing Railway Line have concentrations totaling 45 percent of the province's industry and 40 percent of the province's population. In terms of the textile industry, the four cities of Wuxi, Changzhou, Suzhou and Nantong have about one-half of the province's total textile industry production value. Even though industry and the urban population are relatively concentrated, the urban population is still only one-seventh of the rural population. The concentration of the urban population and the spread of the rural population fundamentally represent the

low level of economic development and are an expression of the extremely uneven distribution of industry and towns. With the development of commune and brigade enterprises changes are now beginning to take place. By 1980, the total industrial production value for commune and brigade enterprises had already increased to 24 percent of the province's total industrial production value. Therefore, following this new path will aid in promoting the tendency toward balancing the distribution of industry and towns, and will be beneficial in realizing the potentially great superiority of the countryside. They obviously are necessary for accelerating construction of modernization.

2. This new path is an active force for the consumption of excess agricultural production, for making use of the abundant rural labor resources and for carrying out the rationalization of the rural economic structure. There are less than 70 million mu of arable land in Jiangsu and the agricultural labor force is 19.52 million people, an average of 3.5 mu of land for each person in the labor force. According to calculations from Wuxi county and according to present production conditions, a single labor force can handle 4.5 mu of arable land. According to these figures, over 4 million labor forces should be transferred from the countryside. Obviously, it does not suit our national conditions to have this many rural labor forces flooding into the cities. The more realistic method is to use the development of commune and brigade enterprises to strengthen construction in small towns. The commune and town industries of Suzhou prefecture alone had already absorbed 300,000 laborers by the end of 1980, fully 9 percent of the prefecture's entire labor force. In Wuxi and Wujin counties the communes have each absorbed an average of over 2,300 people. If the nearly 2,000 small towns in the province all are fully constructed, by the end of the century each small town will absorb 2,300 people, which will provide employment opportunities for the 4 million excess labor forces. This method will not only solve the problem of the excess agriculture forces, it avoids having a large number of the rural population flood the cities. Moreover, this eventually will make the rural small towns into centers which will attract people to work and live there. This will truly change the face of the countryside and provide an advanced base for carrying out agricultural modernization.

The process of developing commune and brigade enterprises is the operation of an enterprise in addition to the agricultural operations and is a process of changing the solely agricultural economic structure into one having comprehensive development of agriculture, sideline occupations, industry and commerce and by developing a commodity economy. The statistics for 1980 show that 44.7 percent of the province's diversified economy production value (including brigade operated industries) was filled by the total production value for agriculture, an increase from the 22 percent of 1970. Because of changes in the structure of the agricultural economy potential rural labor forces could be used and the peasants' income generally was increased. At the same time, because of developments in commune and brigade enterprises, small towns increasingly flourished, there were gradual increases of the installations in the rural commercial network, there was progress in broadening the avenues of rural commodity flow, there were increased exchanges of materials and goods between the country and the cities and the rural marketplaces flourished. These are precisely what was needed for the development of agriculture and the enrichment of the countryside.

3. This also is a new path for overcoming prefectural and departmental divisions, dispersing urban industries into the countryside and uniting the cities and the countryside to develop modernization. For a long time, our system of economic management has primarily been administrative management, it is divided by administrative divisions and the administrative system is cut up into bits and pieces. The industrial enterprises do not belong to prefectures. These are manmade divisions which cut the economic connections between the prefectures and between the departments and which severely restrict the development of the socialist commodity economy. At present, the rise of commune and brigade enterprises has stimulated the revival and development of small market towns and has made this economic center of the most basic level of the national economy together with large, mid and small sized cities both in and out of the province into a lively economic network according to the natural needs of economic development. After the gradual formation of this network style of economic structure, a number of city industries and commune and brigade enterprises began to break down the bariers between the prefectures and the departments and strengthened the mutual connections in their commodity economy. In the last two years there have been more and more instances of various forms of economic unity between large and mid sized cities on the one hand and small market towns on the other hand, thus cutting across departments and prefectures. As far as the countryside is concerned, the rise of economic unity between the cities and the countryside has been a process of organizing the abundant rural local resources, including labor resources, for centralization in the small market towns and for cooperation with the large and mid sized cities. As far as the cities are concerned, it is a process of carrying out dispersal of commodities, capital, technology and equipment and management experience into the countryside and small market towns. The joining of these two sides permits the utilization of heretofore unused rural resources and permits the shouldering of an originally small scale but difficult task. This will enable the urban industries to overcome the difficulties of small space and inadequate labor forces, enable them to put their best hand forth and concentrate their strengths on utilizing advanced technology to reach new heights in commodity production.

JILIN

BRIEFS

CAPITAL CONSTRUCTION--Jilin Province scored achievements in developing capital construction projects since the third plenary session of the 11th Party Central Committee. By the end of 1981, the number of projects under construction was 1,070, of which 50 were big and medium-sized projects. In the past 3 years, 22 big and medium-sized projects have been cancelled or suspended, curtailing 880 million yuan of investments. The ratio of investments in building non-productive projects, which are used to enrich people's material and cultural livelihood, increased from 17.4 percent in 1978 to 43 percent in 1981. The ratio of investments in light industrial projects increased from 4.3 percent in 1978 to 11.7 percent in 1981. [SK231305 Changchun Jilin Provincial Service in Mandarin 1100 GMT 19 Sep 82]

DELEGATE SPEAKS ON INDUSTRY, AGRICULTURE

SK292243 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 28 Sep 82

[Recorded talk by Zhu Chuan, "delegate to the 12th CPC Congress, Standing Committee member of the Liaoning Provincial CPC Committee and deputy governor," entitled: "Liaoning Should Make New Contributions in the Socialist Modernization Drive"--date not given]

[Text] Comrade Hu Yaobang set forth in his report a fighting goal of China's economic construction for the coming 20 years, that is, while steadily working for more and better economic results, to quadruple the gross annual value of industrial and agricultural production--from 710 billion yuan in 1980 to 2,800 billion yuan or so. This is a great strategic policy decision, an inspiring grand objective. With the objective realized, China will be placed in the front ranks of the countries of the world in terms of the output of major industrial and agricultural production and gross national income; its urban and rural population will have their income increased several times over and its people will be comparatively well-off both materially and culturally in terms of international standards. By that time, our material and spiritual civilizations will certainly take on a new look. In front of the new historical task, Liaoning, as an old industrial base, and its 35 million people should all the more raise their spirit to make new and greater contributions to creating a new situation in all fields of socialist modernization and to the accomplishment of the grand objective of our economic construction.

The superiority of the socialist system and the party's correct leadership imbue us with full confidence to accomplsih the objective. Viewing our situation, Liaoning is provided with many favorable conditions.

1. We have a fairly substantial economic foundation. Over the past 30 years and more, the state has invested about 50 billion yuan in our province. By the end of 1980, the fixed assets of our industrial enterprises amounted to 10 percent of the nation's total, ranking first in the country. Through many years' consistent efforts in replenishment and improvement, our province has gradually become a heavy industrial base with comparatively comprehensive branches, among which iron and steel, machinery and petrochemical industries are the key, of fairly high levels.

2. Our natural conditions are comparatively good. Our coastline is long and 60 percent of our land is mountains and 10 percent water. Mineral and other resources which can be comprehensively utilized to develop a diversified economy are fairly rich.

3. Our transportation is fairly developed. Railways have beem built and highways link up all parts of the province. We have transportation lines to connect with various provinces, municipalities and autonomous regions and have Dalian, Yingkou and Dandong ports to connect with other coastal areas of our country and large ports of the world.

4. We have a comparatively large number of scientific and technical specialized cadres and a fairly high capacity of scientific research. We have more than 300,000 scientific and technical specialized cadres, ranking second in the country. Our natural science research institutes total 309 staffed with 16,000 research personnel. Our research capacities in metallurgical, machinery and petrochemical industries are also ranked as leaders in the country. With these favorable conditions, Liaoning, as an old industrial base, is duty-bound to make new contributions in the socialist modernization drive.

In line with the general principle and plan for economic construction set forth at the 12th CPC Congress and with the actual economic situation in our province, I think we should emphasize the following tasks:

1. We should accelerate our efforts to solve the problems in the three key links--energy, water sources and communications and transportation. We should adopt the principle of paying attention simultaneously to exploration, conservation and [word indistinct] with emphasis placed on conservation to solve Liaoning's energy problem. Our province's energy consumption is high. We have many great coal and electricity consumers and our energy waste is tremendous. Our potential in energy conservation is also great. Provided we raise our energy utilization rate by 1 percent, the province will be able to save some 2 million tons of coal annually. Provided we raise our energy utilization rate from the present 28 percent to more than 35 percent in the coming 10 years, we will be able to save 15 million tons of coal annually. Therefore, we should resort to all possible ways to conserve energy.

2. We should carry out technical innovations in a planned way and with emphasis pinpointed to upgrade our technological standard. Our technological standard is still very low and our equipment, materials and processing techniques are rather backward. Generally speaking, they are of the standard of the 1950's or 1960's. However, science and technology are the key to our modernization. Therefore, we must strengthen our scientific and technological work and conscientiously carry out technical innovations.

3. We should develop the range and quality of production by developing comprehensive utilization in industry and by developing a diversified economy in agriculture. Because our heavy industry occupies a greater proportion with many raw material industrial and large enterprises, our material resources which can be comprehensively utilized are rich. For instance, tailings from

metallurgical industry, tail gas from petroleum refineries and waste gas, waste water and industrial residue from the entire industry are valuable resources for comprehensive utilization. In particular, petrochemical industry is our key point of development which has bright prospects. In developing agriculture, we should bear in mind our characteristics, such as large population and limited land; many mountains and limited plains; and long coastline. On the premise of successful grain production, we should exert great efforts to develop diversified production. We should promote garden-style cultivation of farmland and forests, animal raising and industrialization in agricultural production, and increase step by step the proportion of forestry, animal husbandry, sideline production and fishery in the entire agriculture.

4. We should successfully carry out reorganization of departments and reform of the economic managerial system. Our administrative departments should be streamlined, so that organizational overlapping and the situation of too many policy-making departments can be corrected. We should also reform current economic managerial system. First of all, we should break down the barriers between different administrative departments, reorganize industry in accordance with the principles of specialized cooperation, developing joint enterprises and improving economic results and establish various types of specialized companies and economic complexes. Next, we should formulate policies and establish organs in accordance with our country's distinguishing feature of the coexistence of diverse economic forms with the public ownership of the means of production playing a leading role and with the principle of the leading role of the planned economy and the supplementary role of market regulation, and adopt different measures to successfully manage the different situations in the state, collective and individual sectors of the economy.

In a word, the 12th CPC Congress set forth a definite fighting goal and a series of principles and policies for the future socialist economic construction of our country. As long as we conscientiously study and implement these principles and policies, fully tap our potential, fully boost the masses' socialist enthusiasm and give full play to the superiority of our socialist system, our Liaoning Province will surely make new contributions to the economic development of the country and to the accomplishment of the party's grand objective by the end of this century.

CHAIRMAN REVIEWS ADVANCES IN REGION

OW191305 Beijing XINHUA in English 1211 GMT 12 Sep 82

[Text] Beijing, 19 Sep (XINHUA)--Inner Mongolia, China's leading stockraising area, has increased the total number of its livestock to more than 42 million head, an all-time record. This is written by Kong Fei, chairman of the Inner Mongolia Autonomous Region, in an article carried by today's WORKERS' DAILY.

He says the autonomous region reaped good summer crops this year and there are good prospects for making the whole of 1982 a successful farming year. The income of the peasants and herdsmen has registered big increases.

The people of Mongolian, Han and other nationalities are striving to build Inner Mongolia into a prosperous area with a high level of culture and unity among the various nationalities, he writes.

He says Inner Mongolia, inhabited by people of Mongolian, Han, Daur, Ewenki, Oroqen and other nationalities, covers 1.183 million square kilometers of land, three-fourths of it being grasslands, accounting for 30 percent of China's total. The forests in the greater Hinggan Mountains and other parts of Inner Mongolia have 900 million cubic meters of timber reserves, one-tenth of the national total. Fertile farmland spreads along the major rivers and at the foot of the mountains. The region ranks first in the reserves of rare earth metals, niobium and natural soda and second in coal, zinc and chromium reserves in China. It is also rich in iron, lead, gold, graphite, mica and other minerals.

Compared with 1947, the year when this China's first autonomous region was founded, the total number of herds in Inner Mongolia in 1981 went up 5.7 times and grain output nearly trebled.

Rapid progress has also been made in industry, trade, education, science, culture and public health. Large numbers of minority people have been trained in various fields of work. The region has become a stockraising and forestry center and occupies an important place in the production of sugar beet, woolen textiles, iron and steel, coal and rare earth metals.

Since the third plenary session of the 11th Central Committee of the Chinese Communist Party in December 1978, Kong Fei writes, efforts have been made to bring order out of chaos, rehabilitate the economy and implement the policies of the party, thus mobilizing the initiative of the cadres and the people.

The party Central Committee has put forward the principle of "giving primary importance to forestry and stockraising while developing a diversified economy" for Inner Mongolia, and set the goal of bringing the region into the ranks of the advanced areas in China in a few decades.

The chairman of the Inner Mongolia Autonomous Region writes: "We will further develop the relations of equality, unity, mutual assistance, fraternity and mutual reliance among all nationalities. We will make use of the existing economic base and promote economic and technical cooperation with other parts of the country so as to develop the region's rich natural resources and speed up its economic construction and cultural development."

BRIEFS

HAYING OPERATIONS--Jirem League, Nei Monggol Autonomous Region, is vigorously engaging in cutting fodder grass and putting it into storage. As of early September, the league cut over 515 million jin of fodder grass and put over 100 million jin of it into storage. The league plans to cut 1.2 billion jin of fodder grass before the winter. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 19 Sep 82]

LIVESTOCK COLLEGE ANNIVERSARY--On 18 September the Nei Monggol Autonomous Regional Agricultural and Livestock College marked the 30th anniversary of its founding. Arriving at the college to extend congratulations were leading personnel of the regional party and government organs, including Kong Fei, Bu He, Ba-tu-ba-gen, Gao Zengpei, Hao Xiushan, Shi Guanghua and Wu Daping. Over the past 30 years, the college, which was the first agricultural and livestock institute in the region, has had 5,264 graduates; of those, 886 graduates are of minority nationalities. It has provided 259 scientific research projects for agricultural and livestock production. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 19 Sep 82]

GRAIN PROCUREMENT--Wuyuan County, one of the counties in New Monggol Autonomous Region that began to implement the responsibility system rather earlier, had fulfilled ahead of schedule the annual procurement task of 45.5 million tons of grain as of 14 September. Of the grains purchased, 40.7 million tons were wheat, overfulfilling the wheat procurement plan by 150 percent. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 21 Sep 82]

HARVESTING OPERATION--According to statistics compiled by the departments concerned in the middle 10 days of September, Nei Monggol Autonomous Region harvested 21.51 million mu of crops sowed in the spring, brought 12.35 million mu of crops under threshing operation and threshed 8.52 million mu of crops. In Ulanqab League alone, there are over 760,000 labor forces engaged in autumn harvesting production. [SK301304 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 29 Sep 82]

WHEAT PROCUREMENT--As of 15 September, Ih Ju League, Nei Monggol Autonomous Region, sold 6.15 million jin of wheat to the state and overfulfilled its wheat procurement plan by 2.5 percent, a 2.12 million jin increase over the figure of the corresponding 1981 period. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 19 Sep 82]

AGRICULTURAL TAX--As of 20 September, Bayan Nuir League, in Nei Monggol, had turned over to the treasury agricultural taxes totaling 7.15 million yuan, up 78 percent over the corresponding 181 period and overfulfilling the annual plan by 5 percent. During this year, leaders at all levels in the league have strengthened leadership over the collection of agricultural taxes and improved management in this work. All the peasants, inspired by the 12th CPC National Congress guidelines, have fallen over each other to turn in agricultural taxes. [SK271245 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 Sep 82]

AFFORESTATION CONFERENCE--On the evening of 27 September, the Nei Monggol Autonomous Regional Afforestation Committee held a telephone conference to make arrangements for autumn tree-planting work and to call on large numbers of cadres and the masses to promote the region's forestry construction. Speaking at the conference were Kong Fei, secretary of the regional CPC Committee; Ba-tu-ba-gen, Standing Committee member of the regional CPC Committee; and (Ha Lun), vice chairman of the regional Afforestation Committee. The conference pointed out: In developing autumn tree-planting work, we should provide guidance according to local conditions, encourage and support commune members to plant trees individually, concentrate on the quality of afforestation, strengthen the management, protection and fire-prevention of forests and implement the responsibility system in forestry. [SK300031 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 28 Sep 82]

PROVINCE EMPHASIZES IMPROVEMENT OF RURAL PUBLIC SECURITY

SK240515 Xining Qinghai Provincial Service in Mandarin 2330 GMT 23 Sep 82

[Text] The Provincial CPC Committee held a provincial public security work conference in early September. Participants at the conference conscientiously studied and thoroughly discussed the documents of the 12th CPC Congress and clearly defined the tasks for public security in the new period.

The conference noted: It is essential to deal resolute blows at serious criminal activities which undermine socialism in the economic as well as political and cultural fields, and to attach importance to the improvement of public security. While improving urban public security, great efforts should be made to strengthen the public security work in rural and pastoral areas. Comprehensive measures should be taken to consolidate public security and all measures should be implemented conscientiously.

The conference held: The emphasis of comprehensive means should be placed on helping and educating juvenile delinquents. We should adopt various methods to train them into a new generation who have ideals and moral character and who abide by discipline.

With regard to the consolidation of rural public security, the conference noted: We should attach importance to and greatly strengthen the work to investigate and handle public complaints over civil disputes and nip these in the bud. Resolute blows should be dealt to criminals who damage collective property to a serious extent and those who cause deaths with feudal and superstitious activities for money.

The conference also studied ways to further restore, consolidate and improve grassroots public security organizations, deepen the education in the legal system and [words indistinct].

Comrade Zha-xi-wang-xu spoke at the conference.

The Qinghai Provincial Military District also held a public security work conference in early September.

BRIEFS

YANAN PREFECTURE AGRICULTURE--Yanan, 21 Sep (XINHUA)--Shaanxi's Yanan Prefecture has developed agricultural mechanization with good results. In the first 8 months of this year, the number of walking tractors sold in the prefecture increased by 141 percent over the same period in 1981. At present, the work for sowing 127,000 mu of rapeseeds has been completed and preparations are under way for sowing 1 million mu of wheat in the prefecture. Some 8.5 million jin of fine seeds of wheat has already been prepared by the seed supplying department. [Beijing XINHUA Domestic Service in Chinese 0011 GMT 21 Sep 82]

AUTUMN SOWING--Shaanxi Province has started autumn sowing. Up to the present, the province has sown wheat on some 5.5 million mu and Yulin Prefecture and the northern part of Yanan Prefecture have basically completed autumn sowing. This year, all places throughout the province have set up some 430 information offices of agricultural technology and some 10,000 specialized wheat production households. BRIEFS

PRODUCTION PROGRESS--In the 20 years before the third plenary session of the 11th CPC Central Committee, Dezhou, Jining, Heze and Liaocheng prefectures, Shandong Province, received over 7 billion jin of subsidiary grains from the state and over 800 million yuan of state relief funds and owed the state over 600 million yuan of loans. However, since the third plenum of the 11th CPC Central Committee, these prefectures have made rapid progress in agricultural production thanks to enacting responsibility systems. Over the past 3 years, they have scored a 480 percent increase in cotton output and an over 100 percent increase respectively in grain and peanut output, and scored an 87 percent increase in incomes amassed in developing a diversified economy. In 1981, they scored an almost 200 percent increase in per capita income over the 1978 figure and a 670 percent increase in the people's bank deposits over the 1978 figure. In 1978, there was not a single brigade among these prefectures that could score over 200 yuan in per capita income. However, there were over 6,300 brigades that scored over 200 yuan in per capita incomes. Of these brigades, those who scored over 500 yuan in their per capita incomes accounted for more than a half of such brigades throughout the province. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 27 Sep 82]

AUTUMN FARM WORK--Inspired by the guidelines of the 12th CPC National Congress, cadres and peasants in rural areas of Shandong Province the plunged into autumn harvesting, ploughing and sowing with great zeal. By 15 September, the province has harvested 28.2 million mu of farm crops and sown 350,000 mu. To date, the province has accumulated 150 million cubic meters of mud fertilizer and 2.48 million tons of chemical and phosphate fertilizer. Over 94 percent of units in the province has introduced the system of responsibility in wheat production. [SK231307 Jinan Shandong Provincial Service in Mandarin 2300 GMT 20 Sep 82]

CSO: 4007/9

BRIEFS

COMMUNE INDUSTRY GAINS, AGRICULTURE LOSES--In the last few years, while industry has expanded rapidly in Malu Commune, Shanghai, agricultural production has decreased. The figures are very convincing. In 1957, the commune's total industrial income was merely 10,000 yuan; by 1980, it had jumped to 38.36 million yuan, a 3,836-fold increase. Sideline production in the same period leaped from 5,000 yuan to 10.59 million, a 2,118-fold increase. From 1978 to 1980, crop yield declined by a big margin. Total grain output dropped from 15 million kilogrammes to 9.7 million, a decrease of 36.4 percent. (The per-mu yield had decreased from 963 kilogrammes to 632 kilogrammes, 34.3 percent less.) In addition, both the total and per-mu yield of cotton and rape were also lower. Malu Commune is well-known throughout China for its high yields. Therefore, this warrants our attention. BRIEFS

GRAIN, OIL TRANSPORT--On the basis of the retention of profits last year, grain and oil transport enterprises in Sichuan Province have adopted the method of assuming responsibility for submitting profits to the state for the whole year. By the end of August, they had submitted fixed profits of 2.57 million yuan to the state and overfulfilled their quota for submitting profits for the whole year to the state by 51 percent 4 months ahead of schedule. The amount of profits submitted in this period was 77.9 percent more than in the corresponding period last year. [Chengdu Sichuan Provincial Service in Mandarin 0030 GMT 23 Sep 82]

MIANYANG PREFECTURE PADDY RICE--After reaping a big bumper harvest of spring-harvested crops, Mianyang Prefecture has also reaped a bumper harvest of paddy rice. The per mu yield of the 4.79 million mu of paddy rice is 890 jin. The prefecture's total output and per mu yield of paddy rice are 10 percent more than last year and exceed the previous highest levels. The number of peasants in the prefecture is some 11 million. The per mu yield of the 3.2 million mu of hybrid rice in the prefecture this year is 988 jin. Total output of hybrid rice accounts for 44 percent of the total output of paddy rice. MINISTRY MEETING HELD ON DIVERTING WATER

SK250731 Tianjin City Service in Mandarin 0030 GMT 25 Sep 82

[Excerpts] According to TIANJIN RIBAO, acting on a State Council instruction, the Ministry of Water Conservancy and Power has held a meeting this month from the 22d to the 24th to discuss and make arrangements for diverting Huanghe River water to Tianjin again this winter. The amount of water to be diverted to Tianjin this winter will not be less than that of last year. People in our city will be able once again to use river water diverted into our city from a thousand li away by people in Shandong, Henan and Hebei.

From mid-October to mid-January next year, water will be diverted into our city from Weishan Cistern in Liaocheng Prefecture, Shandong Province, and (Panzhuanggan) pool in Dezhou Prefecture. Before that, beginning 1 October water will be drawn off from a Yuecheng reservoir and be diverted into Tianjin through the Zhanghe and Weihe rivers and the southern channel.

The CPC Central Committee and State Council have shown great concern about the water shortage in Tianjin and instructed the Ministry of Water Conservancy and Power to make arrangements for diverting water from the Huanghe River and Yuecheng reservoir in good time. At its meetings in Tianjin, the Ministry of Water Conservancy and Power worked out specific plans for the time, amount of water and management measures regarding the diversion of water.

Li Boning, vice minister of water conservancy and power, presided at the meeting. While the meeting was in session, leading comrades of the municipal CPC Committee and government including Chen Weida, Li Ruihuan, Wu Zhen, Zhao Jun and Liu Jinfeng went to the meeting place to offer their regards to the meeting participants.

BRIEFS

YELLOW RIVER WATER DIVERTED--Tianjin, 27 Sep (XINHUA)--Yellow River water will be again diverted this winter to China's third largest city--Tianjin which is suffering from a chronic water shortage, according to a recent State Council decision. The first diversion was concluded in January and a total of 450 million cubic meters of water was diverted from the Yellow River last winter. And then rainfall during the summer helped ease the shortage temporarily. However, the city now has a total supply of only 40 million cubic meters, which will last to the end of October. The State Council decision says another 450 million or 500 million cubic meters will have to be diverted from the Yellow River and the Yuecheng reservoir in the upper reaches of the Hai He in Hebei Province in order to avert a shortage this winter. Shandong, Hebei and Henan provincial leaders, plus Tianjin officials, all of them involved in the first water diversion project, recently met in the city to discuss implementation of the State Council decision. BRIEFS

CHEMICAL FERTILIZER PLANT--Urumqi, 17 Sep (XINHUA)--Construction of the largest chemical fertilizer plant in Xinjiang, a major one in China to be equipped with imported installations, is in full swing, according to the Regional Chemical Industry Department. Located in Miquan County near the regional capital of Urumqi, the modern plant is scheduled to be completed and put into operation in 1985. The plant will use residual oil as raw material and produce annually 520,000 tons of urea. Major equipment for the plant is imported from Japan and West Germany. Construction began on the plant in 1980. Now 58 pieces of equipment, including a methanol washing tower, have been installed, and 27,000 meters of pipes laid. More than 4,000 technicians and workers have been sent by the state from Sichuan and Gansu provinces and other parts of Xinjiang to the construction site to help build the plant. [Text] [OW231301 Beijing XINHUA in English 1233 GMT 17 Sep 82]

EDIBLE OIL SUPPLY--In accordance with the decision made by the State Planning Commission and State Economic Commission at a joint meeting and with the circular of the ministries of commerce and finance, Xinjiang Region decided to supply every commodity grain consumer with an additional 2 jin of sunflower oil besides 5 liang of edible oil as a measure to celebrate the National Day and the (Guerbang) festival. In response to this decision, the regional Grain Department and Financial Department have already issued a circular accordingly. [Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 28 Sep 82]

MEETING DISCUSSES AGRICULTURAL DEVELOPMENT

HK280715 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 25 Sep 82

[Summary] The Yunnan Provincial Agronomist Institute, together with the Provincial Economic Research Institute and the Provincial Agricultural Economic Institute, recently held a joint discussion meeting in Kunming on the strategic problem of agricultural development in Yunnan. The meeting took the party's general objective as the guideline and analyzed the existing problems in Yunnan's agriculture. The participants held: "Proceeding from the basic conditions of this province and working out an agricultural development strategy which conforms with the specific conditions of this province is very important and necessary. The reason why agriculture in this province is backward and the agricultural environment is damaged lies in the fact that we have not fully realized the basic role of agriculture in the national economy. In developing agriculture, we once maintained the erroneous guideline of putting lopsided stress on major areas, immediate interests and grain production while neglecting mountainous areas, long-term interests, forestry and animal husbandry." "All this must get close attention."

The participants unanimously held that "if we want Yunnan to become rich, efforts must be made to develop the mountain areas." They said that Yunnan "is a province where mountainous areas account for 90 percent of the total areas. This determines that agriculture is always the foundation for the whole economy in this province and must be strengthened. The province's economic development strategy must give prominence to agriculture, especially to agricultural development in mountainous areas."

TITLE: "Studies on High Lysine Maize With Hard Endosperm"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 4, 20 Aug 82 pp 1-6

TEXT OF ENGLISH ABSTRACT: In the course of converting opaque-2-gene into different background of maize inbreds, we found in some of the derivative lines semi-hard kernels were invariably higher in grain density (i.e. weight/volume) than the ordinary opagues. Both of the kernel types were proved to be homozygous O-2, as shown by their higher lysine content than the dents. The highest level of lysine per kernel ever obtained in one of the semi-hard O-2 inbred was 0.6 percent (see Table 1.) To develop hard endosperm O-2 lines a common source of Mexican Yellow Hard O-2 population obtained from CIMMYT was used as donor parent in crossing with 3 typical O-2 inbreds. The hard endosperm kernels derived from S_1 through S_4 generation were shown to be slightly higher than or nearly equal to the donor parent in lysine content of the kernel. This was also true for lysine/protein ratio and all the other amino acids except glutamic acid, leucine, arginine, and histidine which showed some variation among the combinations (refer to Table 2.) For immediate commercial

[continuation of ZHONGGUO NONGYE KEXUE No 4, 1982 pp 1-6]

use, we have developed a few opaque-2 hybrids with soft and semi-hard endosperm. The physical and chemical properties of different kernel types of these hybrids and their yield performance were compared with their inbred parents (Table 4.) The data presented here are to be completed further more.

TITLE: "Effects of Rice Male Sterile Cytoplasm on Major Characters of F_1 Generation"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese
No 4, 20 Aug 82 pp 7-13

TEXT OF ENGLISH ABSTRACT: Thirteen male-sterile lines of heterocytoplasm-homokaryon and their maintainer lines were mated to 2-restorer lines. Preliminary result showed that most of the F_1 generation of sterile cytoplasm had positive correlation on spikelet per plant and total grains per spikelet, negative correlation on setting percentage and weight of 1,000-grains, and no relation on plant height, growth duration,and resistance to rice blast and bacterial blight with the F_1 of their corresponding maintainers. The comparison of the F_1 of sterile cytoplasm in some of the wild rice aborted pollen (WA) and Chinsurah Boro II, which have been widely used in China's rice production, to the F_1 of their maintainers showed an insignificant difference in the following principal traits: grain yield per plant, spikelet per plant, total grains per spikelet, filled grains per spikelet, fertility, weight of 1,000-grain, plant height, growth duration, and resistance to rice blast and bacterial blight. The effects of sterile cytoplasm on the F_1 included not only those on the sterility and cytoplasm but also those on the combination of karyons concerned. The best cytoplasm for production must be selected from the correct combinations by a series of trials so that the influence of sterility on the F_1 generation can be avoided.

ORG: All of Laboratory of Wheat Varieties, Nanjing Agricultural College, Nanjing

TITLE: "A Preliminary Study on the Hereditary Variations of Yield Components and Plant Height of High-yielding Wheat Varieties Grown in the Lower Yangtse Valley"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTRA SINICA] in Chinese
No 4, 20 Aug 82 pp 13-19

TEXT OF ENGLISH ABSTRACT: Seven high-yielding varieties of wheat (Triticum aestivum L.) grown in the lower Yangze Valley were used in this study to investigate the hereditary variations of 4 yield component characters and plant height. Four row plot with 4 replications in a dibble seeding were studied to determine the genetic variation coefficients (GCV), broadsense hereditabilities, relative genetic advances (GS'), genotypic correlations, and selection indexes. The broadsense hereditability estimates are high for plant height and number of grains per spike, moderate for spikes per plant, and low for weight of 1,000 kernels, and grain yield per plant. The GCV are higher for spikes per plant, moderate for the number of grains per spike, and low for plant height. Since the hereditability estimates and GCV for spikes per plant and the number of grains per spike were higher, single plant selection on these two characters from the 7 varietal populations would be effectual.

[continuation of ZHONGGUO NONGYE KEXUE No 4, 1982 pp 13-19]

The magnitude of relative genetic advance predicated by the population of 7 wheat varieties showed that the spikes per plant had higher GS', number of grains per spike and grain yield per plant had median GS', the weight of 1,000 kernels and plant height had lower GS'. The number of grains per spike was positively and significantly correlated with grain yield per plant. Weight of 1,000 kernels was negatively and significantly correlated with the spikes per plant. The genotypic and phenotypic variances and covariances entering into the computation of the correlations were used to illustrate the construction of selection indexes in wheat. Various selection indexes were constructed and the expected genetic advance from the use of each was determined. The relative efficiency from the use of the various selection indexes compared with selection for single plant grain yield alone. The efficiency of selection index for single plant yield with single correlated character was not high enough, but with two or more characters included the efficiency was well raised. When a selection index includes the single plant yield itself and other correlated characters, its efficiency is better than that whithout the single plant yield.

ORG: Associate Research Group for Agroclimatological Study of Cropping Systems in South China

TITLE: "Regionalization of Cropping Systems in Rice-growing Regions in South China"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 4, 20 Aug 82 pp 35-42

TEXT OF ENGLISH ABSTRACT: In this study 2 main factors, agroclimate and topography, are combined to elucidate the geographical distribution of cropping systems existing in the southern provinces of China. The meteoroecological models are used for evaluating the rice duration in different cropping systems. Climate guarantee probability (CGP) is calculated by the following formula: $CGP = \frac{\text{rice growing season}}{\text{rice duration}}$ which makes clear the availability of climatic condition to certain cropping systems in southern provinces. According to climatic and topographic conditions, the southern part of China is divided into 3 agroclimatic zones, i.e. (1) double and single cropping zone; (2) double and triple cropping zone; (3) triple and double cropping zone. In these zones, 9 agroclimatic regions and 23 sub-regions are further separated. Climatoecological analyses are made for each zone and region.

TITLE: "Environmental Effects of Plastic Film for Cotton Field Covering"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 4, 20 Aug 82 pp 43-50

TEXT OF ENGLISH ABSTRACT: The transparent polyethylene films for cotton field covering produce various effects on the environment. The main effects are decreasing the consumption of the soil heat while increasing the accumulated temperature in the tilth layer and having a compensative effect on the accumulated air temperature. All these contribute to the normal growth and development of cotton during the growing season even under lower temperatures. Therefore, it is suggested that in the first place, the use of the accumulated soil temperature in the tilth layer as an thermal index of the heat necessary for the cotton during its developmental stages may approach more closely the actual state of heat existing in soil. Secondly, the main role played by the plastic film in improving the soil moisture and

[continuation of ZHONGGUO NONGYE KEXUE No 4, 1982 pp 43-50]

heat results in a series of changes to the environment chemically, physically, and biologically. The plants can develop its yield potential to a maximum under the relatively stable growing conditions recognized as the relatively stable effect. Thirdly, thanks to the comprehenisve effects of plastic films such as increasing the total heat in the field soil, promoting the efficiency of water use from soil, adding the supply of carbon,and letting down more sunlight to the soil surface, improving the solar light utilizing efficiency and significant yield increase; the lint yield increase averages 40-60 jin/mu for the irrigated fields and 30-50 jin/mu for the nonirrigated fields.

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTRA SINICA] in Chinese No 4, 20 Aug 82 pp 51-57

TEXT OF ENGLISH ABSTRACT: The experiment has been conducted for 5 years. The fundamental rules and technique of high yield (1000 catties of raw fiber per mu) in jute can be summarized as follows: An effective density of 15,000-16,000 plants per mu and the production of 14-15 g dry fiber per plant at the harvest stage appear to be crucial problems of high yield in jute. The main techniques of high yield in jute culture are as follows: (1) Choose fertile soil under proper irrigation condition; (2) Use prolific varieties of jute and maintain their growing stage up to 150 days; (3) Apply more manure fertilizer so as to increase the weight per plant; (4) Ensure suitable plant density to get more effective plants (planting density set at 20,000 plants/mu); (5) Prevent lodging for the sake of promoting the development of fiber.

TITLE: "Experiments on Seed Vigor of Some Vegetable Crops"

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 4, 20 Aug 82 pp 58-64

TEXT OF ENGLISH ABSTRACT: Various methods to test seed vigor of bean, Chinese cabbage, and radish were examined including germination speed, root elongation, dry weight, TTC conductivity, fluorescence, and ATP. All of them showed various degrees of relation to their field performance such as seedling establishment and its growth rate, i.e. the stronger the seed vigor the more uniform the seedling stand. A pronounced effect of seed vigor on field product was shown in the cabbage. A series of experiments have indicated that both the germination speed and root elongation are more correct, reliable, and convenient criteria than the others; the dry weight (to measure the consumption of stored foods in seeds,) though also corrent in itself is not so convenient because it is time consuming; the ATP is correct and rapid and

[continuation of ZHONGGUO NONGYE KEXUE No 4, 1982 pp 58-64]

may possibly be used in practice in the future. Because of the complexity of the factors influencing seed vigor and the wide variation in field conditions, the authors have considered that no one test is likely to serve best for all crops and, therefore, tests will probably be on a crop-by-crop basis, and even with one crop a combination of several methods may be preferable in some cases to a single one.

SOURCE: Beijing ZHONGGUO NONGYE KEXUE [SCIENTIA AGRICULTURA SINICA] in Chinese No 4, 20 Aug 82 pp 65-73

TEXT OF ENGLISH ABSTRACT: Take-all of wheat caused by Gaeumannomces graminis var. tritici was reported in our country round about 1952. We have studied all aspects of this disease and its pathogen for 13 years (1969-1982). The typical symptoms of the take-all in different stages of wheat development are described. Black root, black foot (the basal stem), and white head are the principal characteristics for the diagnosis of this disease in the field. The morphological characteristics of the pathogenic fungus, both the vegetative and the sexual stages, are described. The infections of hypae and ascospores in nature, the isolation and cultural techniques of the pathogen together with its infection, parasitism, temperature-tolerance, distribution in soil, and survival-time have been studied also. Besides,

[continuation of ZHONGGUO NONGYE KEXUE No 4, 1982 pp 65-73]

the take-all decline phenomenon and the integrated control, including rotation, supplementation of phosphorus fertilizer, tolerant varieties, fungicides, and so on, have been infestigated and studied.

TITLE: "A Preliminary Study on the Silt Carrying Capacity of the Water System of Dongting Lake"

SOURCE: Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 4, Jul-Aug 82 pp 48-56

TEXT OF ENGLISH ABSTRACT: The annual average of the silt carrying capacity of the water system of Dongting Lake is about 40.593 million tons. The water area of the lake is being gradually reduced due to the serious condition of silt deposit. Dongting Lake, originally the largest freshwater lake of China, is being downgraded to the second place behind Poyang Lake in the matter of size. The trend of the quantity of silt carried by Dongting Lake is rising steadily. In the 70's, it almost doubled that of the 50's. A comprehensive harnessing of small watersheds is the fundamental measure for controlling the silt carrying capacity of the lake.

TITLE: "Method of Evaluating the Economic Benefit of Field Protected Forests"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 8, 23 Aug 82 pp 26-32

ABSTRACT: The major objective of protective forest belts is to protect the fields, which are materials of agricultural production. The goal of the belts is to improve the ecological environment of agriculture so as to increase production. The economic benefit of the belts include the increase of agricultural production and the quantity of forest products of the belts. The benefit increases with the formation, coverage, and density of the forests. Thus, the belt is a comprehensive system of complex and multiple functions and when its economic benefit is calculated, considerations must be given to the following: (1) The yield increase of the unit land area; (2) The cost reduction of unit agricultural products; (2) The unit yield increase of fields in a renewal cycle of the forest belt; (3) Other benefits, such as the losses from wind and sand erosion damages prevented by the forest belt. On the other hand the resources and labor consumed by the protective belt must also be taken into considaration. This cost of constructing and managing the forest belt must be distributed from the various benefits, while differences in the species of trees, the structure of the belt, and the technique of pruning, logging, etc. also influence the economic benefits. Equations for calculating all these factors are introduced.

TITLE: "Several Problems in the Development of the Work of Cost Computation of Agricultural Products"

SOURCE: Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 8, 23 Aug 82 pp 50-55

ABSTRACT: Cost computation of agricultural products is an important measure of monitoring and controlling production expenditure and a comprehensive index for evaluating the economic benefit of agricultural production. In the past 2 years, the work of the majority of the cost computation test points has been satisfactory. Under the natural disaster condition of 1980, the grain production of 6 test points remained 636,781 jin, an increase of 0.95 percent over the high yield year of 1979, to demonstrate the effect of the work in promoting yield increase. In the opinion of the author, the following problems still exist, however: (1) The definition of cost of agricultural products; (2) The contents of calculation; (3) The calculation of labor cost; (4) The distribution of labor and materials in the cost; (5) relationship between the major and the auxiliary products in the cost; (6) A cost computation method to suit the responsibility system. Details of these problems are expounded.

CALL FOR ECONOMIC EFFICIENCY IN ENTERPRISE CONSOLIDATION

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 7, 1982 pp 2-3

[Commentary: "Special Commentary on Improving Economic Efficiency in Enterprise Consolidation"]

[Text] Early this year, the party Central Committee and the State Council passed a resolution to carry out an overall consolidation of industrial enterprises. Premier Zhao Ziyang made a speech to the All-China Industry and Communications Conference and placed emphasis on improved economic efficiency as the core of enterprise consolidation. The resolution passed by the party Central Committee and the State Council is perfectly suitable for state farms and land reclamation enterprises. The former Ministry of State Farms and Land Reclamation discussed the issue of consolidating the state farms and land reclamation enterprises at a national conference for the department and bureau chiefs in charge of state farms and land reclamation in March. After the conference, the state farms and land reclamation departments of all provinces, municipalities and autonomous regions issued notices on enterprise consolidation. After the organizational restructuring was generally settled, the General Bureau of the State Farms and Land Reclamation of the Animal Husbandry and Fishery Ministry of Agriculture [newly established], immediately decided that within the next 2 or 3 years the cadres of the organization should be assigned in groups and at different times to participate in the work of enterprise consolidation. This year, four workgroups have been formed and sent to Heilongjiang, Guangdong, Tianjin and Jiangsu reclamation areas to conduct pilot projects and gain experience in enterprise consolidation (including farm, factory and agriculture, industry and commerce combined enterprises).

Since the smashing of the "gang of four," the work of enterprise consolidation in State farms and land reclamation has been carried out several times and has achieved varying degrees of success. From late 1977 to early 1978, the state Council has convened a national state farm work conference and recommended that state farms be consolidated, especially the leading bodies, the staff and workers and the management. At that time, the state farms had serious problems because of the 10 years of chaos. The leadership groups were not skillful, the staff and workers were lax and enterprise management was confusing. After the conference, all levels of state farms and land reclamation departments had carried out, under the leadership of the local party committees and government, a great amount of work in running the state farms, enabling them to gain rapid preliminary progress in production and management. In 1979, China's gross value of industrial and agricultural output, the total output of major agricultural products and the amount turned over to the state under the state farms and land reclamation system all reached new historic levels. Because the state had raised the purchase price for agricultural products, and implemented a financial payment system [a system of payment partly in kind and partly in cash] and a production responsibility system for the state farms and land reclamation enterprises, the management and administration were thereby improved. As a result, a 10-year history of deficit was ended through the realization of a profit of 520 million yuan this year. Furthermore, despite an increased expenditure of over 600 million yuan in 1980, there still were profits of 650 million yuan. In 1981, the Heilongjiang reclamation area suffered especially heavy flooding and drought with great reductions of production, thereby turning the previous year's profits of over 400 million yuan into a deficit of over 300 million yuan. However, by the arduous struggle and fortitude of the broad staff and workers of the state farms and land reclamation system, China still made a profit of 200 million yuan. The number of provinces that had made profits had increased from 18 in 1980 to 25 in 1981. The Jiangsu state farms and land reclamation system also reached the goal in which every farm and factory made a profit.

Nonetheless, we must clearly understand that the production and management standard in the state farms and land reclamation enterprises still are very low and that there are many obvious deficiencies. For example, there were four provinces, municipalities and autonomous regions which suffered losses in 1981. Thirty percent out of the total number of farms throughout the country still suffered losses, with a gross deficit totaling over 400 million yuan. Also in 1981, China's industry netted a profit of about 500 million yuan, but its agriculture suffered over 300 million yuan in losses. This was especially true of animal husbandry enterprises; with the exception of a small number of provincial and regional farms, the majority of provincial and regional farms suffered losses. In terms of the use effect of capital, the output value realized in each 100 yuan of fixed assets was 105.3 yuan in 1979. It was 95.9 yuan in 1981, a decrease of 9.4 yuan. Also in 1979, the output value realized in each 100 yuan of liquid assets was 168.9 yuan, while it was 147.9 yuan in 1980, a decrease of 21 yuan. In 1979, each 100 yuan of fixed assets realized a profit of 5.1 yuan, while it was 7.3 yuan in 1980. For each 100 yuan of circulating capital there were profits of 8.2 yuan in 1979 and 11.3 yuan in 1980. The rate of profit on capital was 3.2 percent in 1979 and 4.5 percent in 1980. Although the capital efficiency was higher in 1980 than in 1979, overall it was still very low. (For 1981 was plagued by natural disasters, and other nonmeasurable factors, so no statistics are given.)

There are a number of reasons for these conditions. We are in the midst of enterprise consolidation and must make conscientious analysis, seeking truth from the facts, learning from past lessons and experiences, take properly directed actions and improve economic efficiency.

The prerequisite for improving economic efficiency is to improve production levels. Economic efficiency can only be improved through production increases, a greater variety of products and an improved labor productivity. Of course, production must be arranged according to the state plan and to market needs. If there is blind production or disregard of the state plan and market needs, even though there may be a great variety of goods produced this will create enormous stockpiles and result in less economic efficiency. Therefore, production developments must go hand in hand with improved economic efficiency.

During this readjustment period, in order to raise the standard of productivity in state farms and land reclamation enterprises, we must focus on content as primary and expansion as secondary and thoroughly and resolutely carry out this policy. According to studies of 15 land reclamation areas, in 1981, the 41 million yuan invested for capital construction was not used in accordance with the state plan. Some areas used the fund for capital construction as production cost, some used up that year's profits and self-owned circulating fund, while some used up or overspent the responsibility system cash surplus or the funds allotted for making changes. If such conditions are not corrected and if capital construction continues to grow this will seriously affect, the implementation of the readjustment policy. In agriculture it will affect our ability to concentrate our forces on increasing yield per unit area now under cultivation; in industry there will be adverse effect on tapping potential, innovation and reform in enterprises currently underway. In the process of implementing comprehensive management of agriculture, industry and commerce, it is necessary to actively develop processing industries which utilize farm product as raw materials. However, it is first necessary to make improvements in agriculture. If agriculture is not improved there will be no solid foundation and the processing industries will be like "cooking a meal without rice" and suffering economic deficiency.

In addition to becoming closely involved with improving production in order to lay a solid foundation for improving economic efficiency, it is necessary to improve management. In recent years, we have implemented financial responsibility systems as well as various forms of production responsibility systems. These have been very successful in strengthening economic accounting, but there are still many gaps in our enterprise management work. Recent investigations of financial and accounting records and materials concerning illegal activities in economic affairs show that the problems are quite serious. According to incomplete statistics from 15 land reclamation areas, 120 million yuan was used in violation of financial and accounting rules, with 18.3 percent of indiscriminate use of the capital, 34.2 percent of unscheduled construction, 16.7 percent of concealing production and reporting less profit, and 7.5 percent of embezzlement and theft, speculation and profiteering. There also were feasting and gift-giving, free spending and waste, using public funds for personal gain, taking public property for personal use and abusing the issuance of bonuses and subsidies. Moreover, because of laxness in the system it was generally not possible to assign responsibility to anyone for the loss of money and property or for the waste and abuses. Therefore, all leadership levels must pay attention to these problems, combining investigation of financial and accounting violations with tackling the criminal economic activities, and making it an important part of the enterprise consolidation efforts. During enterprise consolidation, the truth which has been exposed should be used as a lesson to educate the broad staff and workers for the good of the country and the good of our enterprises, protecting state finances and property from damage and loss. The exposé should also be used as a lesson to promote our superior traditions of an arduous struggle against corruption, never becoming tainted and wage a resolute fight against all activities which violate state financial and economic regulations or damage and misappropriate state funds or property. At the same time, all regulations must be strengthened and rigidly enforced to build the state farms into socialist new enterprises having high levels of both material as well as spiritual civilizations.

According to the demands of the party Central Committee, enterprise consolidation is to be all-encompassing. Consolidation should be done well in "three constructions," namely: gradually construct a democratically centralized leadership system, gradually build rank and file staff and workers that are both "red" and expert, and gradually construct a management system that is both scientific and spiritually civilized in its approach. We should do well to meet the "six demands," namely: correct consideration of the three constructions, superior product quality, high economic efficiency, good labor discipline, quality cultural production and good political work. Our state farms and land reclamation enterprises ought to follow these standards in evaluating each enterprise. If the results do not meet the standards even after consolidation, we must further study so that we do not lower our standards even the slightest.

All levels of state farms and land reclamation departments must classify and prioritize their state farms and land reclamation enterprises under its jurisdiction. For instance, which enterprise should be consolidated first and which enterprise later, making an all-round, comprehensive plan to consolidate step-by-step. This year, there first ought to be consolidation of those "old, big problem" units which have made slow progress in production and management and suffered huge financial losses. Competent work teams should be sent to help the enterprise quickly change conditions. The starting point for consolidation and the techniques to be used for consolidating each enterprise depend on the particular circumstances involved. Some should start with the leadership groups that are engaged in consolidation, some should start with adjustments in management and policy, some should start with strengthening of the production responsibility system, and some should start with consolidation of financial and economic rules and regulations or with an investigation of and an attack upon illegal activities in the economic affairs. In general, the actions should suit the needs rather than to impose arbitrary uniformity. Leadership cadres must personally participate in enterprise consolidation. They must be in the front lines in person and grasp well first-hand information in order to obtain direct experience and promote these consolidating efforts.

The process of enterprise consolidation must strictly adhere to all points of the party plans and policies. Under the leadership of the local party committee and local government there must be complete reliance upon the broad staff and workers to carry out consciencious study and investigations, make complete and realistic analyses of everything and arrive at realistic, and not subjective and partial conclusions, partially avoiding all extremes in their actions.

In consolidation, we should uphold everything that is correct, and correct everything that is wrong. Some issues must be conscientiously studied and researched, made clear of what is correct and incorrect through discussions with staff and workers and approved by the upper level leadership before they can be strictly carried out. For example, in implementing production responsibility system, a question of how to carry out the principle of distribution according to work must be correctly handled according to the relationship between the interests of the state, the enterprise and the individual. There still is the issue of how to develop an economy based on a collective ownership system while carrying out the principle of exchange for equal value. Another issue would be how to promote the staff's and workers' family sideline occupations with assurance that these sideline occupations will not adversely affect the workers completing their primary jobs and in turn jeopardizing the state interests.

Enterprise consolidation will also have social bearing as a result of management profit and loss. In order to accurately calculate enterprise management conditions, the various expenses which should not be shouldered by the enterprises should be itemized individually and specifically. Separate calculations should be made so that these expenses are not included in the profits and losses, and certainly not figured in the production costs. Only by taking out from the enterprise expenditure the costs which the enterprise does not bear can we really show the management and administrative levels of the enterprises.

At the same time that all the state farms and land reclamation departments are conducting test work in enterprise consolidation, they also must make proper arrangements for their regular work. This year, some land reclamation areas suffered many difficulties because of adverse weather and various natural disasters. There also were many labor problems. We must mobilize the broad staff and workers to promote a strong sense of responsibility and strive in all possible ways to fulfill or overfulfill this year's production management plan.

RURAL FAIRS, MARKETS 'FLOURISHING'

Beijing ZHONGGUO NONGMIN BAO in Chinese 15 Aug 82 p 1

[Article: "Rural Country Fair Trade Flourishes in Wake of Third Plenary Session; Volume of Business of the More Than 40,000 Rural Country Fairs in the Country Amounted to More than 20 Billion Yuan In 1981"]

[Text] In the wake of the Third Plenary Session [of the 11th Party Central Committee], agricultural production has developed, city and countryside trade has become lively, and rural country fairs have increased concomitantly. Today, rural country fairs in the country number more than 43,000, of which somewhat more than 1,000 have been added since last year. In 1981, the volume of business done at rural country fairs amounted to more than 20 billion yuan.

During the first half of this year, commodities sent to market at rural country fairs continued to increase, and both purchases and sales were lively. Statistics from 206 representative rural country fairs in China showed a 440 million yuan volume of business for the first half of this year, a 23.4 percent increase over the same period last year. The volume of transactions in major commodities was also up over the same period last year, including grain by 8.4 percent, edible vegetable oil by 32 percent, pork by 16 percent, hen's eggs by 32 percent, vegetables by 19 percent, tobacco by 25 percent, draft animals by 16 percent, and shoats by 9 percent. Household furniture, civilian construction materials, and iron and wood manufactures also increased greatly. A particularly large amount of small farm implements went to markets, and trading was brisk. Statistics from 17 country fairs in Sichuan showed that as compared with the same period last year, transactions between January and May this year increased 1.5 fold for grain sunning mats, 39 percent for large wicker baskets, 28 percent for carrying poles, 70 percent for winnowing baskets, and 41 percent for night-soil buckets. In Yanbei Prefecture in Shanxi Province, volume of transactions in the means of production during the first half of the year increased 2.4 fold over the same period last year. Manure baskets and hoes, which had formerly been hard to find in markets, could now be bought. As a convenience to commune member's, Ningxia established special small farm tool markets in fairly large fairs. During the first half of the year, the Chengguan Fair in Wuzhong County made sales of 293 hand tractors.

During the first half of this year, the amount of small daily use commodities going to markets also increased. Statistics from 206 fairs in the country show more than double the volume of transactions in industrial products used in daily life during the first half of this year as compared with the same period last year. In Hebei Province's rural fairs, small goods used in daily life such as sundries, metal fittings [nails, wires, hinges, bolts, locks, etc], small knit goods, small toys, and small plastic items enjoyed a 1.4 fold increase in volume of transactions over the same period last year. In Zhejiang Province, volume of transactions in small items used in daily life during the second quarter almost doubled over the same period last year. Prices of most of these small articles were close to or somewhat lower than the state-run retail price, and buyers were fairly numerous. During the first half of this year, prices of goods at rural country fairs were stable. Except for the month of January when prices rose by an average 2.3 percent over the same period last year as a result of the new year and the lunar new year, in all other months the rate of price increase was around 1 percent. Prices were 1.9 percent lower at the end of June than at the end of May. Decline occurred in the price of grain, tobacco, sesame, pork, poultry eggs, vegetables, nuts and fruit, sundries used in daily life, firewood, the agricultural means of production, and livestock.

METHOD FOR FIGURING ECONOMIC BENEFITS OF FARMLAND IRRIGATION OUTLINED

Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 3, 1982
pp 39-40

[Article by Sun Hongming [1327 3163 2494]: "Exploration of Methods of Figuring Farmland Irrigation Economic Results"]

[Text] No common conclusion has yet been reached on methods for calculating economic results from use of water resources for farmland irrigation in China. I believe that the economic benefits of water in farmland irrigation should rest on the common principle of the results of production in a socialist society, namely, that the results of socialist production should be to satisfy increase in the people's material and cultural standards of living, and that the most important element in assuring this increase is improvement in the social labor productivity rate. This reflects the relationship between objective cause and effect between society's expenditure of labor and its economic results. Consequently, it is necessary to use, both rationally and highly effectively, production resources and natural resources to increase the results of social production. In this way increases in the social labor productivity rate and improvement in results of all social production, or of individual sectors of production, constitutes a criterion for judging economic results from the use of water resources.

In irrigation, water is the main element in improving the soil's economic fertility. It provides optimum possibilities for assuring consistently high crop yields. Irrigation acts principally to improve the soil, and water also become an intermediate "product" in soil improvement, but not a final product. Thus, water further becomes a basic means of production in irrigation agriculture. To judge the economic effectiveness of irrigation water (or, say, the economic benefit of that portion of water resources used in irrigation) according to the results of agricultural production from the watered area, I believe is methodologically desirable. Therefore, the total benefit per unit of area of irrigated farmland minus the total benefit per unit of area of dryland, under similar conditions (climate, soil, fertility, seeds, closeness, plant protection, tools, and field care), constitutes the economic benefit of irrigation, which is the economic benefit of water in agricultural production. Of course, one may also calculate the economic benefits derived from the use of irrigation on the basis of the difference between the total output value, gross earnings, net income (profit) and value of yields per unit of area provided by watered land and the total output value, gross earnings, net income (profit), and output value per unit of area from dryland. As compared with economic benefits in increased work efficiency resulting from technological innovation in industry, this method of calculation is both simple and easy to calculate.

Results derived from the use of this method to figure the economic benefits of irrigation in several prefectures of Qinghai Province are provided below:

1. Xiaoxiaqu Irrigation Area. Located in Ping'an County in Qinghai Province, this is an old irrigation area in the Huangshui Basin, which underwent reconstruction in 1963 and now irrigates an effective area of 11,000 mu. Irrigation during the first year following reconstruction produced grain (wheat) yields of 400 jin per unit of area (average value for the irrigation area), which subsequently continued to increase to 600 jin (in 1972), 745 jin (in 1975), and 857 jin (in 1979). Meanwhile, during the same period, under the same conditions, dryland yields of wheat amounted to from 250 to 375 jin per unit of area. Economic benefits should be 400 jin--250 jin = 150 jin, and on to 857--375 jin =482 jin.

2. Xiaozao Irrigation Area. Located in the Wutumeiren Xiaozaohuo region of Geermushi in the Tsaidam Basin, it is an inland river system. Rainfall in the area is scant and hot dry winds are frequent. This irrigation ditch area was built in 1970 to irrigate a 4,200 mu area. Under the same conditions, dryland wheat produced yields of 200 jin per mu, but following irrigation yields became 475 jin per mu (irrigation area average), and a maximum of 1,000 jin per mu. Economic benefits of irrigation were 475 jin--200 jin = 275 jin.

3. The Gandu Commune Irrigation Area in Hualong County. Located along the Huang He where rainfall is fairly good, the irrigation area is 13,000 mu. Under similar conditions, dryland wheat yields were 300 jin per mu. Following irrigation, the average yield for the entire irrigation area was 890 jin per mu (in 1980). Economic benefit was 890 jin--300 jin = 590 jin.

4. Beishanqu Irrigation Area. Located in Menyuan County in Haibei Zhou. Designed to irrigate an area of 53,000 mu, in 1980 it actually irrigated 34,900 mu. It is part of the Datong He Basin where there is a fair amount of rainfall and where dryland yields were 250 jin per mu. Following irrigation yields were 400 jin per mu, the economic benefit being 400 jin--250 jin = 150 jin.

The Huangshui Basin, the Huang He, and the Tsaidam region in the province have long hours of sunshine daily, and the soil is good making them good places for development of agriculture. The actual examples calculated in the foregoing show the following: Water conservancy work holds an important position in Qinghai's agricultural production; its role in increasing agricultural yields is tremendous. Were a low average value of 250 jin per mu used to calculate the overall average increased yield per mu of irrigated land as compared with dry land for the province as a whole, the province's 2.8 million mu of irrigated land could grow an additional 760 million jin of grain each year. This shows that the construction of water conservancy in Qinghai has made a tremendous contribution to increases in agricultural production.

Benefits in increased agricultural production of water resources in other areas differ. Intensified research on the benefits of water resources has real value in guiding future water conservancy construction and the development of agriculture.

NONENGINEERING MEASURES IN FLOOD PREVENTION URGED

Beijing ZHONGGUO SHUILI [Water Conservancy in China] in Chinese No 3, 1982 pp 7-9

[Article by Wang Juemou [3769 0628 5399]: "We Should Stress Nonengineering Measures in Flood Prevention"]

[Text] At present, there are generally two types of flood prevention measures: one type is referred to an engineering type flood prevention measures and the other, nonengineering type flood prevention measures. Included among engineering prevention measures are the construction of water reservoirs, clearing areas for flood retention and storage, dike construction, regulating river channels, opening up of flood diversion channels, and building large pump stations; all the above-mentioned are flood prevention projects. Included among the nonengineering flood prevention measures are flood forecasting and alerts, classification and management of flood areas, flood prevention insurance, and social relief. The popularity of nonengineering measures is due to the large land areas and investment required in engineering measures, especially in large flood prevention projects; some projects even occupy more land than the protected area downstream. Large investments in flood prevention are especially painful for developing countries because they are unable to construct sufficient flood prevention projects in a short period of time. Even in some developed countries, because most projects have been completed on dam sites with better conditions, economic benefits are doubtful from the remaining difficult and high-investment projects with troublesome problems of relocating area inhabitants. Therefore, the nonengineering measures have been more and more stressed with faster growth.

I. Nonengineering Flood Prevention Measures Cooperate With Mother Nature.

Engineering-type flood prevention measures can be regarded as those measures which reshape natural settings; since the natural characteristics of floods are modified by engineering means in order to prevent or reduce flood damage. Nonengineering flood prevention measures are not intended to modify natural flood characteristics; instead, the effects of flood damage are to be relieved in order to reduce the damage; therefore, nonengineering measures can also be called measures cooperating with nature.

Flood forecasting and alerts: Before flooding occurs, forecasts and alerts are transmitted in order that timely urgent measures to avoid flood damage and to hold flood losses to a minimum be taken. Under flood forecasting and alerts, timely measures of flood diversion and storage can be adopted; appropriate flood prevention actions on water reservoirs can be taken; and timely emergency repair of flood prevention facilities and evacuation of area inhabitants can be carried out to cope with the flood. For example, in the case of the floods of July 1981 in the upper reaches of the Yangtze River, at Chongqing Municipality the government took advantage of flood forecasting to order evacuation to safe areas of 220,000 inhabitants as well as moving the industrial plants and governmental organizations along the river banks. Thus, the upheaval of people's lives and property was considerably reduced.

The effect of flood forecasting and alerts is closely related to how accurate and effective the information is. Generally speaking, the higher the forecast accuracy and the earlier it is made, the smaller are the losses caused by the flood. Therefore, we must do our best to improve the technical means of communications and computation in order to enhance reporting accuracy and to extend the effective prediction period.

The classification and management of flood-damage areas: we can base our approach on different flood frequencies and degrees of flood damage to classify flood areas in order to take appropriate measures. In some cases abroad, flood damage areas are classified into three zones: (1) The strictly forbidden zone: no permanent structures are allowed in zones with an average of one flood occurring every 5 years; additions to existing structures are banned. (2) Restricted zone: relatively lower economic-value structures are allowed in zones with an average of 1 flood every 5 to 20 years; these structures should have flood prevention facilities, such as roof platforms and village dikes. (3) Alert zone: structures can be free of restriction in zones with an average of 1 flood for every 20 to 50 years. However, inhabitants in these zones should be alerted; upon receiving flood forecasts or alerts, appropriate actions should be taken.

At present, there are large numbers of inhabitants in most flood zones in China, especially on river banks, in areas of flood diversion and storage, and along river channels downstream from water reservoirs; there are many structures and some are still under expansion. Considerable damage will result if a flood happens. So, it is significant to reduce damage in flood areas by proper classification of flood zones in guidelines or laws with enforcement by management.

Flood prevention insurance: insurance can reduce losses incurred by inhabitants and enterprises in the flood zone; the loss is not paid out all at once but in installments. This can be valuable in stabilizing people's livelihood and social order, as well as in reducing the burdens on the state. For example, during the Sichuan flood in 1981, more than 60,000 yuan of indemnity was paid out by insurance companies to 210 insured households; altogether, 77.28 million yuan of indemnity was paid out to 1,490 commercial and industrial enterprises incurring flood damage.

Additionally, every year inhabitants and enterprises subscribing to flood prevention insurance should pay premiums; thus, they have an awareness of possible disaster. This is what we often said "Be Alert and Overcome Apathy." This can be a relatively effective "mobilization" linking economic benefits. If the amount of insurance premiums can be classified and linked with flood zones, unplanned construction in the flood zone can be effectively restricted. In addition, the purpose of flood prevention insurance is not simple, passive indemnity; more important is the protection from future occurrences. This concept can mobilize more social forces to engage in flood prevention activities and to promote flood prevention.

Social relief: this category serves to mobilize social resources, state resources, or even international resources to reduce flood damage to individuals and collectives in order to restore production as quickly as possible and to reduce damage caused by floods.

China has a relatively rich experience in flood prevention and relief; this demonstrates the superiority of the socialist system, since all area populations unite to extend a helping hand once a disaster strikes; this is self-relief by means of production incomes. The state allocates flood prevention and relief funds for these activities. This is also an important guarantee of China's victory over the years of the flood prevention struggle.

II. Engineering Flood Prevention Measures Should Closely Coordinate With Nonengineering Measures, in order Adequately To Exercise Their Functions.

There are still wide areas in China lacking any engineering flood prevention measures. In these areas, existing flood prevention measures are only nonengineering measures, emergency measures of temporary repair of flood facilities, and evacuation from floods upon receiving flood forecasts and alerts. Even in areas with engineering measures, their implementation relies on close coordination with nonengineering flood prevention measures.

After 32 years of difficult struggle, China has built many dikes, water reservoirs, and flood prevention projects. It has cleared flood retention and storage areas and constructed dikes to increase considerably the flood prevention capability of rivers. However, flood prevention standards are still low. Once there is a very high-water-mark flood, we only can ensure project safety and reduce flood damage by emergency measures of temporary repairs to flood facilities based on flood forecasts and alerts. In Japan, standards of flood prevention designs are not high; generally, concrete dams are designed for large floods which occur once every 100 years; earth and masonry dams are designed to withstand large floods occurring once every 200 years. The Japanese approved standard for floods is an addition of 20 percent to their design standard. However, the Japanese closely empahsized building automated systems, such as hydrological sounding and reporting, as well as communications dispatch, capable within a few minutes, of flood forecasting and alerting together with the corresponding dispatch measures. These nonengineering flood prevention measures can make up for the deficiency of lower standards in construction projects.

The dispatch and operation of flood prevention projects should be coordinated with nonengineering measures in order to gain the maximum economic benefit. For example, in flood prevention dispatch of water reservoirs, the reservoir water may be drained in advance, based on flood forecasting to vacate flood prevention capacity in the reservoir in order to reduce the flood flow when it comes.

Reservoir drainage can be controlled based on flood forecasts in the upper and lower reaches of the reservoir in order to moderate the flood peak downstream for safety's sake. Operations in the zone of flood retention and storage should also be conducted in this way so that flood forecasts and alerts as well as analysis of water situation should be consulted to see whether and when the flood prevention operations should begin, how much flood diversion is necessary, when prevention operations should be suspended, and when the inhabitants in zones of flood retention and storage should be evacuated. Appropriate activities should be taken for the best effects. Otherwise, damage will still occur even with these flood prevention projects.

III. We Must Stress and Strengthen the Buildup of Nonengineering Flood Prevention Measures.

Over a considerably long period, restricted as we are by scientific and technical levels as well as by financial and material resources, we are unable to completely control mother nature; this is so in the case of flood control. Therefore, in the struggle against nature (including combating floods), we should not only study and reform nature, but also pay close attention to studying how to cooperate with nature. In the coming construction of flood prevention projects, except for meeting the requirements of the national economy and the construction of some necessary flood prevention projects, we should pay more attention to the study and reinforcing of nonengineering flood prevention measures by cooperating with nature.

In nonengineering flood prevention measures, some (such as the classification and management of flood-damage zones) require the drafting of rational approaches advanced by water conservancy departments; the state promulgates rules and policies with emphasis on management authority for strict execution. The water conservancy departments should be coordinated with other departments and social circles to execute some measures, such as flood insurance and social relief. China still lacks experience in some measures requiring the trial-and-error approach. However, flood forecasting and alerting measures are relatively established; this is the most important and the greatest effect in nonengineering flood prevention measures. This is also one flood prevention measure with the most rapid advances worldwide.

At present, long-term flood forecasting worldwide is not yet established and cannot be used as the basis of flood prevention measures. At present, we still rely on short-term flood forecasting based on precipitation amounts and water situations in the upper streams. However, the forecasting period is very short in some rainstorm areas and mountains, especially in the medium-sized and small valleys in the case of short-term flood forecasting. Thus, we frequently are unable to meet the requirements of flood prevention measures. In order to extend the effective flood forecasting period, in some countries automation systems were established in key flood prevention areas and at important water conservancy projects; these systems include flood sounding and reporting, communications dispatch, and flood alerts using advanced means of communications, such as ultrashort waves, microwaves and communications satellites (in some cases) to collect information on rainfalls, water and repair acitivites by remote sensing stations, as well as the transmission of forecasting and alarm and dispatch of repair activities.

Since the spacing of hydrology remote sensing stations at present is still unable completely to cover the needs of rainfall information in river valleys, rain-gauging radars have been used in the United States and Japan in principal rainstorm and flood areas. By now, rain-gauging radar can supply data to enable indoor displays or printouts of quantitative rainfall distribution of more than 30,000 square kilometers of valley area; the data are as accurate as having a rainfall station for each 200 square kilometers; the data also indicate the qualitative rainfall distribution over more than 120,000 square kilometers. In recent years, in the United States a satellite cloud atlas was used to estimate the rainfall distribution in a larger area. These techniques play a major role in understanding the variability of rainfall in space and time, in enhancing accuracy in flood forecasting, and in dispatching flood prevention operations. In some countries, these means of communications provide linkages between flood forecasting, automatic control of water conservancy projects, and the automatic flood alert system. In the case of Japan, these automatic flood alert systems have been installed on 107 rivers. Generally, these systems are linked with an electronic computer, which processes this collected data; so the processing of the collected data and forecasting of the dispatch calculation are very rapid, usually only several minutes for the entire process. This not only considerably enhances the effectiveness of flood forecasting, but also improves forecast accuracy.

Flood forecasting accuracy in China advanced rapidly from several points to wide area since the liberation; flood forecasting played a major role during the years of the flood prevention struggle. However, the technical means of flood forecasting is still relatively backward; generally, telephones and telegraphs in the posts and telecommunications system are used to collect water information and dispatch flood prevention activities. Manual work is involved in flood forecasting, dispatch and computation. Usually, 4, 5 or even more hours are required to carry out flood forecasting and process computation. This technique of flood forecasting cannot meet the requirements of flood prevention, especially the requirements of relatively fast flood flows and areas in need of urgent flood prevention activities.

One characteristic of flood prevention in China is that the elevations of areas in the middle and lower streams of major rivers are located below the flood water level of these rivers. Generally speaking, protection against flood relies on more than 160,000 kilometers of dikes and many zones of flood retention and storage. The threat from flooding in these areas is quite high; the safety or flooding of these areas affects China's performance in the national economy. Therefore, the mission of flood prevention is quite important with a long line of flood defense. Secondly, the rainstorm flood has high water levels and its arrival is swift in some key areas of the middle and upper streams of major rivers; this situation is critical in flood prevention characteristics to improve China's flood forecasting and alerting system with planning and priority. For the time being, we still must rely on existing facilities of the posts and telecommunications system to better exploit their potential in flood prevention. Additionally, we should sufficiently utilize microwave trunk lines completed in recent years by the posts and telecommunications system. Our water conservancy departments are unable, or find it unnecessary, to install exclusive trunk lines. However, at the key river sectors of flood prevention in the middle and lower streams of China's major rivers, such as the middle and lower streams of the Yellow River, the sector from Yichang to Hankou of the Yangtze River, the trunk of Huai River, areas of the Yi and Shu Rivers, and the middle and lower streams of the Hai River, the water conservancy departments can build exclusive microwave branch lines at the key aforementioned flood prevention river sectors if the posts and telecommunications system has not considered building microwave networks. Next, in some key flood prevention areas mentioned above, flood sounding and reporting as well as an automatic system of communications dispatch (better yet, rain-guaging radar) should be gradually installed; a flood alerting system should be operated on a trial basis in key areas of flood diversion and storage. In some provinces (municipalities or regions) with the heavy task of flood prevention or with key water reservoirs, trial operation of an automatic system of flood forecasting and communications dispatch should also be started. This work should be included in the long-term plan of water conservancy departments, regarded as an item of capital construction. By spending a certain amount of water conservancy funds to emphasize this work, we can gain the best return of benefits while eliminating damages at minimum costs when compared to funds required for construction facilities.

RURAL ECONOMY REPORTED THRIVING OVER 3 YEAR PERIOD

Beijing ZHONGGUO NONGMIN BAO in Chinese 19 Aug 82 p 1

[Article: "All Around Development of the Country's Farming, Forestry, Animal Husbandry, Sideline Occupations, and Fisheries, and General Increase in Peasant Income; Policies in the Wake of the Third Plenary Session Show Tremendous Power"]

[Text] The correspondent recently learned from the Ministry of Agriculture, Animal Husbandry and Fishery that since the Third Plenary Session of the 11th Party Central Committee, the country's agricultural production has achieved sustained and steady all around growth. This trend of development, which is currently in the ascendant, is such as has rarely been seen since founding of the People's Republic.

The Third Plenary Session of the 11th Party Central Committee convened in December 1978 conscientiously summarized the lessons of experience in agricultural production since the founding of the People's Republic, corrected leftist errors, put forward various rural policies for the present stage, and adopted various major policy measures for hastening development of agriculture. CPC committees and people's governments in all jurisdictions assiduously put into effect an honoring of the self-determination of production teams, institution of agricultural production responsibility systems, readjustment of the rural economic structure and production patterns, development of economic diversification, revival of country fair trade, and increase in procurement prices paid for agricultural products as a series of policy measures to enliven the economy and arouse the enthusiasm of the broad masses of peasants, eight hundred million peasants produced contentedly and diligently.

First was to get all around development of agricultural production. Despite the frequent disasters encountered between 1978 and 1981, gross output value of agriculture annually increased at a rate of 5.6 percent to exceed the average speed of 3.5 percent annual growth between 1953 and 1981, presenting a thriving scene of all around development of farming, forestry, animal husbandry, sideline occupations, and fisheries.

Comparison of major farm product output in 1981 with 1978 shows the following: Grain up by 6.6 percent and for cotton, oil-bearing crops, sugarcane and sugarbeets, increases of 36.9, 95.6, 40.5, and 135.4 percent respectively, all of which were all time highs since founding of the People's Republic. Mulberry silkworm cocoons, tea, tobacco, and such economic crops also showed large increases.

Particularly gladening was that the country's grain output broke through a sustained situation of fluctuation. For a period of time prior to 1978, it had fluctuated for a long time around the somewhat more than 500 billion jin mark, but during the past 3 years, despite increases and decreases, grain output broke the 600 billion jin mark. In 1979 and 1981 output was the highest and second highest since founding of the People's Republic. This year's summer grain crop was up again over last year. Average amount of grain per capita also increased from the somewhat more than 500 jin prior to 1978 to somewhat more than 600 jin. In 1978 China had to import grain, cotton, edible oil, and sugar, Now, however, except for the continued import of some grain needed for readjustment of the structure of agriculture, as a result of great increases in output, cotton and sugar imports have decreased over the years, and in 1981 edible oil was exported rather than imported.

During the past several years livestock industry production has also flourished for a new situation of all around increase. A comparison of 1981 with 1978 shows total national output of pork, beef, and mutton up by 47.2 percent, and a 59.6 percent increase in foriegn exchange earnings resulting from the export of livestock and poultry products and of some processed products. Volume of exports of hog bristles, hog casings, rabbit fur, rabbit meat, honey, feathers, and goat hair were the highest in the world.

For acquatic products, between 1979 and 1981 output of freshwater fish rose 30 percent over 1978 for the greatest consecutive 3 year increase since the 1960's. Rearing of certain traditional marine products is gradually being revived and valuable varieties that can be provided for export such as prawns and scallops have been developed.

Since the Third Plenary Session, annual gross output value of commune and brigade enterprises has averaged a 16 percent speed of incremental increase to become a powerful mainstay in the consolidation and development of the rural collective economy. As a result of readjustment and reorganization, in 1981 the number of enterprises and personnel in them were fewer, yet total earnings still increased by 12 percent over 1980, amounting to 67 billion yuan.

Changes have also been remarkable in the state farm and land reclamation system during the past 3 years. Ever since the Third Plenary Session of the 11th Party Central Committee, state-owned farms have carried out a readjustment, and production has attained all around development. The year 1979 brought an end to the loss situation that had endured for more than 10 years, with profits of 397 million yuan. In 1980 again there were profits of 660 million yuan. For the 2 years, total output of grain (including soybeans) and commodity grain increased by more than 1 billion jin. Industry and agriculture's gross output value increased 5.6 percent. During 1981, 44 percent of the cultivated area in state farm and land reclamation zones sustained disasters, but apart from a decline in output of grain and stud hogs, production by all sectors of the national state farm and land reclamation system rose. Industrial and agricultural gross output value increased 0.2 percent for profits of more than 200 million yuan. In addition, in production a start was made to move away from farming alone into diversified farming, industrial, and commercial activities.

During the past several years a "craze for science" has taken place in rural villages, with peasant enthusiasm for studying science and using science reaching unprecedented heights. Gradually traditional production experiences are gradually being combined with modern science. In rural villages, in order to meet the need for scientific farming, all kinds of organizations for the popularization of science have hurried to organize technical forces to send scientific and technical knowledge and achievements into rural villages. The work of disseminating agricultural science and technology has developed rapidly in rural villages throughout the country. Agricultural education work is also being revived and developed. The CPC Central Committee and leaders at all levels pay close attention to the "investment in intelligence." It may be seen that a new era is arriving in which China's agricultural production and rural construction depends on modern science and technology.

Accompanying implementation of the party's rural policies has been fairly rapid development of the rural commodity economy, and the rural economy has come alive. Commune member private plots have been restored and encouragement and support given household sideline occupations. There has been a liberalization of country fair trade for a revival of traditional rural markets and fairs such as early markets, pre-dawn markets, night markets, night fairs, mountain markets, old style fairs, and horse and donkey markets. Large and medium size cities, including Beijing, have made special efforts to open farm trade markets within their municipal areas in which the lines of goods are complete, numerous varieties of agricultural sideline products are offered, and in which commune and brigade industrial products and native specialties are displayed in large numbers for an expansion of the exchange of goods, to supplement goods not available from state-owned businesses, and to satisfy the needs of the masses in daily life in an unprecedented flourishing of city and country markets. Statistics show the volume of business in country fair trade to have increased 68.6 percent between 1978 and 1980, and in 1981 the volume of trade increased again.

The excellent situation in China's rural villages during the past more than 3 years has been manifested in a concentrated way in a general increase in peasant income and remarkable improvements in standards of living. In 1981 national average per capita income from collective distributions for the agricultural population reached 116.20 yuan, a 31.3 percent increase over the 88.50 yuan of 1978. In 1981 average per capita purchases of consumer goods by rural residents was 117.40 yuan, an 85 percent increase over the 53.90 yuan of 1978.

In places where natural conditions are good and agricultural resources fairly abundant, and in large suburbs and frontier pastoral areas, during the past 3 years some communes and brigades have become wealthy. In 1979 production brigades throughout the country in which commune member average per capita earnings from collective distributions amounted to more than 300 yuan numbered 1,622. In 1980, this increased to 5,569, and in 1981 to 10,943, a 96.5 percent increase over 1980. In addition, substantial turn for the better occurred in a number of brigades and communes that had for long been poverty stricken. In 1980, 72 of the country's 210 impoverished counties in which average per capita distributions had been below 50 yuan for 3 consecutive years broke out of their impoverished state for the first time. Average per capita consumption figures for commune households rose 27.27 percent between 1978 and 1980, and the nature of expenditures also improved. Survey of income and expenditures by more than 18,000 commune member households in 536 counties showed the number of hardship households averaging net per capita annual incomes of less than 100 yuan had fallen from 33 percent in 1978 to 10 percent in 1981.

Between 1978 and 1980 newly built rural housing amounted to 900 million square meters, and in 1981 another 600 million square meters of new housing was built, the amount increasing year by year.

Overall, during the past more than 3 years rural development has been heartening and encouraging. Facts have provided a potent reply to the following issue: The socialist system is genuinely superior. With correct programs, policies, and measures, it is able to stir the enthusiasm of the broad masses. Our socialist endeavors hold great hope.

GREATLY INCREASED GRAIN PROCUREMENT REPORTED

Beijing RENMIN RIBAO in Chinese 11 Aug 82 p 1

[Article: "Number of Anhui Counties Making Sales to the State of 100 Million Jin of Commodity Grain Increases to 40, Amounting to More Than Half the Counties in the Province; Twenty Counties Provide More than 200 Million Jin of Commodity Grain; Institution of a Responsibility System Whereby Production Is Contracted to Households Has Rapidly Transformed a Poverty Stricken and Backward Situation"]

[Text] During the 1981 grain year (from 1 June 1980 until 31 May 1981), the number of counties in the province selling more than 100 million jin of commodity grain to the state rose to 40 from the 22 during the 1977 grain year. This amounted to more than half the total number of counties in the province, twelve of which provided more than 200 million jin of commodity grain. After the 1982 grain year began, enthusiasm for selling surplus grain ran high among the peasants, and everywhere in the province the grain procurement situation was even better than last year.

Among the counties that sold more than 100 million jin of commodity grain to the state, quite a few had developed production only slowly in the past, and had eaten grain provided by the state or grain resold to them. As a result of the disturbance caused by "leftist" ideology in the past, these counties had long been unable to change their poverty stricken and backward situation, and commune member problems in getting enough to eat and to wear had not been solved. After the Third Plenary Session of the 11th Party Central Committee, these counties instituted the contracting of production to individual households and the contracting of work tasks to individual households at a fairly early time. As a result, they made a new beginning fairly quickly, and manifold increases occurred in both grain output and the amount of commodity grain provided the state. Between 1963 and 1977, Chuxian Prefecture had never been able to fulfill its more than 500 million jin state procurement and excess procurement grain quotas, but in the 1981 grain year it provided the state more than 1.36 billion jin of commodity grain. Each of seven counties in the prefecture sold the state more than 100 million jin of grain. Long famous as a poverty stricken county, Fengyang County ate grain resold to it by the state for more than 20 years following liberation, but in the 1981 grain year it sold the state 235 million jin of grain. Formerly, in a year of good harvest, Tianchang County was able to sell the state only 60 or 70 million jin of grain, but in the 1981 grain year it sold the state more than 300 million jin. Huaiyuan County on the banks of the Huai He sold somewhat more than 130 million jin of commodity grain to the state in 1977, but in 1981 this increased to more than 390 million jin, making it the county in the province that sold the most commodity grain to the state.

PROGRESS ON WATER, SOIL CONSERVATION REPORTED

1982 Semi-Annual Status Report

Lanzhou GANSU RIBAO in Chinese 19 Jul 82 p 1

[Text] The province has made very good achievements during the first half of this year in its water and soil conservation activities centering around afforestation and the planting of grass and emphasizing control of small drainage areas. As of the end of June it had completed control of an erosion area of 1,060 square kilometers. An area of 1,16 million mu had been afforested, and a mountain area of more than 98,000 mu had been closed to permit forests to grow. Grass was planted on more than 220,000 mu of bald mountains and barren slopes, and the number of level terraced fields, level strip fields, compacted sandy fields, and dammed ravines built greatly increased over the first half of last year. This year 649 small drainage basins were listed as the principle areas to be controlled. The area planned for control covered 410 square kilometers, and during the first half of the year 277 square kilometers of it had already been completed. This amounted to 67 percent of the planned task, and 58 percent more was completed than during the same period last year.

Editorial Comment

Lanzhou GANSU RIBAO in Chinese 19 Jul 82 p 1

[Article by Commentator]

[Text] Recently the State Council published "Regulations on Water and Soil Conservation Work," and diligent implementation of these "Regulations" is extremely important for Gansu Province. Erosion in the province is serious. The total amount of silt entering the Huang He annually amounts to more than 50.07 billion tons. Though definite achievements were made following Liberation thanks to the arduous efforts on the part of the broad masses of cadres and people, as a result of the "leftist" disturbance much reckless clearing of land and excessive digging was done and natural cover destroyed in the process of harnessing rivers and mountain streams. There was much putting on of airs and practice of formalism. Engineering measures were emphasized and biological measures slighted. In an effort to do much in a great hurry, blind and rash actions were taken that violated both natural and economic laws causing great losses in water and soil conservation work. In recent years quite a few places have slackened efforts in water and soil conservation work. Large tracts of fertile soil go billowing toward the sea. In some places bare rocks protrude; it has become hard for a drop of water to soak in, and not a blade of grass will grow. Therefore, the water and soil conservation task that stares us in the fact is still a very major one. Leadership cadres at all levels must understand the important significance of water and soil conservation and adtop effective measures to do a good job of water and soil conservation work.

Since Liberation, Gansu Province has accumulated much valuable experience in water and soil conservation work, and every jurisdiction should diligently summarize experiences from their own realities. Experiences in water and soil conservation that have been found workable and effective for many years should be spread. Right now, special attention should go to a close combination of engineering and biological methods, with projects being built before afforestation is done so that living plants will protect projects and projects will protect living plants for mutual advancement, to hasten the pace of control, and to improve economic benefits.

How water and soil conservation work is to be developed following institution everywhere of agricultural production responsibility system is another problem urgently requiring study and solution. For example, organization of leadership, disposition of workforces, assignment of quotas, compensation for labor, distribution of earnings, etc. all require that methods be devised. Some places already possess some experience in this regard, such as use of centralized planning in capital construction of farmland, leaving some land for the peasants use, centralized assignment of workforces, and concentrated efforts toward control. Alternatively there can be voluntary participation in control by groups of households working together, or quotas may be assigned brigades or households, each being responsible for work in their own areas with apportionment of benefits. In afforestation and the planting of grass there can be either centralized planning done by the collective for afforestation and the growing of grass with communes and brigades providing seeds and seedlings, commune members providing the labor, and earnings divided, or there can be assignment to commune members of "three barren lands" with benefits from them going to those who plant them. No matter the method instituted, responsibilities are to be clearly defined, compensation reasonable, and efforts unflagging so that the masses realize real benefits. Only in this way will it be possible to arouse the enthusiasm of the broad masses for large scale water and soil conservation to gain good effectiveness.

HALF YEARLY RURAL LOAN SITUATION REVIEWED

Lanzhou GANSU RIBAO in Chinese 4 Aug 82 p 1

[Article: "Province Issues 270 Million Yuan in Loans For First Half of Year Two Million Commune Member Households Get Loan Support"]

[Text] "Loan amounts large and coverage broad, things supported numerous, and economic benefits remarkable." These are the fundamental characteristics of the province's agricultural loans for the first half of this year.

Gansu's agricultural loans for the first half of this year differ in five particulars from those of former years as follows: One is a tremendous increase in loans, the accumulated total of agricultural loans issued during the first half of the year being 270 million yuan, a 48.6 percent increase over the same period last year and close to the total amount issued during all of last year. Second is the broad coverage of loans. Commune members in the province receiving loans numbered close to 2 million households, which was 60 percent of all farm households. Volume of loans issued them was 174 million yuan, a 1.74 fold increase over the same period last year for an average of almost 90 yuan per household, most of which were poverty stricken households facing economic hardships. Third, was that while supporting grain production, loans for economic diversification also increased. According to statistics, between January and June loans issued for economic diversification totaled more than 71 million yuan to support development of more than 100 different kinds of ventures. Fourth was support to the struggle against disasters with 36 million yuan being issued for commune member livelihood throughout the province. This was a twofold increase over the same period last year and included 10 million yuan of loans for grain rations, a 13-fold increase over the same period last year, and more than 140 million for help to disaster area commune members in buying grain rations. Agricultural banks and credit cooperatives at all levels instituted the "four to the doors" to meet the needs of the contracting of work tasks with individual households as follows: Delivering to people's doors of publicity on policies, visiting people's door to make thorough investigation, going to people's doors to make loan plan arrangements, and going to people's doors to handle loan procedures. They also used methods such as "loan handbooks," "loan cards," and single approval of loans for issuances at separate times. They streamlined procedures to accomodate the masses and to support production to outstanding effect.

USES, PLANTING OF RED BEAN GRASS REPORTED

Lanzhou GANSU RIBAO in Chinese 21 Jul 82 p 2

[Article: "Trial Planting of Red Bean Grass in Gansu Province Has Spread to 24 Provinces and Regions"]

[Text] Following small area trial plantings by the Gansu Agricultural University that brought good results, red bean grass [Onobrychis viciaefolia] which has been acclaimed by foreign pasture experts as the queen of pasture grasses, has been generally welcomed in farflung arid and semi-arid areas, and has spread to 24 provinces and regions.

Red bean grass originated in France and spread throughout Europe, North Africa, and west and south Asia. It also grows wild on the semi-shaded slopes on the north side of the Tian Shan in Xinjiang Province at between 1,000 and 2,000 meters above sea level. In 1960, Gansu Agricultural University brought it in from the USSR for trial plantings. Following many years of growing and evaluation, results shows red bean grass to produce high output of good quality, of strong adaptability, and of good palatability. It is easy to grown, and is bothered by few diseases and insect pests. It is truly a superior pulse family pasture grass that has attracted the interest and serious attention of agriculture departments nationally.

In 1978 the Animal Husbandry Bureau of the national Ministry of Agriculture allocated funds and commissioned the Gansu Agricultural University to establish the country's only red bean grass seed base. By the end of 1981, by using mixing and selection methods, they had bred a superior variety of red bean grass, Changcheng No 1, and obtained more than 12,000 jin of seeds. They provided these superior seeds to more than 250 production and scientific units, and to institutions of higher learning in 24 of the county's provinces and regions to lay a foundation for its promotion over wide areas in arid and semi-arid regions.

In addition to its main use as a livestock feed, red bean grass also makes a fine green manure, a plant for soil and water conservation, and a source of nectar, which has been welcomed in the country's farflung regions. Red gean grass has a long blossoming season. Its flowers have a brilliant color, making it a plant for flower gardens and courtyards to delight the eye and be admired.

JIANGSU

STATISTICS PROVIDED ON STATE FARM, LAND RECLAMATION SYSTEM IMPROVEMENTS

Beijing ZHONGGUO NONGKEN [STATE FARMS AND LAND RECLAMATION IN CHINA] in Chinese No 8, 82 p 11

[Article: "Changes in the State Farm and Land Reclamation Economy in Jiangsi as Shown in Figures"]

[Text] 1. Remarkable Improvement in Economic Effectiveness

The Jiangxi provincial farm and land reclamation system has turned losses into profits for 3 consecutive years beginning with 1979. In 1981 net profits amounted to 15.75 million yuan, an 89 percent increase over the previous year, and 27.15 million yuan was paid in taxes to the state, a 19.27 percent increase over the previous year.

2. Amounts of Farm and Forestry Sideline Product Commodities Increase

In addition to having provided the state with 96.63 million jin of grain, 1.6 million jin of ginned cotton, 2.14 million jin of oil-bearing crops, 1.74 million jin of eggs, and 230,000 cubic meters of timber in 1981, the province also provided more than 40 kinds of products for the foreign export trade. Export commodities were valued at 55.34 million yuan, a 28.7 percent increase over the previous year.

3. Fairly Rapid Speed of Increase in Industrial Production

The gross output value of industry reached 298 million yuan in 1981 and amounted to 66.83 percent of the gross output value of agriculture and industry combined, an 11.1 percent increase over the previous year, and a 48 percent increase over 1978. Some products represented a fair proportion of the province's totals such as monosodium glutamate, which accounted for 40 percent; down manufactures, which accounted for 90 percent; activated carbon, which accounted for 90 percent; ceiling fans, which accounted for 66 percent; and woolen yarn, which amounted to 56 percent.

4. Integrated Agricultural, Industrial, and Commercial Enterprises Make New Strides

In 1981 the province's state farm and agricultural system established 17 integrated companies at all levels participated in by 60 reclamation and cultivation farms, and set up commercial network outlets at 167 places employing 1,481 people, volume of goods sales amounting to 29.78 million yuan with profits of 640,000 yuan.

5. Further Improvement in Staff and Worker Livelihood

In 1981 earnings of staff and workers in state farm and land reclamation enterprises in the province averaged 506 yuan, an 18 percent increase over 1979. This represented a 20 percent increase over 1979 when figured on the basis of an average per capita income of 250 yuan for the population as a whole. During the last 3 years, 330,000 square meters of new dormitories for staff and workers have been built.

ANIMAL-DRAWN CARTS FOR TRANSPORTATION URGED

Shenyang LIAONING RIBAO in Chinese 30 Jul 82 p 3

[Article: "Need To Make Full Use of Role of Animal-Drawn Carts in Rural Transportation"]

[Text] Following institution of production responsibility systems in rural villages, the number of animal-drawn carts in most counties of the province increased by more than 1,000, making them a major force in rural transportation. Animal-drawn carts are characterized by small expense, sturdiness, and easy care. The peasants' burden is small in using them, and one might say that much can be done with small expenditure of money. This fits in with agricultural production relationships and the situation in development of productivity in China at the present stage. Now that rural villages have everywhere established agricultural production responsibility systems, during the period of development toward the mechanization of agriculture, it will be necessary to go through a period in which machines and animals are used at the same time. Therefore, overly early "substitution of machines for animals," and particularly envisioning overly early substitution of tractors or trucks taking the place of animal-drawn carts in rural transportation is not realistic. It is divorced both from the present state of agricultural production and from the present state of energy production.

Reportedly rural communes and brigades in Liaoning Province have purchased more than 4,000 trucks that have been retired from service in cities, and in 1981 individual peasant purchases of medium and small size tractors ran to more than 3,000. Support should be given those used in field operations; however, some of them have also been used in non-agricultural transportation. This not only contends with urban transportation vehicles, but also wastes large amounts of gasoline and diesel fuel.

Tractors should be used principally in field operations and for agricultural transportation where animal-drawn carts cannot be substituted, and trucks should be used primarily in commune and brigade enterprises for the hauling of raw materials and products. Collective or individually owned tractors and trucks should not be used for transportation run as a business in any form. Rural villages should make full use of the role of animal-drawn carts for all forms of transportation.

LESSONS FOR EROSION CONTROL DRAWN FROM 1981 FLOOD DISASTER

Xian SHUITU BAOCHI TONGBAO [BULLETIN OF SOIL AND WATER CONSERVATION] in Chinese No 3, Jun 82 pp 21-25

[Article by Zhang Liming [1728 0448 6900], Shaanxi Provincial Soil Conservation Bureau: "Strictly Prohibit Reckless Denudation and Indiscriminate Clearing of Land to Prevent and Control Mountain Region Soil Erosion--Survey of 1981 Exceptionally Great Flood Disaster in Southern Shaanxi"]

[Text] During July and August 1981, continuously heavy and torrential rains in southern Shaanxi brought torrents of water rushing down mountains, which caused intense erosion, rolling and roaring, collapses, landslides, and mud-rock flows everywhere, and created a disaster situation in mountain regions and flatland areas such as has been rarely seen.

In recent years, southern Shaanxi has had numerous water disasters, and the heavy damage wrought by last year's floods may be accounted for by several reasons. There are natural reasons such as a fall rainy seasons that was long, brought a large volume of rain, and was powerful. This was a direct reason leading to the disaster. Another reason is the lack of centralized planning of river control, and the not very high quality of engineering. However, looked at in terms of macrophenomena, the blindness of people's production activities with the clearing of land everywhere to expand cultivation, and the reckless cutting of trees and denudation of the land that has destroyed the ecological balance and caused intense soil erosion (contemporary erosion) are the main reasons that have turned rainfall into disasters. To a certain degree, the frequency and increasing seriousness of flood disasters in southern Shaanxi are mostly the serious consequences of erosion.

1. Natural Reasons For Soil Erosion in Southern Shaanxi

Three basic natural factors are necessary in order to have soil erosion: One is an external force to produce the washing away--water; second is a corrosive material--soil or mother material; and third is a sloped terrain that is conducive to soil erosion. In the Qinba mountain region of southern Shaanxi, these three elements are present. The inland areas of that region are controlled by the circulation of the monsoon winds. It is the region of the "Western China autumn rains." In most years much rain falls in autumn, and during July and August 1981, in particular, when cold air from the north flowed southward and collided in this area with warm humid air from the south, a highly powerful cold front rain was produced, and the quantity of rainfall greatly increased. A survey has shown that during August 1981, rainfall in that region was between one and four times the volume for the same period over the years, and the period of duration 40 to 60 days. In seven counties, maximum daily rainfall during August was more than 100 millimeters, and in the Yangping mountain pass area of Ningqiang County, on 16 August 172 millimeters of rain fell. In five counties of Hanzhong Prefecture, rainfall during August amounted to more than 500 millimeters. Among them were Lueyang and Ningqiang counties, each of which had more than 700 millimeters. During August Lueyang had 10 rainfalls of more than 30 millimeters each, seven torrential rainfalls of more than 50 millimeters each, and two heavy torrential rainfalls of more than 100 millimeters each. Between 14 and 25 August, the county had 12 days of rain totaling 627.7 millimeters, more than four times the volume of rainfall for the entire month of August in past years. In Qinba County, rainfall during August amounted to 509.6 millimeters or 4.5 times the average 130.3 millimeters of rainfall for the same period over the years. The highly powerful rainfall over a wide area was the meteorological phenomenon responsible for the great flood disaster of 1981.

Geologically and topographically, this region is part of the Tailing and Bashan mountain region. Within the region, except for the Hanzhong Basin, there are range after range of towering mountains. The Tailing mountains average about 2,500 meters above sea level. The mountains are high, the slopes steep, and the terrain precipitous. Through the Daba mountain region is somewhat lower than the Tailing mountain region, because it is fractured and uplifted, limestone distributed over a wide area, and cliffs and precipices extending one after another, the terrain is very difficult of access. In addition, the medium and low mountain areas between the two ranges are formed largely of metamorphic rock, schist, limestone, complex, and granite, which have been strongly corroded and have a fairly thick weathered layer. The hill and low mountain region is composed largely of adamic earth and gravel, which is loose and prone to wash away, flake away, or slide. In short, the terrain here is characterized by "many mountains and little flat land, steep slopes, and a thin layer of soil." It possesses the terrain elements for powerful soil erosion.

2. Human Factors Intensifying Soil Erosion.

The 1981 exceptionally great flood disaster in southern Shaanxi, in mountain areas and flatlands alike, was the evil consequences of serious soil erosion. Soil erosion may be divided into natural erosion and accelerated erosion. Natural erosion is usually slow and is a geological process, but after man joins in the destruction of the natural world, development of the natural erosion process may be greatly hastened, and this is contemporary erosion. In southern Shaanxi, man made elements accelerating contemporary erosion are of the following major several kinds:

(1) Clearing of Steep Slopes For Farming and Indiscriminate Clearing of Land and Arbitrary Planting, Expanding the Eroded Area

In the Qinba mountain region the destruction of forests and clearing of land has been going on for a long time. It began during the waning years of the Western Zhou dynasty when the orindary people of the state of Zheng (modern day Hua County) moved southward to establish homes in Hanzhong County where they began a primitive slash and burn form of agriculture. During the period of the Qin and Han dynasties and the Three Kingdoms era, this area was the land in which military colonists of Liu Bang of the Han and the feudal prince Zhuge [Liang] encamped to begin development of the flatlands. But at that time there were few people here, and damage to the mountain forests was not great. Soil erosion was slight. Subsequently during the reign of Jiajing [1522-1567] of the Ming dynasty, during a period of social upheaval, large numbers of people from the southeast flowed into southern Shaanxi (present day Hanzhong, Xixiang, and Mian counties). They settled in the mountains, built shacks for shelter, felled trees for firewood and for wood to build houses, and cleared the land for agriculture. During the period of the Taiping Heavenly Kingdom, in particular, this area became a battleground for the Nian Army and the soldiers of the Qing dynasty. "During times of small upheaval, flee the cities; and during times of great upheavals flee the countryside," runs an old saying. Large numbers of ordinary people took to the mountains, and with this the low mountains and hills and even the mountain fastness were destroyed. This situation endured right up until the years of the Republic. Because of the gradual decrease in the forest area and the gradual enlargement of barren slopes, the eroded area became increasingly large. On the eve of Liberation, the eroded area of Hanzhong Prefecture amounted to 13,000 square kilometers, which was 47.9 percent of the total land area.

Since the founding of New China, as a result of government's failure to institute planned parenthood policies at once, population increased very rapidly. In 1949, there were only somewhat more than 1.85 million people in all of Hanzhong Prefecture. By 1963, the number had increased to 2,433,000, and by 1980 it had increased to 3,349,000 for a net increase of about 1.5 million people in a 30-year period. As a result of the pressures occasioned by high speed population growth, plus mistakes made in operating programs, not only did no halt occur in the clearing of land and the expansion of agriculture, but, on the contrary, it became worse and worse. According to incomplete statistics from the prefecture, during a period of 30 years the area cleared of forests and opened to agriculture was more than 2 million mu, and in the Qinling mountain region of Baoji Prefecture, about 1 million mu of forests were also destroyed. According to records from Zhenba County, in a 30-year period, an accumulated area of 644,000 mu was cleared for agriculture throughout the county. This included the clearing of 190,000 mu between 1950 and 1958, an average 21,000 mu per year; the clearing of 364,000 mu between 1959 and 1962, an average 91,500 mu per year; no statistics for the period 1966-1970; and the clearing of 88,000 mu between 1971 and 1980 for an annual average of 8,800 mu. A survey done at Qingmuchuan Commune in Ningqiang County during the spring of 1981 showed that

573 of the 859 households in the commune had cleared land to expand agriculture over an area of 493 mu. Furthermore, 30 mountain forest fire disasters, which resulted from burning to clear the land, destroyed 241 mu of forests.

Such large-scale and high speed clearing of the land to expand agriculture has made ever larger the cultivated slopeland area of southern Shaanxi, and as soon as a torrential rain falls, erosion over a wide area results. Measurements made at the Hanzhong Water Conservation Station show that following each torrential rain, upwards of 1 centimeter of top soil is washed away from cultivated slopelands. The reported cultivated slopeland area in Hanzhong Prefecture is 3,146,700 mu (the actual area is somewhat larger), so on this basis, with each torrential rain, 28.32 million tons of top soil are washed away. The large amount of erosion has increased the volume of silt in rivers. Analysis of 24 years of data from the Wuhou Town Hydrology Station on the Han Jiang shows the modulus of silt carried annually above the measuring station to have been 804 tons per square kilometer, a maximum of 2,100 tons per square kilometer, an average volume of silt transported of 2.49 million tons, and a maximum of 8.66 million tons. In the Jialing Jiang basin, runoff is more severe. Analysis of data from the Lueyang Hydrology Station for a 34-year period showed the modulus of silt transported each year above the measuring station to have been 1,680 tons per square kilometer, a maximum of 4,030 tons per square kilometer, an annual average of 3,230 tons of silt transported, and a maximum of 7,740 tons. The foregoing statistical data show the degree of soil erosion here to be no less than that of the loesslands of the northern Wei. Because of the increase in amount of runoff, a corresponding increase has occurred in the volume of silt carried by streams, so in many sections of streams silting is becoming more and more serious. In southern Shaanxi, in particular, gravitational abrasion is dynamic. With each heavy rainfall, the bed load is very great, bringing about a situation of "carrying sand and pushing rocks along, with resulting accumulations in the streams." Sectional measurements taken at Wuhou Town on the Han Jiang show that over a 15-year period the river bed has risen by about an average 0.41 meters per year. Sectional testing at Lueyang on the Jialing Jiang shows an average annual rise of 0.6 meters.

(2) Excessive Felling and Reckless Denudation With Destruction of Forest Plant Cover and a Lowering of Ability to Hold Water Resources

Southern Shaanxi is the major forest area of Shaanxi Province. Though definite achievements have been made in the building of forestry here since founding of the People's Republic, as a result of irrational operating programs and excessive felling, plus society's consumption of timber greatly exceeding the amount of forest growth, the forest area has gradually declined; the quality of forest stands has steadily fallen, and timber reserves have become less and less. A survey done in Feng County shows that during the 18-year period from 1959-1976, the county's mature forest area declined by 480,000 mu or 71 percent of the total mature forest area. In the Taibai forest area, the felling quota for 1979 was 5,500 cubic meters, but 10,453 cubic meters was actually procured. In 1980 the felling quota for the Taibai Forestry Bureau in Shaanxi Province was 53,000 cubic meters, but 56,188 cubic meters were actually felled, 3,188 cubic meters more than quota.

Facts everywhere show that overprocurement has caused reckless felling, and that reckless cutting has exceeded the amount of growth. The Hanzhong Forestry Department has calculated a timber growth averaging 1.33 million cubic meters annually for the prefecture as a whole, while average annual consumption is 1.54 million cubic meters for the prefecture as a whole, or 15.8 percent more than growth. In Baoji Prefecture, the situation is more serious. Annual growth is 696,000 cubic meters, while annual consumption is 1,096,000 cubic meters or 1.57 times the amount of growth. Under the influence of the ultraleftist ideology, in particular, destruction of forest resources in both prefectures as a result of iron smelting, the 3-year hardship period, and the Great Cultural Revolution caused a loss of more than 3 million mu of the forested area of these two prefectures. Forestry inventory data show the forest cover rate for Hanzong Prefecture as a whole to be only 35 percent, and in the counties (or municipalities) of Lueyang, Ningqiang, Zhenba, Xixiang, and Hanzhong, where destruction has been serious, only 28, 26.1, 22.2, 21.8, and 11.3 percent respectively remain. The low mountain and hill regions are currently seriously eroded areas of barren mountains and exposed rock.

As a result of the reduction in forest area, not only do raindrops strike the soil surface directly, scouring away the soil, but the natural repository of soil moisture has been destroyed resulting in a decline in the water holding function of the vast mountain regions. Measurements show that when the space between root systems in forest soil reach 1 meter, the water storage capacity of the forest is from 500 to 2,000 cubic meters per hectare (15 mu). When there are no forests, this water storage does not exist, so naturally the water runs down slopes, greatly increasing surface runoff. Where surface runoff is overly concentrated, serious scouring of the soil takes place, and in a situation of soil saturation, where the terrain conditions are right, mud slides, landslides, and mud-rock slides occur. Incomplete statistics from Lueyang, Ningqiang, Mian, Liuba, and Nanzheng counties show that during the 1981 rainy season, landslides and mud-rock slides occurred at more than 10,000 places, most of them near highways, railroads, and rural towns where destruction of forests and clearing of land was serious, and on exposed cultivated slopes. Representative sampling done in Feng County following the disaster showed a less than 3 percent slide area in forests, only 7.9 percent in sparsely forested areas, 11.4 percent in scrub forest areas, 17 percent on uncultivated grassy slopes, and 40 percent on cultivated slopes. In Ningqiang County, where the area in which forests have been destroyed to clear land is fairly large, the disaster situation was also serious, yet in the Bashan and Tiesuo areas of the county, where the forest cover rate is better than 50 percent, there were 361 and 393 landslides respectively. Meanwhile, in the Yangping area and the Daijiaba area, where destruction has been serious and the forest cover rate is less than 30 percent, landslides were numerous and covered a wide area, occurring at 1,273 and 2,966 places respectively, and causing serious damage.

(3) Neglect of Water and Soil Conservation in Capital Construction and Lack of Centralized Planning in River Control Resulting in the Breaching of Dikes and the Bursting of Dams Adding to the Seriousness of the Flood Disaster

For the past more than 10 years, the scale of construction on three fronts in southern Shaanxi's mountain region has been fairly great, but in the building of industrial plants, the construction of highways, the opening of mines, as well as in the construction of winding mountain irrigation ditches, as a result of neglect of water and soil conservation, large quantities of sand and rock, excess dirt, and mine tailings have gone into gullies, ravines and riverbeds where they block watercourses and add to the mud and sand content. The Daan Asbestos Plant in Ningqiang, for example, annually dumps several hundred thousand tons of tailings into a waterway. This plus soil erosion in the upper reaches resulted in a 1.5 to 2 meter rise in the riverbed during a flood that occurred during the flood season last year. Another example is the section of the Jialing River at Lueyang City where three rivers converge. Because of large quantities of excess soil and waste residues dumped into the river by the Han Steelworks, a cement factory, and from the repair of roads, not only had the river bed been raised, but the river channel had been narrowed. Flood waters could not drain away smoothly, resulting in a congestion of water, a rise in water level, and the bursting of the dike to cause disaster. On the slope of the cutting through which the Baoji-Chengdu railroad line passes, and along the right of way of newly built highways in mountain areas, in particular, because of man-made changes in the stability of the natural mountain mass plus a large population, numerous farmlands, and mud-rock slides occurred everywhere. Survey shows that in the Fengzhou right of way along the Baoji-Chengdu line alone, 92 fairly large landslides occurred. In the area between Honghuapu and Shuangshipu, mud and rock slides occurred in 90 percent of the tributaries on both sides of the Jialing Jiang. They cut the roadbed in 44 places, swept away 10 bridges, and buried three stations, causing interruption of service on that line for 2 months.

In harnessing rivers, as a result of lack of centralized planning or even espousal by some places of the slogans, "Large rivers form a continuous line but small rivers have to move aside," and "Fight with the dragon king for land to get grain out of river shallows," parts of rivers have been blindly filled in to make farmland, thereby narrowing the river bed. For example, Qianjin Production Brigade in Huangsha Commune, Mian County advanced its dike 40 meters into the river, and Jiguang Production Brigade in Laocheng Commune built its river dike in the middle of the river, a difference of 200 meters from the planned line at its farthest point. As a result, when the flood waters arrived, they could not pass freely; the water level rose, and the dikes burst, and thus the damage done by the floodwaters was made greater as a result of man's efforts.

3. Strengthening of Comprehensive Control of Water and Soil Conservation Is a Fundamental Way To Reduce Drought and Waterlogging Disaster Damage.

It may be seen from the foregoing analysis that there are three major factors that cause and intensify floodwater damage in southern Shaanxi. One is natural factors, i.e., the protracted rainfall and heavy torrential rains caused by atmospheric circulation. Second is terrain factors, i.e., the high mountains and steep slopes that make up the topography of the Qinba region, the readily weathered rock and the adamic earth, the gravel, and such geological conditions. Third is reckless felling of trees and arbitrary clearing of land as well as irrational human activities such as denudation of forests in a blind clearing of land for agriculture, fighting rivers for land in contravention of natural laws, and filling in of rivers to make farmland. The overall function of the foregoing three major factors are mutual cause and effect, which brought about last year's unprecedently severe erosion in southern Shaanxi.

We saw clearly in the course of our survey that human activities are an extremely dynamic factor, particularly the clearing of steep slopes, the reckless felling of trees, the cutting into mountains to build industrial plants and mines, careless disposal of gravel and stones, and several instances of "going at things in a big way." These were human activities that destroyed the mountain ecological system, loosened solid materials, and destroyed the balance of the terrain. They hastened erosion and were the main factors in the tremendous damage that was caused. Therefore, in future, major efforts must be made to conserve soil and water and to launch comprehensive control as the fundamental way in which to prevent or reduce drought and waterlogging disasters. The specific actions to be taken are as follows:

1. Planned Closing Off of Mountains to Grow Forests; Major Efforts in Aerial Sowing For Afforestation; and Earliest Possible Restoration of Forest Cover. Southern Shaanxi's climate is mild; rainfall copious; and natural restorative conditions good. These conditions should be used to the full to proceed on the basis of centralized planning to designate sites that should be closed off for the growing of forests and aerial sowing, a specific number of years set, systems formulated, specialized organizations established, and management and protection enhanced. These methods produce forests quickly, require little labor, conserve expenditures for huge benefits, and should be vigorously promoted. At the same time it is necessary to resolutely adopt effective measures. When necessary, reliance should be placed on the law and legal methods used to halt the destruction of forests and the clearing of land, the destruction of grass to grow grain, the burning off of mountains and slopes to clear them, and such bad habits. Forest area should have as their main concern the care of forests to prevent the felling of trees over wide areas and to protect forest resources.

2. Emphasis on Control of Low Mountain and Hill Regions in the Building of Basic Farmlands to Create Conditions for a Return of Land to Forests or Pastures. As population grows, human activities in low mountain and hill regions become more frequent, destruction of forests to clear land becomes serious, the area of cultivated slopes increases. and erosion becomes intense. Major control of this region, with protection of high mountain forests above and protecting the granary on the plain below, would be remarkably effective. As means of control, efforts should be directed toward comprehensive control of entire basins. Southern Shaanxi is a mountain area of soil and stone traversed by mountains and rivers in which there are numerous streams, and in which each basin constitutes an erosion unit. For each unit there must be centralized planning from top to bottom, with selection of superior variety trees for planting in places suitable for forests, preparation of the land for

afforestation, and development of native forestry byproducts. In hill areas where slopes are gentle, terraced fields rimmed with stone or earth may be built in the construction of basic farmlands. Narrow gullies and ravines should be dammed up to intercept mud and sand and to stabilize the ravines and gulches. On tracts in wide river valleys, fields should be uplifted and small water conservancy developed. Along the porifera of the hill area, and in the triangular area formed by Mian, Lueyang, and Ningqiang counties at the source of the Han Jiang, the low mountain area is fairly large and cultivated slopes numerous. Lamelliferous scouring occurs everywhere, and terraced fields should be energetically constructed. Slopes not suited to cultivation should be gradually withdrawn from cultivation for reversion to forests or grasslands. For the present, forests and grain may be grown in alternating strips so as to prevent or reduce erosion.

3. River Control Requires Centralized Planning, Comprehensive Control, and Prevention of Flooding. The flood disaster in southern Shaanxi in 1981 resulted primarily from the rains having lasted for a long time, their intensity, and their broad area of coverage. The flood prevention standards of most river defense projects could not withstand such rarely encountered floodwaters. However, in work terms, the floods were part and parcel of the present lack of centralized planning of river control and everyone going his own individual way. The streams in the Qinba area are a part of the mountain area streams. When the volume of floodwater is large and the flow violent, low-lying areas and river flood plains become extremely prone to flooding. Therefore, in controlling rivers, it is necessary to do centralized planning for upper and lower reaches, and for left and right banks in a harnessing of both the mountains and the rivers. In addition, it is necessary to adopt biological measures in combination with engineering measures for comprehensive control. Needed water storage projects to effect control should also be built to intercept and impound floodwater. When building dikes and dams, within dikes afforestation should be done to protect the dikes. Outside the dikes, billow prevention forests should be created, forests, grass, dikes, and low banks between fields used to form a coherent whole in the hope of gaining maximum preventive benefits. Overall planning that takes all factors into consideration should be done; there should be unified control of water, and strengthening of management in order to assure safety.

4. Improved Understanding: Establishment and Perfection of Basinwide Water and Soil Conservation Organizations; and Genuine Strengthening of Leadership For the Building of Southern Shaanxi's Mountain Regions. Both the Han Jiang and the Jialing Jiang are major tributaries of the Cheng Jiang. Within the basins of these two rivers are high mountains and steep slopes on which the soil layer is very thin. Once it is washed away, there will be no end to grief. In addition, this area contains numerous streams with a large volume of flow, so protection and development of water and soil resources here permits not only a reduction or avoidance of floodwater damage here, but also relates to the issue of development and use of the Chang Jiang. However, formerly people always supposed that since the mountains were green and the waters clear here, there was no erosion, so they did not give serious attention to soil and water conservation work in southern Shaanxi. This was

a mistake in our work, and we must learn this lesson. In order to develop and build southern Shaanxi's mountain regions, to make full rational use of the water, soil, grass, and timber resources here, to protect the ecological system, and to reduce flood and drought disasters, it is recommended that basinwide soil and water conservation organizations be established to coordinate development of comprehensive control work by relevant agricultural, forestry, water conservancy, and animal husbandry sectors so as to build the mountain regions of southern Shaanxi into economically flourishing new mountain areas.

METHODS TO CONTROL FLOODING, CONSERVE WATER URGED

Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 3, 1982
pp 14-15

[Article: "Conscientiously Generalize Experiences and Lessons in Excelling in Future Water Conservancy Work"

> [Text] Editor's note: In August 1981, a historic high-water-mark flood erupted in Hanzhong Prefecture and Baoji Municipality of Shaanxi Province, inflicting heavy damage. The hydroelectric bureau of the province organized flood investigation teams for on-site inspection and investigation in key damage areas to generalize experiences and to analyze the causes of these disastrous floods. The findings show the main feature of the disaster was excessive rains, causing three flood diasters: sliding slopes, mud flow, and rock slides. The basic causes of the disaster were high-pressure ridges of warm moist air over the Pacific Ocean, frequent typhoons, intensive sunspot activity, and abnormal weather. This caused long persistent heavy rains to spread over wide areas of Hanzhong and Baoji, causing rivers to overflow and inflicting disaster. There were many factors causing the floods: the direct cause was the heavy, prolonged rain. Also contributing to the flooding was the geography and history plus problems in governmental functions--less than ideal urban planning, unsound layout in industry, agriculture, commerce and communications; mismanagement in dike construction, and damages to forest and plant cover. The investigative report analyzed the situation. The following is an abbreviated report (Part III) quoted here for readers' reference.

Viewpoints and Opinions to Several Existing Problems:

I. Relationship Between Forest and Flood

Forests provide many benefits, such as moderating the climate, preservation of watersheds, soil and water retention, prevention of wind damage, keeping the sand compact, environmental beautification, and removal of pollutants. There are positive effects from regulating river and steam flow, reducing silt

silt deposit onto river channels and water reservoirs, and extending the service life of construction projects. This is why forests are called "dispatch rooms of mother nature" and "green water reservoirs." However, forests play a conditional and limited role in water storage and soil retention; the forests' role is diminishing with increased rainfall intensity. In addition, the role is closely related to terrain, geomorphology, and geological structure. In case of heavy rainstorms during the flood season, forests cannot effectively store flood water. It has been proved that forests fail to control floods.

At 4 o'clock in the afternoon on 22 August, the peak flood flow in the Han River passing Hanzhong Municipality was 8,310 cubic meters per second; the main source of the flood peak was the Bao River. At the Madao Hydrometric Station on the Bao River, the peak flood flow on 21 August was 5,810 cubic meters per second. At 13:43 hours on 22 August, the drainage flow at the gate outlet of the Shimen Water Reservoir was 4,830 cubic meters per second, which is 58 percent of 8,310 cubic meters per second at Hanzhong Municipality Hydrometric Station on the Han River. The plant-cover conditions of this valley are as follows: 77.8 percent of Taibai County in the upper reaches of the Bao River Valley (3,861 square kilometers), and 58.8 percent for Liuba County; forest plant cover for the entire valley is about 60 percent. Forest plant cover can be said to be relatively good. The Madao Hydrometric Station is situated on the down-river side of the middle streams of the Bao River, 28 kilometers from the Shimen Water Reservoir; the hydrometric station controls 3,415 square kilometers of the valley. There were low amounts of precipitation before 9 August; at the time, the soil moisture (in valley soil) was 17.2 mm. On 9 August, there was 54.7 mm of rainfall; the peak flood flow was 292 cubic meters per second, corresponding to a flow of 27.3 million cubic meters; the data were converted to 8.0 mm of net rain and a drainage coefficient of 0.15. There was no rain from 10 to 12 August. On 13 August, here was 2.8 mm of rainfall, and the soil moisture content in valley soil was 46 mm. On 14 August, there was 25.5 mm of precipitation, and the soil moisture content in valley soil was 62.4 mm. From 14 to 20 August, total precipitation was 348.2 mm, with four flood peaks (more than 1,000 to 3,000 cubic meters per second), corresponding to a flow of 298.6 million cubic meters; the data were converted to a net rainfall of 87.4 mm and the drainage coefficient was increased to 0.94. These data indicate that 85 percent of the precipitation (before 9 August) was accounted for by forest retention, downward seepage, filling of depressions, and evaporation because the climate in this period was relatively dry. However, in the later period after long persistent rainstorms, valley soil reached a saturation point and the total of the four aforementioned categories accounted for only 6 percent of precipitation. These data indicate that the forests' role of flood retention and storage was limited in the situation of persistent rainstorms in August 1981. We must point out that forests have a definite effect on the retention of ordinary rainstorm water, as well as on lessening disastrous floods; under certain environmental conditions, forests can exercise a remarkable role. We must stress, however, that in the area of Qinling and Bashan Mountains, the soil depths were thin; plant cover had been damaged; and soil and water losses were intensified. These are danger signs. We believe that it is necessary to protect closely the existing forest resources, to forbid opening up virgin land by wiping out forests, to add to forested area, to increase the percentage of plant cover, and to prevent water and soil losses en bloc.

II. Opinions on Constructing Dikes Along Medium-sized and Small River Channels

In recent years, regulations on medium-sized and small river channels were promulgated in provinces of China; many dike and river protection projects were completed. However, many problems still remain in our planning, design, construction and management, as this flood indicated. We should conscientiously generalize these experiences and draw lessons from them.

The four following problems need to be noted during planning: (1) Economic benefits should be stressed by conducting studies on necessity and feasibility. (2) Appropriate standards and guidelines should be complied with by adopting an adequate flood-prevention standard and by calculating the flood peak flows used to prevent the disaster. (3) During calculations of water flow cross-sections, we must take into account related conditions of water and sand, stable gradient, and river feature adequately to select dike distance and height, not too high and not too narrow. (4) Deal with all problems in river regulation and the relationship between left and right banks, as well as between upper and lower streams. Spur dike projects should not be so built as to form water barriers, with water overflowing into adjacent areas.

There are six problems in design and construction as follows: (1) If two flood prevention standards are used in a river sector (as in the case of different standards in urban area protection and in farmland protection), lattice dikes should be built at the sites of upper streams to protect the area from water flowing in by rear detours. (2) Erosion depths of river channels should be calculated in designing adequate foundations. (3) In river sectors with ready access to soil when the dike body is stable but difficulties exist in digging deep foundations, lead-wire cages or soft material protection (such as bundled bamboo baskets) can be used on bank slopes facing the water; stone masonry (not mortar rubble masonry) can be used to protect bank slopes facing the onrushing water. (4) In the case of a dike project with sector-by-sector design and construction, two ends of the project in the upper and lower streams should be joined to solid reliable locations such as high rocky pits or strong buildings to stop water flooding from the rear. (5) Dike fills should meet strict quality standards and bank slope projects should be constructed by strictly adhering to established design. (6) Reinforce the protection design at confluences of tributaries entering the main channel, and the water onrushing sector at bends of rivers.

In management, sound organizations should be established to improve the situation of river channel mismanagement. We should ban activities which damage dikes or empty waste materials into channels. Routine maintenance and repair work should be performed conscientiously.

III. Build Regulating Reservoir Projects as Per Plans

Up to the end of 1980, in the Hanzhong Prefecture and Baoji Municipality 2 large reservoirs, 10 medium-sized reservoirs, and 486 small reservoirs had been built with a total water capacity of 1,133,000,000 cubic meters. In this near-record-setting rainstorm and flooding, only two small (category II) reservoirs in Baoji Municipality collapsed; most water conservancy facilities stood the test of flood, especially in the Hanzhong Prefecture, not a single dam failed. This was a success story in reservoir construction. In the flood period, these reservoirs of all sizes had some success in flood retention and protection. The combined effect of Fengjiashan and Wangjiayai reservoirs on the Qian River, as well as the incomplete Shitou River reservoir reduced the flood peak by 1,980 cubic meters per second at Weijiabao Station on the Wei River. In the case of Shimen Reservoir, it stored 30 million cubic meters of flood water and lowered the flood peak by 1,550 cubic meters per second to protect Hanzhong Municipality in relieving the flood diaster. Another case, that of the Duanjiaxia Reservoir in the upper reaches of the Qian River, the peak flood of the river channel was lowered from 436 to 36 cubic meters per second in protecting the county seat of Longxian. These examples are sufficient to illustrate the role of water reservoirs in flood prevention and flood peak reduction during the struggle against this kind of disaster. However, the reservoir capacity is too small compared to the onrushing river flow, so the flood eventually gained the upper hand. Therefore, we suggest planning regulation projects, when economically feasible, of the Zhouzhihe River reservoir, Jiebaiquan and Qingqiaopu reservoirs on the Bao River, and the Jiaoyai Reservoir at Chenggu to protect Xianyang County, Xi'an Municipality, Hanzhong Municipality, and Chenggu County in order to exploit the comprehensive benefits of flood prevention, irrigation, power generation, and water supply.

IV. Urban Planning and Plant Deployment Should Be Coordinated With Flood Prevention Projects

During plant and warehouse site selection and deployment of the commercial distribution network, some organizations pay attention only to immediate benefits but neglect the overall benefits gained and damage eliminated by the river channel requirements. As a result, some avoidable damage has been inflicted. In the future, urban planning and plant deployment should give due attention to the requirements of flood prevention and should be closely coordinated with flood prevention programs in urban areas. In addition, procedures of capital construction should be adhered to; geological prospecting should be done in advance and proper measures for prevention should be adopted in order to reduce damages caused by descending slopes, landslides, mud flows, and rock slides.

From the above-mentioned, we stress in particular adhering to routes with comprehensive regulation. On one hand, we should strictly protect existing forest resources by forbidding the opening of virgin land by wiping out forests; we should also vigorously engage in tree planting and linking up forests in order to increase the ratio of forest cover and water and soil retention. On the other hand, we should build necessary dike projects along the banks of the Pingchuan sector of the Han River and in the middle and upper streams of Wei River to coordinate planning and meet local conditions. Maintenance and management of existing dikes should be strengthened to clear out barriers to flood passage in river channels. In the planning of urban development, we should give due heed to flood prevention requirements, and the effects of descending slopes, landslides, mud flows, and rock slides for a rational layout. Some essential regulating water reservoirs should be built along principal tributaries. Our activity in the future should be directed to these above-mentioned areas.

BENEFITS OF MARGINAL ANALYSIS OF COSTS, OUTPUT EXPLAINED

Beijing ZHONGGUO NONGKEN [STATE FARMS & LAND RECLAMATION IN CHINA] in Chinese No 8, 82 pp 12-13

[Article: "Application of Marginal Analysis to Improvement of Economic Effectiveness"]

[Text] A major indicator of how good a job is being done in agricultural production on state-owned farms is fairly high economic effectiveness. We conducted a survey and analysis of wheat production costs and economic effectiveness for a number of eyars at the Wusi Farm in Shandong Province, which showed that despite steadily increasing wheat output and profits, nevertheless the farm had some problems meriting attention. Let us first detail the survey and analysis circumstances below.

1. Changed Circumstances in Wheat Production Costs and Economic Effectiveness

The Wusi Farm has 4,200 mu of cultivated land, about 3,200 mu or more than 70 percent of which was sown to wheat every year. The farm made profits totaling 447,100 yuan from the growing of wheat from its first profits in 1975 until 1981, its annual profits averaging 19.95 yuan per mu, and its cost profit rate being 41.2 percent for fairly high economic effectiveness. Beginning with cost analysis, we analyzed wheat's economic effectiveness, the changes in development being shown in Table 1.

Table 1. Wheat Output and Cost Situation Over the Years

Year Item	1974	1975	1976	1977	1978	1979	1980	1981
Yields per mu (jin)	336	407	387	347	330	558	415	402
Cost per mu (yuan)	27.00	29.15	33.00	32.15	34.15	50.00	52.30	58.22
Cost per jin (yuan)	0.080	0.072	0.085	0.093	0.104	0.054	0.126	0.145

In the 8 year period between 1974 and 1981, wheat yields went from 336 jin per mu to 402 jin per mu for a 19.6 percent increase, while costs rose from 27 yuan per mu to 58.22 percent for a 1.16 fold increase. Though wheat output **rose greatly**, owing to the higher cost per mu, the per unit cost also rose greatly. Wheat costs rose from 0.08 yuan to 0.145 yuan per jin for an 81.3 percent increase.

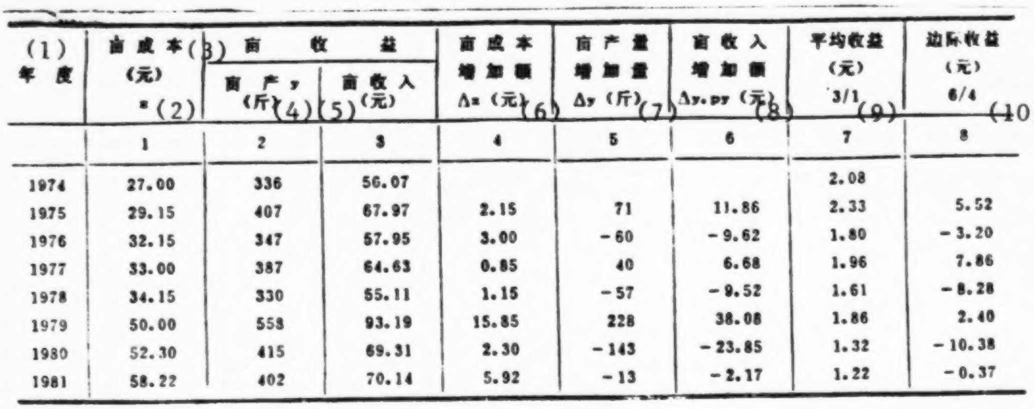
A look at the foregoing situation shows a steady increase in the cost per mu of wheat. This reflected the farm's movement from extensive to intensive operations. This movement did not develop evenly. In the 5 year period between 1974 and 1978, wheat costs per mu rose fairly slightly. This period reflected adherence to an attitude of circumspection toward costs, and attention to pursuit of economic results from costs in consequence of which per unit costs were fairly stable and economic effectiveness was fairly high. Between 1978 and 1979 a great leap in costs appeared. Costs rose suddenly from 34.15 yuan to 50 yuan per mu, a 46.4 percent increase, while wheat yields increased from 330 to 558 jin per mu, a 69.1 percent increase. Because the extent of increase in output exceeded the extent of increase in costs, costs of product fell from 0.14 yuan to 0.054 yuan per unit of area, a decline by half for the lowest product cost and optimum economic results in many years. Plans called for continued lowering of costs and higher output for greater economic effectiveness between 1979 and 1981. However, this hope was greater than the farm's realities permitted, and the anticipated goals were not obtained, with the result that economic results declined greatly. In 1981 costs of wheat production rose to 58.22 yuan per mu, a rise of 16.4 percent while yields fell to 402 jin per mu, a decline of 28 percent, occasioning an increase in costs of 0.145 yuan per jin or a 68.7 percent rise.

2. Analysis of Marginal Effectiveness of Costs

In an overall sense the economic efficiency of Wusi Farm's wheat production was rather good. However, marginal analysis of economic benefits derived from increased costs year by year shows numerous conspicuous problems. Supposing: costs per mu to be x and yields per mu to be y, the average benefits being y/x; amount of increase in costs per mu being Δx, and amount of increase in yields per mu being Δy, the marginal yields from production costs thus being $\Delta y/ \Delta x$; if the per unit price per jin of wheat is py (the prevailing price being 0.167), the marginal benefit from production costs would be $\Delta y.py/ \Delta x$. Our analysis of marginal benefits as derived from survey data are shown in Table 2.

It may be seen from analysis of Table 2 that marginal effectiveness was greatest in 1975 and 1977. This was because during these two years $\Delta x < \Delta y.py$. After 1977, continued major increases in production costs brought a decline in marginal effectiveness, and 3 of the 4 years showed a negative value, i.e. $\Delta x < \Delta y.py$. Despite the all-time high yields of 558 jin per mu in 1979, marginal effectiveness was less than one-third that of 1977. The foregoing analysis shows that application of marginal analytical methods to determine optimum economic results is extremely important.

Table 2



(1) 年 度	亩成本 (元) x (2)	(3) 亩 收 益		亩成本 增加额 Δx (元) (6)	亩产量 增加量 Δy (斤) (7)	亩收入 增加额 Δy.py (元) (8)	平均收益 (元) 3/1 (9)	边际收益 (元) 6/4 (10)
		亩 产 y (斤) (4)	(5) 亩收入 (元)					
	1	2	3	4	5	6	7	8
1974	27.00	336	56.07				2.08	
1975	29.15	407	67.97	2.15	71	11.86	2.33	5.52
1976	32.15	347	57.95	3.00	-60	-9.62	1.80	-3.20
1977	33.00	387	64.63	0.85	40	6.68	1.96	7.86
1978	34.15	330	55.11	1.15	-57	-9.52	1.61	-8.28
1979	50.00	558	93.19	15.85	228	38.08	1.86	2.40
1980	52.30	415	69.31	2.30	-143	-23.85	1.32	-10.38
1981	58.22	402	70.14	5.92	-13	-2.17	1.22	-0.37

Key:

(1) Year
(2) Cost per mu (yuan) x
(3) Benefits per mu
(4) Yield per mu (jin) y
(5) Income per mu (yuan)
(6) Increased cost per mu (yuan) Δx
(7) Increased yield per mu (jin) Δy
(8) Increased income per mu (yuan) Δy,py
(9) Average net benefit (yuan) 3/1
(10) Marginal benefit (yuan) 6/4

3. Analysis of Cost Structure

In an overall sense, analysis of marginal effectiveness of costs reflects the contrasting relationship between added costs and increased income. But a very large number of items make up costs in agricultural production, so what is the major area in which economic effectiveness can be improved? It is also necessary to make a specific analysis of the structure of costs. There are 10 different items making up the cost of wheat production. Those accounting for the greatest proportion and changing fairly greatly are shown in Table 3 (averaging expenditures per mu).

Among the three cost items shown in Table 3, the ratio of total costs is greatest for fertilizer and pesticides (mostly fertilizer), and during the 8 year period from 1974 to 1978, they accounted for more than 40 percent of total costs. The extent of increase in fertilizer expenses was very great, increasing from 12.76 yuan per mu in 1974 to 23.09 yuan per mu in 1981, or almost double. However, a look at the increase in yields resulting from fertilization shows yield increases to have been vastly lower than the increase in fertilizer expenses. This brings a problem into sharp relief. For future increases in the amount of fertilization, the optimum value of marginal output derived should be used as a yardstick for measuring the additional amount of fertilization. Only in this way can one derive optimum economic effectiveness.

Table 3

Year Item	1974	1975	1976	1977	1978	1979	1980	1981
Fertilizer and Pesticide	12.76	7.39	13.51	12.33	16.27	16.07	16.39	23.09
Machine Operation Expenses	4.63	4.85	4.15	5.20	2.77	9.15	11.53	12.12
Indirect Expenses	3.83	10.91	8.10	5.48	7.72	10.63	21.41	9.92

Note: Indirect expenses included enterprise management expenses and joint production expenses.

Expenses for machine operations also accounted for a substantial proportion of the cost structure. Up until 1979 it accounted for from 16 to 18 percent of total costs; after 1980, it increased to more than 20 percent. It went from somewhat more than 4.00 yuan per mu to somewhat more than 12 yuan per mu, a threefold increase. Costs for machine operations are fairly stable for the growing of wheat. The need to create soil moisture as a result of the drought of the past several years slightly increased the amount of work, and the increase in machine operation expenses was occassioned principally by poor maintenance and care, which created an increase in costs per standard mu. Future attention to maintenance and care of machines for a lowering of machine operation expenses is a major way in which to increase economic effectiveness.

The fairly numerous indirect expenses are a major element adversely affecting economic effectiveness. During the past several years both enterprise management expenses and joint production expenses have risen tremendously. They rose from an average 3.83 yuan per mu in 1974 to about 10.00 yuan per mu, an almost threefold increase accounting for 20 percent of total costs. Rise in indirect expenses increased both costs per unit of area and costs per unit of product. The relationship between indirect expenses and direct technical measures in production is not great, so vigorous efforts at conservation should be made in future to the maximum extent possible.

4. Strengthening of Economic Management In Order to Increase Economic Effectiveness

All production on state-owned farms should have as its fundamental point of departure increase in economic effectiveness. This requires that the farms strengthen economic management, and operate on the basis of economic laws and natural laws. Economic management should serve to increase economic effectiveness.

Management of costs is a major ingredient in the economic management of farms. Application of complete cost accounting data to analyze dynamic trends and to analyze static structure can forecast the direction of added costs, determine the appropriateness of costs, and gain the optimum obtainable economic effectiveness. Agricultural product production costs reflect the degree of intensiveness of agricultural production. The object of cost management is not to shrink costs passively, but rather should be to actively add to costs to gain the highest degree of improvement in economic effectiveness, i.e. when the value of increased output is greater than added costs to add to costs. The task of cost management is to find this optimum degree of intensivity.

Use of marginal analytical methods to conduct marginal analysis of costs and their economic effectiveness makes it possible to see clearly at any stage the economic results of added costs, thereby being able to select the amount of cost investment that will derive optimum economic effectiveness. When the objective conditions for increasing costs are not present, one should not blindly increase costs. Our research and dissemination in this regard is currently still very insufficient and urgently requires strengthening.

SHANXI

EFFORTS TO CONTROL EROSION UNDERWAY

Beijing ZHONGGUO NONGMIN BAO in Chinese 19 Aug 82 p 1

[Article: Luliang Prefecture Hastens Pace of Water and Soil Conservation Work; Genuinely Strengthens Leadership and Promotes Advanced Experiences"]

[Text] Since the Third Plenary Session [of the 11th Party Central Committee], Luliang Prefecture in Shanxi Province has genuinely strengthened leadership, has summarized and spread experiences, and has hastened the pace of water and soil conservancy work.

Since the founding of the People's Republic, Luliang Prefecture has brought erosin under control over a 6.41 million my area, or 35.6 percent of its total land area. Following the Third Plenary Session, the party's rural policies stimulated the enthusiasm of the broad masses of people, and between 1979 and 1981, 450,000 mu was brought under control annually. This amounted to 2.5 percent of the total soil erosion area and was 157 percent faster than during the previous 29 years.

In order to strengthen leadership of water and soil conservation work, the prefecture's government administrative offices established a soil and water conservation bureau, which annually convened two conferences on soil and water conservation to summarize and spread experiences and to formulate overall programs for farming, forestry, and animal husbandry in which forestry predominated, and put forward the "two soil method." By this was meant the division of existing cultivated land into two kinds. One kind of soil was for development of grain and oil-bearing crops primarily to solve the problem of food for the masses. The other soil was premarily for development of economic forests to solve the problem of the masses spending money. This specifically provided for the "building of land, the planting of trees, the growing of grass, attention to livestock, interception of water, and the building of roads." Methods of control used three combinations: 1. a combination of botanical measures and engineering measures, attention going first to botanical measures; 2. a combination of control of ravines and control of slopes, attention going first to control of slopes; and 3. a combination of control of the upper and control of the lower, attention going first to controlling the upper. Throughout the prefecture numerous good representative cases occurred. One was in

Zhongtanggou Production Brigade in Fangshan County where between 1973 and last year a total of 1,030 meters of river dams were built, 560 mu of river shallows brought under control with benefits already accruing from 400 mu, and the gradual return to forests and pasturage of cultivated slope land. The cultivated area has declined from the former 3,100 mu to 1,500 mu; total grain output has increased from the former 130,000 jin to 328,000 jin, and a change has taken place from the eating of 30,000 jin of grain resold by the state to the sale of 50,000 jin to the state. Following the withdrawal of land from cultivation for return to forests, active afforestation and planting of grass was done. The amount of woodlands averaged 8.5 mu per person in the brigade, and the amount of grassland 1 mu. The livestock industry saw commensurate development. Now this prefecture is actively adopting measures to bring to a halt the situation in some areas of clearing steep slopes and destruction of forests to clear land. In serious cases, it is meting out punishments to fairly good effect.

TITLE: "An Experiment in Numerical Forecasting of Typhoon Tracks With Nested Models"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 257-270

TEXT OF ENGLISH ABSTRACT: In order to improve the prognosis of typhoon movement, the nested mesh schemes for the primitive equation models are presented in this paper. An experiment on prediction for some examples had been made by using these schemes. It is shown from the calculation that the methods for conjunction and adjustment of dependent variables at the juncture of coarse-mesh and fine-mesh are effective and the axial-symmetrical typhoon circulation simulated by the normal distribution is suitable for the prediction of typhoon movement by using numerical models. One of the schemes was tested during the typhoon season in 1980 and resulted in the improvement, to a certain degree, in the forecast of the typhoon tracks. This paper was received for publication on 12 December 80.

TITLE: "An energetic Analysis of A Landed Typhoon"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 289-299

TEXT OF ENGLISH ABSTRACT: The case selected in this study is an intense typhoon (Billie) which moved over the Southeast China and interacted with an extratropical frontal system. Kinetic energy (KE) budget and available potential energy (APE) were computed by using the quasi-lagrangian scheme during the period of 10-12 Aug 1976. The main results of this study are: (1) In the weakening process of the landed typhoon, exchange of KE with the environment was small. Then, the typhoon could be considered as a "quasi-closed" system. (2) In the various weakening stages of the landed typhoon, the thermodynamic and dynamic processes were different. When the typhoon moved just over land and accompanied with heavy rain, the latent heat and moist convection were still the major source of KE. The energy sink due to cross-contour flow in the upper troposphere was the important reason for the decrepitude of the typhoon. The barotropic process was dominant in the decrease of KE. However, after the typhoon interacted with the westerlies, the KE generation by

[continuation of QIXIANG XUEBAO No 3, 1982 pp 289-299]

baroclinic process increased and the frictional dissipation played a significant role in this stage; (3) Throughout the period of interest, large amount of APE entered into the environmental atmosphere through the lateral boundaries of the typhoon circulation. This may be one of the major processes of interaction between the typhoon and the surroundings.

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 310-318

TEXT OF ENGLISH ABSTRACT: In this paper the kinetic energy, sensible and latent heat budgets over limited area are calculated during the heavy rainfall in July 1977. In the heavy rainfall system sensible and latent heat, supplied from surroundings, are converted into kinetic energy, which is transported out of the area at upper levels by horizontal flux divergence. Subgrid-scale motion leads to increase of sensible heat and decrease of latent heat of the grid scales of motion. Transfer of kinetic energy from subgrid to grid scales of motion is observed in the area with most intense rainfall, but an opposite transfer occurs in its surroundings. Some results of this paper are useful for designing numerical models of precipitation.

TITLE: "Wind Regime Beneath Crop Canopies and Its Model"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 335-343

TEXT OF ENGLISH ABSTRACT: The characteristic features of horizontal and vertical wind-speed distribution beneath crop canopy are discussed. It is found that there exists an assymmetric "S" pattern vertical profile. Deficiency of commonly used models of horizontal and vertical profiles inside crops is also analyzed. A new model describing wind speed inside crops is proposed on basis of theoretical analysis and empirical fitting. According to this new model the computed mean wind speed, whether in horizontal distribution or along vertical profile, is in fairly good conformity with the real data.

TITLE: "Some Microclimatic Effects of Reclamation"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 353-360, 326

TEXT OF ENGLISH ABSTRACT: In this paper, the field observation data of cultivated and uncultivated land at Hulunbeier for two years in succession are used. The authors analyzed the variations of soil hydrothermal condition, atmospheric dynamic and thermodynamic condition near the ground, and surface heat balances during the period between spring and summer (May-June)after reclamation. It is indicated that the microclimatic effects of reclamation are many sided and obvious, especially, the thermodynamic effects. So, one must pay attention to the influences of such human activities as reclamation on climatic conditions.

TITLE: "A Criterion of Autumn Rain Forecast in Shanghai"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 361-365

ABSTRACT: Based upon the autumn rain and related data of Shanghai of the period 1874-1979, a graph is made to depict the average rainfall of 10-day periods of every month in these 106 years. The graph demonstrates clearly that just like the plum rains in the spring, the autumn rains in Shanghai are concentrated in a rainy season, from late Aug to middle Sep. The amount of rain in that period has a great effect on the yield of cotton. Surveys indicate that rains heavier than 210 mm may cause a 30 percent yield reduction of cotton. Following descriptions of the atmospheric circulation pattern and the weather characteristic of that period, the paper concludes that the beginning, continuation, and conclusion of autumn rains are the results of the 2 great adjustments of long wave trough and ridge of the westerlies and following the each of the 2 adjustments, the secondary high declines and receded. Finally, a correlation between the average intensity of the secondary high at 500 mb in Aug and the subsequent autumn rainfall is discovered. The average intensity of the secondary high in Aug is used as a criterion to check the amount of rainfall in Sep of 1979 and 80. The results correspond very well with the reality.

TITLE: "Estimation of Artificial Rainfall Effect"

SOURCE: Beijing QIXIANG XUEBAO [ACTA METEOROLOGICA SINICA] in Chinese No 3, Aug 82 pp 381-385

ABSTRACT: With reference to the quantitative estimate equation suggested by Simpson et al in the JOURNAL OF ATMOSPHERIC SCIENCE (Vol 30, 1973 pp 1178-1190), the paper demonstrates mathematically that a certain deviation exists in the estimation using that equation. Effect of an artificial rainfall test in Hebei Province using urea as the catalyst is analyzed with the equation of Simpson as well as the method proposed by the author in the paper. With Simpson's technique, the relative increase of rainfall is 33.5 percent; with the author's technique, it is 49.3 percent. The difference remains apparent.

TITLE: "Survey Report of Fava Bean [Broad Bean] Production in Jingzhou Prefecture"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 9, Sep 82 pp 8-11

ABSTRACT: A survey of broad bean production in Jingzhou Prefecture was carried out in 11-20 May this year jointly by the Cropping System Research Conference, the Grain Crop Society, Plant Protection Society of Hubei Provincial Society of Agriculture, the Jingzhou Prefecture Society of Agriculture, and the Jingzhou Prefecture Bureau of Agriculture, and the leaders and specialists of several local bureaus of agriculture. In 1953, broad bean was a summer crop in the prefecture for adjusting soil fertility, having an acreage of 2.23 million mu and a yield of 127 jin/mu. The low temperature in 1956 led to severe reduction of yield and the leaders of that time ideologically emphasized the production of major food grains to result in gradual decrease of the acreage of broad beans. It was down to 882 thousand mu in 1980. Since then, the leaders of various levels have noticed that excessive continuous cropping of wheat and cotton has caused serious damage to soil fertility. A series of measures have been adopted to introduce superior breeds of broad beans, to extend its high yield technology, and to organize teams to learn from regions outside the prefecture. In 1982, the acreage was restored to 996 thousand mu and an average

[continuation of HUBEI NONGYE KEXUE No 9, 1982 pp 8-11]

yield of 189 jin/mu was obtained. The yield was especially high in some commune-brigades of rice paddy areas, reaching 300-500 jin/mu. Aside from the acreage and the condition of production of 17 brigades of 15 communes of 9 counties of the prefecture, the paper also reports the result of using broad bean crop before cotton to promote the yield of cotton and the result of using broad been in rice paddies to raise the crop-repeating index. Key techniques for obtaining high and stable yield of broad bean are also suggested.

TITLE: "Research on Winter Prospering Rape"

SOURCE: Wuhan HUBEI NONGYE KEXUE [HUBEI AGRICULTURAL SCIENCES] in Chinese No 9, Sep 82 pp 15-17

ABSTRACT: Using the form of growth of rape plant in winter (before Little-cold = 6 Jan] as the standard, if there are 5-6 green leaves, with a leaf area coefficient < 0.5 and a dry weight of plants $\leqslant 100$ jin/mu, it is called winter-holding rape; if there are 7-8 leaves, with a leaf area coefficient of about 0.8 and a dry weight of about 150 jin/mu, it is called winter-vigor rape; if there are 9-10 leaves, with a leaf area coefficient above 1.2-1.5 and a dry weight of above 200 jin/mu, it is called winter-prospering rape. There is a close relationship between this form of growth and the subsequent yield. The yield of the winter-prospering type of rapeseed is 89.4 jin/mu higher than the winter-vigor type, an increase of 39.6 percent, and 158.9 jin/mu higher than the winter-holding type, an increase of 101.7 percent. Results of an experiment in 1978-80 also indicate that the better is the winter-prospering form, the higher is the yield. The spring growth phenomenon and the physiological characteristics of winter-prospering rape crops and the relationship between the quality of growth in the winter and the subsequent yield are explained. The environmental conditions necessary for obtaining winter-prospering rape in the middle reaches of Changjiang, including various experimental data, are introduced.

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

THEORY PROPOUNDED FOR EVALUATING, READJUSTING AGRICULTURAL STRUCTURES

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese
No 8, 23 Aug 82 pp 3-7

[Article by Deng Honghai [6722 1347 3189], Technical Economics Institute, Chinese Academy of Social Sciences: "Theory and Methods of Readjustment of the Agricultural Production Structure"]

[Text] Rationalization of the structure of agricultural production is a major task in the current readjustment of the national economy. In recent years, the work of readjusting the structure of China's agricultural production has achieved initial success. However, as a result of longterm inattention to the study of agriculture from the angle of its structure, the foundation for research work on its structure is weak, and in both theory and methods for readjustment of the agricultural production structure, four problems still exist today. One is that the concept of agricultural production structure is still limited to economic description; it has not risen to the category of a precise science. Second is that only the proportion of the five industries [agriculture, forestry, animal husbandry, sideline occupations, and fisheries] is considered and systematic analysis and overall balance of the overall structure of agricultural production is ignored. Third, rationality of the structure is evaluated only in terms of the proportional size of the farming industry rather than in terms of the structure's overall effectiveness. Four, qualitative and quantitative analysis of the structure of agricultural production in each area is lacking, and no optimum structural plans are presented. As a result, a set of scientific theories and methods are urgently needed for systematic study of the structure of agricultural production, so that readjustment of agriculture everywhere can be genuinely carried out to get the optimum structure for local conditions. Furthermore, systematic study of the structure of agricultural production requires, first of all, a systematic understanding of agricultural production itself.

1. Agricultural Production is a Complex System Formed of a Combination of an Agricultural Ecological System, an Agricultural Technical System, and an Agricultural Economic System.

One essential characteristic of agricultural production that differs from the industrial and other sectors lies in certain agricultural production not only using a definite ecological system as its environment, but also that a definite ecological system is its means of production, i.e. agriculture always uses a definite ecological system to conduct material production. This system, which uses the photosynthesis of green plants in a definite ecological system to produce organic products, forms a definite type of agro-ecological system. Within this system, the amount of organic matter that plants fix and form from solar energy constitutes this system's primary output or biological output. The herbivorous animals that depend on plants for nourishment constitute this system's secondary output. Carnivorous animals that use herbivorous animals to live constitute this system's tertiary output. Yet other carnivorous animals that use these carnivorous animals to live constitute the quarternary and quintenary output. Any output provided for the consumption of mankind in the biological output of these levels constitutes economic output. After mankind consumes these economic outputs in production or in daily life, he breaks the original balance of this ecological system, some of the energy and material taken away not being restored to the system. This requires that people use farm labor to put in economic energy and economic material (the energy and material that can be obtained only through labor) to make up the shortfall so as to maintain the energy circulation and material cycle of this system. Moreover, agricultural labor is always carried out by using definite technical systems within a definite economic system. Consequently, for every period of energy flow and material cycling in the agricultural ecological system, people have to put economic energy and economic materials into this agricultural ecological system from a definite agricultural economic system through a corresponding agricultural technical system, and take economic goods from the energy and materials put out by this agricultural ecological system. Agricultural preproduction is carried on through a process of mutual exchange of economic energy and economic material for natural energy and natural material through the agricultural technical system of the agricultural economic system. From this may be seen that any agricultural production must be a complex system that combines a definite agricultural economic system, an agricultural technical system, and an agricultural ecological system.

This essential characteristic of agricultural production, and this special position of the agricultural ecological system in agricultural had not been consciously understood by mankind for a long historical period. Ever since the industrialization of agriculture in developed countries, people have been accustomed to regarding agriculture from the same point of view that they regard industry, looking only at its economic system and technical system and ignoring its ecological system and the technical system in the modernization of agriculture, but did not devote attention to improving benefits from the ecological system. As a result they were repeatedly punished by ecological laws, sustained losses and setbacks time after time, and only after the worldwide ecological crisis and energy crisis appeared did these advanced countries have no choice but to examine their already developed agriculture in terms of a combination of the economic, the technical, and the ecological in an effort to explore a new agricultural model combining the economic, the technical, and the ecological. This was an instance in which natural laws and economic laws forced people to regard the mutual role of the three systems as an organic whole. In the course of the readjustment of China's agriculture, we should absorb the historacal experiences and lessons of world development of agriculture, respect the objective fact of agricultural production being formed from three sub-systems, consciously regard the mutual role of these three sub-systems as an organic whole, and make a highly comprehensive assessment of the structure of agriculture everywhere in terms of a combination of these three sub-systems. With the goal of improving the overall effectiveness of these three sub-systems, we should determine to readjust the structure of agricultural production everywhere to make it a certain kind of structure, thereby placing readjustment of China's agriculture on a scientific path. If we do not, we will sustain the merciless punishment of objective laws, and after being punished, we will still have to understand agricultural production in this way.

Actually, the classical works of Marxism long ago expounded such a situation in agricultural production. Marx said, "No matter the special social nature of the process of economic reproduction, within this sector (agriculture), it is always intertwined with a natural reproduction process." ("Complete Works of Marx and Engels," Vol 24 pp 398-399, Renmin Chubanshe, 1972.) The economic reproduction process spoken of here means the transformation of labor the circulation of funds, and the economic material and economic energy cycles is the agricultural economic system. The basic functional unit in economic reproduction is a definite agricultural economic system. The natural reproduction process spoken of here means the energy transformation and material cycle in the agricultural ecological system. The basic functional unit of natural reproduction is a definite agricultural ecological system. The intertwining of these two reproduction processes means a series of energy and material transformations in the agricultural economic system through the agricultural technical system and the agricultural ecological system. The economic energy and economic material of the agricultural economic system is transformed through labor into physical energy and chemical material in the agricultural technical system. Within the agricultural ecological system, the agricultural technical system's physical energy and chemical material is transformed into biological energy and biological material. These material products of the agricultural ecological system are transformed in turn by the agricultural technical system into economic products and sent into the economic system. Even though ecological theory had not been formed at that time and Marx was unable to make a systematic analysis of the natural reproduction process in the same way he had done for the economic reproduction process; nevertheless, Marx's brilliant exposition of the nature of agricultural production provided us a theoretical basis for systematic understanding of agricultural production. Today when ecological science and systems science are flourishing, by following Marx's line of thinking for further penetrating understanding of agriculture in order to make a further systematic analysis of agricultural production, and to define agricultural production in terms of a complex system formed of an agricultural economic system, an agricultural technical system, and an agricultural ecological system permits us to raise the concept of agricultural production from the empirical description stage to the category of an exact science. Marx said that only when science successfully applied applied mathematics could it reach the point of perfection. ("Complete Works of Marx and Engels," Second Russian Language Edition, Vol 33, p 72) By using a systematic concept to understand agriculture and to define agricultural production in terms of a complex system of three sub-systems, it is possible to use systems engineering techniques to describe agricultural production mathematically, and to analyze systematically, both qualitatively and quantatively and ever more concretely, agricultural production everywhere so that we can both ever more accurately master agricultural production in terms of its qualitative forms and within its quantative limits to make agricultural management increasingly rational and scientific.

2. The Structure of Agricultural Production Is a Three Dimensional Network Formed by the Intertwining of the Agricultural Economic Structure, the Agricultural Technical Structure, and the Agricultural Ecological Structure

The agricultural production structure that is seen by looking at agricultural production using systematic concepts is not the five industry structure of farming, forestry, animal husbandry, sideline occupations, and fisheries, but is rather a three dimensional network structure formed by the intertwining of the agricultural economic structure, the agricultural technical structure, and the agricultural ecological structure in which the agricultural economic structure, the agricultural technical structure, and the agricultural ecological structure are first order structures of agricultural production. These three kinds of first order structures are divided, in turn, into various second order structures. The agricultural economic structure includes: 1. The economic component structure, which in China's socialist agriculture is a structure in which the state economy, the enterprise economy, and the household privately retained economy are combined. 2. The production, distribution, exchange, and consumption structures within the economic reproduction process. 3. The economic sector structure, a structure formed from a combination of the farming, forestry, animal husbandry, sideline occupation, and fishery sectors. 4. The economic regional structure, by which is meant the spatial structure and regional distribution of agricultural production. The agricultural technical structure includes: 1. A structure formed from physical techniques, chemical techniques, and biological techniques. 2. A structure formed from a combination of primitive techniques, traditional techniques, transitional techniques, and modern techniques. 3. The product input and output structure, that is the direct consumption coefficient matrix. The agricultural ecological structure includes: 1. A structure composed of diverse agricultural ecological systems (including forests, grasslands, farmlands, waters, residential areas, and garden systems) in a given area. 2. A biological community structure (plants, animals, and micro-organisms) within individual agricultural ecosystems. 3. The energy balance, moisture balance, and nutrient balance within regional ecosystems and individual agricultural ecosystems. These second order structures are formed from diverse third order structures. These include the balance between income and expenditures within the national, the enterprise, and the household economies; the proportion between consumption and accumulation in distributions; the proportion of various crops in agriculture in a narrow sense (farming), the livestock and poultry structure within the animal husbandry industry; the proportion of the five kinds of forests and the proportion of forest crops within the forestry industry, as well as the proportional amount of felling, processing, and afforestation; the enterprise type structure, the product structure, and the production and marketing structure within industrial sideline industries; the proportional amount of catching and breeding and the proportion of power machines, traditional machines, and work machines within physical techniques; the structure formed from various kinds of techniques in each technology; and the colony structure within various biological communities. These third order structures are in turn composed of fourth order and even greater order structures. Such an order by order breakdown can be continued endlessly, and with each breakdown by order, our analysis of the structure of agricultural production deepens a little. Through such a step by step deepening of understanding, our understanding of the structure of agricultural production becomes increasingly concrete. Not only can the various structures of each order in the three sub-systems of agricultural production be broken down (or analyzed) qualitatively, but quantative formulations may also be made. No matter the kind of system, the order, or the aspect of a structure, it can be depicted in energy terms, or expressed in terms of amount of labor consumption, amount of value, amount of currency, amounts of various materials, amounts of time, and amounts of space. Some structures in the agricultural ecosystem cannot be described in terms of conversions to amounts of currency. In addition, a specific structure always corresponds to a specific function. The size of function reflects the degree of rationality of the structure. Consequently, all structures may be described in terms of their function.

In such a systematic view of the structure of agricultural production in which the structure and function of each aspect of each order of each agricultural ecosystem in all kinds of agricultural economic systems, agricultural technical systems, and agricultural ecosystems are organically combined in a total and comprehensive system shows the existence of an inherent relationship between all kinds of microcosmic structures and functions, and between the structure and function of each microcosmic structure and function and the macrocosmic structure and function of agricultural production as a whole. Thus, not only are we able to use the telescope of large scale grain production in large scale agriculture for the study of the structure of agriculture in breadth, and not only are we able to use the microscope of observation of the microcosmic structure for the study of the agricultural structure in depth, but we are also able to analyze systematically the entire structure of agricultural production. If we formulate and quantify one by one the various individual structures and functions of a certain order and determine the quantative relationship of these structures and functions, it is possible to set up an agricultural production model, and electronic computers can rapidly and accurately calculate on the basis of different inputs (readjustment programs) corresponding outputs (results, benefits, and effects). This can provide a scientific basis for selection of the optimum readjustment program and rationalization of the structure.

More importantly, such a systematic understanding of the structure of agricultural production greatly enriches in breadth and in depth the content of the work of readjusting the structure of agricultural production, so that the structural readjustment work is not just a matter of the proportions of the five industries, but rather really proceeds from the realities of the structure of agricultural production in each individual area, uncovers existing irrationalities through a seeking for truth in facts, and permits readjustment by suiting the medicine to the illness. Within the existing agricultural production structure of individual places, irrationalities are not necessarily or not only in the structure of the five industries, but may also appear in the economic component structure, the agricultural ecological structure, and agricultural technical structure, or in the agricultural economic reproduction structure. They may also occur in the regional structure. Whatever the irrationality, it can only be determined through systematic analysis of the local agricultural production structure.

To conduct a readjustment of the structure of the five industries throughout the country using identical proportions everywhere in a stereotyped way is the same as the many "arbitrary uniformity" methods formerly applied to the country's industrial work in that they contravene the principle of "adaptation of general methods to local situations" in agriculture. Natural and economic conditions differ from place to place, so there can be no identical agricultural ecological structure, agricultural technical structure, and agricultural economic structure, and thus there can be no identical proportions of the five industries that is suited to its own individual conditions, and this optimum proportion can only be found in the overall relationships of the local agricultural production structure.

Looked at in terms of actual circumstances obtained in the agricultural production systems throughout the country, readjustment of the structure of agricultural production at the present stage requires attention principally to work in the following regards: (1) Each area has to find the optimum model for the constituent structure of its agricultural economy (the three tiered state, enterprise, and household economy) suited to the local area so that the present rural production responsibility systems can be improved. (2) Each area has to find the optimum agricultural ecological structure suited to the local area and use this optimum agricultural ecological structure to administer and manage the existing agricultural ecological structure, to improve and restructure the existing agricultural agricultural ecosystem, and to renovate and rebuild a highly efficient agricultural ecosystem. (3) Each area has to find the "suitable agricultural technical system" for the locale, so that China's level of intensivity in agriculture will be constantly increased while at the same time occasioning no "incremental reductions in remuneration." (4) All areas should find the agricultural economic reproduction structure suited to local conditions for most effective integration of agriculture, industry, and commerce. (5) Each area should find the optimum agricultural regional structure for the area, and combine readjustment of local crop patterns, departmental structures, and ecological structures to make the most of regional advantages of local agriculture. (6) Each area should find the optimum local departmental structure and input-output structure so that agricultural production will be able to satisfy to the maximum extent possible the needs of society with limited consumption. Naturally the work to be done in these several regards cannot be done in a disjointed way, but must proceed from the all-around benefits derived from agricultural production as a whole with planning being done in an overall way and carried out in a coordinated way.

3. The Criterion For Rationality of the Agricultural Production Structure Is the Overall Effectiveness of the Agricultural Technical Structure and the Agricultural Ecological Structure

In using systems concepts to look at the structure of agricultural production, one cannot use the proportions of the five industries in agriculturally developed countries or the proportional size of the farming industry as criteria; for the rationality of the production structure, but rather one can only use as a criterion the overall effectiveness of the ecological structure, the technical structure, and the economic structure in agricultural production.

It may be seen from the foregoing analysis of the structure of agricultural production that the structure of the five industries cannot encompass the total agricultural production structure. It is but one aspect of the agricultural production structure. If we divorce ourselves from the ecological structure of agriculture, the technical structure of agriculture, and other aspects of the economic structure of agriculture and isolatedly and lopsidedly look only at the structure of the five industries, it will be impossible to make a comprehensive and realistic evaluation of the structure of agricultural production. The structure of the five industries is determined by the natural conditions and economic conditions for agricultural production, and conditions in individual countries and individual areas differ in thousands upon thousands of ways, so the structure of the five industries cannot be the same. Were a stereotyped structure for the five industries to be used throughout the country and throughout the world, the structure would not be adjusted for the better but only for the worse. The structure of the five industries in agriculturally developed countries suits the natural and economic conditions of these countries; it is suited to their agricultural ecological structures, agricultural technical structures and agricultural economic structures. Their agricultural technical systems are founded on petroleum, and the mineral energy currently being inputed to the agricultural ecosystem is greater than the output of food energy. In reality, more than 1 jin of petroleum is exchanged for 1 jin of grain. China's needs for food and other agricultural products are much greater than in these countries. Were China to copy their agricultural economic systems, the amount of petroleum annually required by the country's agriculture would also be greater than theirs, and where would such a large amount of petroleum come from? Even were a source available, how could we afford to use it? In addition, this kind of technical system is suited only to large area growing of single kinds of crops using large amounts of chemical fertilizers, herbicides and pesticides. Expansion of this technical system would lead to soil exhaustion, environmental pollution, and destruction of the ecological balance. We cannot copy such an agricultural technical structure and agricultural ecological structure. Inasmuch as China's agriculture cannot copy these developed agricultural technical structures and agricultural ecological structures, the structure of the five industries in China's agriculture can likewise not be like theirs. To have our country emulate developed countries in the proportions of the five industries of agriculture uncaring of China's realities is extraordinarily dangerous. It is also necessary to realize that the proportions of these five industries and of the farming industry are relative figures, and the specifications determined for the five industries are also not identical. Separation from absolute figures and other related circumstances and looking only at these relative figures may frequently lead to ridiculous actions.

Use of the proportions of the five industries will not work, but will use of five basic requirements to measure and evaluate the agricultural production structure of individual places work? The question is whether these five basic requirements will be in accordance with the basic laws of socialist economy, make the most of natural resources, constantly maintain the harmony and balance of all sectors, obtain optimum economic benefits, and help the application of advanced techniques. (See "Readjustment of the Structure of Agriculture and Development of Agricultural Production," published in "Agricultural Economy Reference Materials" by the Agricultural Economics Institute of the Chinese Academy of Agricultural Sciences, Issue No 8, 1981). This article says that any technical economic activity has to follow certain principles and that direct use of these principles to evaluate any specific technical economic activity will not work. All technical economic activities have their own individual specific results. Evaluation of these specific results requires making specialized standards, specialized criteria systems, and specialized evaluation methods out of these principles. Evaluation of the rationality of agricultural production structures is also like this. The concrete manifestation of their rationality is various specifically intended results. Consequently, they require specialized criteria systems, and specialized evaluation methods.

Inasmuch as the structure of agricultural production is a multi-layered structure composed of the agricultural economic structure, the agricultural technical structure, and the agricultural ecological structure, an evaluation of the rationality of the agricultural production structure requires an all around evaluation of the rationality of various individual structures in individual aspects of individual orders in the systems making up the agricultural production structure. For every specific structure there is always a specific corresponding function, and a specific function naturally produces a corresponding benefit. Consequently the criterion for evaluating the rationality of a structure has to be the benefits of this structure. On the basis of the various aspects of the individual orders of this overall system in agricultural production, the agricultural economic structure may be divided in terms of function into an agricultural technical structure and an agricultural ecological structure. Therefore, standards for evaluation of the rationality of the agricultural production structure must be the overall benefits provided by these economic structures, technical structures, and ecological structures. These overall benefits correspond to the sum total of agricultural economic benefits, agricultural technical benefits, and agricultural ecological benefits. Comprehensive evaluation of the three kinds of benefits from these three kinds of structures permit us to make a comprehensively systematic and accurate evaluation of the rationality of the agricultural production structure everywhere, to find the irrational links, and to set a course for readjustment of the structure.

Any evaluation of the rationality of an agricultural production structure must be a comprehensive evaluation of agricultural economic benefits, agricultural technical benefits, and agricultural ecological benefits, and not just an evaluation of economic benefits. A dialectical relationship exists among economic benefits, technical benefits, and ecological benefits in agricultural production, and there is both a mutual unity and a mutual contradiction among them. In a situation wherein the existing techniques of developed countries are taken to be symbols of agricultural modernization with blind pursuit of the advanced techniques of these countries, and use of the quantities of machine power, chemical fertilizers, and pesticides as are used per unit of area in these countries so that the speed of increase of things that converted from mineral energy greatly exceeds the speed of increase in agricultural products, and the speed of increase in material expenditures greatly exceeds the speed of increase in output, results in increased output with no increase in earnings or even reduced earnings, and ever decreasing economic benefits from these advanced techniques. This is a common manifestation of the contradictory unity of technical benefits and economic benefits. In circumstances of a plundering style of operations in agriculture, blind pursuit of momentary economic advantage, much use and little nourishment, and taking much but restoring little to cultivated land; reckless cutting and denudation of forests with much cutting and little afforestation so that the amount of felling is greater than the amount of growth; overgrazing of grasslands that are only used but not nurtured; and overfishing in the fishing industry all lead to deterioration of the ecological environment and steady decline in resources that plunges agricultural production into a vicious cycle. This is a general manifestation of the contradictory unity of economic benefits and ecological benefits. Countless lessons of history of the past and present, from China and from abroad have taught us that when evaluating and readjusting the structure of agricultural production, there can be no proceeding in isolation from a single benefit, but rather one must proceed from the heights of a combination of economic benefits, technical benefits, and ecological benefits. It is particularly important not to divorce oneself from ecological benefits because any evaluation or readjustment that is divorced from ecological benefits will be deficient and narrow. In long range terms and overall terms, such an evaluation and readjustment will be bound to be unreliable.

SURVEY REPORT ON PLANNED ECONOMY ISSUED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 8, 1982 pp 63-64

[Article: "Survey on 'Agriculture Should Also Institute Taking the Planned Economy as the Key Link With Market Regulation Being Supplementary' Carried Out Jointly by the Chinese Academy of Social Sciences and Eight Provinces"]

[Text] Discussion and exchanges took place between 25 and 30 June about a survey on "agriculture should also institute taking the planned economy as the key link with market regulation being supplementary." This survey, the drafting of an outline for which had begun in late March, was carried out during April and May. It had been jointly organized by the Economics Institute of the Chinese Academy of Social Sciences and the economic research institutes (or offices) of the social science academies (or institutes) of the eight provinces of Guangdong, Zhejiang, Jiangsu, Anhui, Shandong, Sichuan, Gansu, and Liaoning. Also invited to participate in the survey and discussions was a total of more than 50 people from the Institute of Economics of the State Planning Commission, and both theoreticians and people engaged in practical work from departments concerned and from institutions of higher learning in the eight provinces. The survey report presented to the discussion meeting consisted of 22 pages containing about 180,000 characters. During the second half of the year, several special topics will continue to be surveyed in depth.

The content of this survey was divided into two main parts. One was on the management and organization of agricultural planning. The other was on problems in planning and management in the rural commodity flow area. Comrades who participated in the survey and discussions believe that with the rapid development of agricultural production, new changes have taken place in both the structure of the rural economy and farm crop patterns, and that the commodity flow area has begun to come alive. In order to adjust to the diverse kinds of responsibility systems in agricultural production, to the rural businesses' economically diversified components and methods of economic diversification, and to the multiple flow channels and multiple forms of pricing in urban and rural markets, a new road has to be explored for further strengthening planning of the direction of agriculture, to insure that the rural economy is lively without being chaotic, and that it is regulated without being stifled. In the discussion, everybody stressed the following several ideas for reform: (1) A good job of overall balance. It is organization and realization of an overall balance in the national economy that the planned economy has to solve. Agriculture is a basic sector in the national economy, and agricultural planning must first of all break through its narrowness in considering only production and procurement to formulate unified plans for production, supply, and marketing. These unified plans also have to be placed within the context of total national economic balance for genuine solution to agriculture's "fundamental" position in the formulation of priorities and norm systems in plans. (2) A firm grip on grain production. Correct handling of the relationship between grain crops and economic crops has long been at the center of the planning of agrcultural production in China. Now various actions have to be taken to stabilize the area sown to grain, to encourage increases in yields per unit of area, and to curb the tendency toward a certain blind development of economic crops. Increase in grain output depends primarily on the tapping of potential from medium and low yield areas, yet consolidation of old commodity grain bases now continues to be of extremely important significance. (3) Readjustment of economic policies. Balanced economic benefits are a major condition for implementation of state plans. Only by solving the problem of overly low efficiency in grain production will it be possible to reduce their growing area effectively. When drawing up state plans, it will be necessary additionally to give consideration to the application of levers such as prices, taxes, loans and public finance, as well as distributions of benefits within the collective economy to readjust economic benefits in all fields concerned (including production, processing, allocation, and marketing of farm products.) Procurement prices paid for farm products require stabilization now; consequently, study is urgently required on improvements in state procurement (or purchase) price base figures, increased prices for excess procurement, and bonus policies, as well as ways of supplying materials used in agriculture in order to readjust earnings between different varieties of grain crops and economic crops and between one economic crop and another, and among farming, forestry, animal husbandry, and fishing to promote proportional, coordinated development of each kind of production. Last year after Zhejiang Province announced limitations on additional prices paid for excess procurement, the structure of the winter-sown area underwent very great change. (4) Commune and brigade enterprises should be made a part of state plans. When summarizing the relationship between commune and brigade enterprises and agriculture, Jiangsu Province pointed out that even though commune and brigade enterprises have an extremely important role in supporting agriculture and in advancing development of the rural economy, a tendency really exists among them to assault state plans. Consequently, it is necessary to make strengthening of planning and management of commune and brigade enterprises a topic for study in the planned agricultural economy. Nanhai County in Guangdong Province used various means such as making contracting an indirect part of state plans, linkage to state-owned plants, and processing of materials brought in from elsewhere to set commune and brigade enterprises on the track of state plans. This achieved a certain amount of success. (5) Perfection of plan management structure. In formulating agricultural production, supply, and marketing plans today, the situation of dispersal of forces with no mutual dovetailing cries out for change; for central government category 1, strengthening of the function of the the overall balance structure is required. County planning departments are the foundation for bringing about all around balance, and they are also the bond that ties together state plans and producers. Today, however, they are extremely weak and require strengthening with all possible speed. Grassroots political power--the key to carrying out state plans lies in how well communes and brigades are organized. In areas practicing primarily the form of "double contracting" [contracting fixed output quotas and responsibility for specific work tasks to households], perfection of grassroots organization and strengthening of their economic function is particularly important. The nature of command and guidance for quota management has no practical significance below the county level. Shandong comrades believe that "production is the foundation, and procurement is the key; contracts are the guarantee, and prices are the nucleus." (6) Strengthening and bringing into play the main channels in the rural commodity flow area. The position of state-owned business as major channels must be affirmed, and full use made of their leading role among many channels of many kinds. Sichuan created four models in pilot projects for reform of its supply and marketing cooperative system as follows: (1) Merger of commune businesses with supply and marketing cooperatives; (2) transfer to communes of all supply and marketing cooperatives; (3) Practice by supply and marketing coopertives and related units of decentralized joint ventures; (4) Joint ventures by grassroots cooperatives and production teams. Comrades who made the survey believe the third model to be a rather good one. At pilot projects for reform of grassroots cooperative organization in Jiangsu County in Jiangsu Province, full accounting for shares, enlargement of shares, honoring of bonus distributions, establishment of supervisory councils, changes in operating styles and methods and genuine solution to problems of the masses in "difficulties in buying," and "difficulties in selling" produced very great benefits in revival of the "three natures."

At the discussion, everybody believed that this kind of combined survey was a useful effort whose benefits were as follows: (1) Cooperation vertically and laterally for a concerted attack on problems. Inasmuch as the topics covered by the survey were very large and touched on a very broad area, it could not have been easily completed within a short period of time by the efforts of several people in a single unit. In future, combinations of comrades in pertinent provincial and municipal departments to carry out surveys of fairly great policy importance is required. Research organizations can proceed from this foundation to undertake systematic academic study. (2) Individual characteristics of key points and whole areas. Units participating in the survey used their commonly drafted outline in combination with the characteristics of local areas to select one or two key counties and key problems (or sometimes key products) on which to conduct a survey that probed fairly deeply, and surveyed and reported on the characteristics of each county. This was followed by the rendering of an overall analysis of definite scope to locate things in the nature of laws. Comrades participating in the survey believe that in future continuous observation and study of such points should be maintained so that understandings will be closer to realities. (3) In a situation of heavy responsibility, few personnel, and short time, results can be obtained fairly rapidly and fairly well.

'BEIJING REVIEW' ON GRAIN PRODUCTION, IMPORTS

HK151016 Beijing BEIJING REVIEW in English No 25, 11 Oct 82 pp 3-4

[Article by economic editor Jin Qi: "Grain and Cash Crops"]

[Text] Are Chinese peasants today so enthusiastic about growing high income cash crops that the country will need to prolong its dependence on grain imports?

Over the last few years China has adopted a series of flexible rural economic policies, such as expanding the peasants' decision-making power in farm production. It also has corrected a previous one-sided emphasis on grain production. As a result, farm production has greatly improved, with the output of cash crops rising measurably.

The total agricultural output value in 1981 was 17.9 percent more than in 1978 (calculated according to 1970 constant prices). Of this, the output of grain rose by 6.7 percent and that of cotton, oil-bearing crops and beetroot increased by 37, 95.6 and 135.4 percent, respectively.

The rapid increases in the output of cash crops can be partially attributed to the liberating effects of current policies on these crops. However, irrational pricing is more significant. Left behind by history, arbitrary pricing practices enable people to profit more from cash crops than from grain. Consequently, the acreage sown to grain in 1981 was reduced by 4.3 percent as compared with that in 1979. This tendency has aroused the concern of the government.

In an effort to stabilize the grain acreage and encourage continued increases in per-unit grain output, the state has strengthened planning and administrative intervention. In addition, other economic measures are being considered to bridge the profit gap between the production of marketable grain and the production of cash crops. To name a few: The amount of grain purchased by the state in grain-producing areas at fixed parity (thus, lower prices) will not be increased, and the amount of grain in excess of the prescribed amount purchased at fixed parity will be purchased by the state at preferential negotiated prices; grain-growers will be accorded preferential treatment in the supply of scarce industrial goods needed in production and daily life, such as chemical fertilizers, certain farm tools and machines and bicycles;

and the profit for cash crops that encroach on the land sown to grain will be appropriately reduced.

It is true that China has increased grain imports in the last few years. But this stems from a too rapid growth in grain consumption rather than a decrease in domestic supplies (as a matter of fact, they are growing). Grain sales in 1981 were 27 percent higher than in 1979. The population growth accounts for some of the increased grain consumption. But the main reason is China's ongoing effort to develop the foodstuff and fodder industries. China imports only a small amount of grain, some of which is used to increase the varieties. Deducting the exports from the imports, the net grain imported in 1981 (the year with the largest amount of imported grain) was only 4 percent of the nation's total grain output.

A populous country like ours cannot depend on imported grain. Our consistent policy has been to rely principally on domestic grain production, and to use the international market only to adjust our deficiencies and surpluses. This policy, I think, will never be changed.

PROPOSAL ON DEVELOPMENT OF RURAL FOOD INDUSTRIES AIRED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese
No 8, 1982, pp 47-50

[Article by Chen Yueru [7115 2588 1172], Agricultural Economics Institute, Chinese Academy of Agricultural Sciences: "Brief Discussion of Development of Commune and Brigade Food Industries"]

[Text] Food industries are processing industries using agricultural by-products as raw materials. Development of food industries requires, first of all, agricultural production to provide them with raw materials. We must focus on all around use of all the resources of China's soil to provide ample raw materials for the food industry so that the food industry can develop. Only in this way will it be possible gradually to change the diet and improve the nutrient value of food. Development of the food industry can also energize development of rural economic diversification and commune member household sideline occupations to bring a fairly great change in China's longstanding unitary production structure in which grain has been paramount, establish a good agricultural situation, and bring about a benevolent cycle, thereby further advancing the all-around development of agricultural production. Therefore, in the strategic task of changing the structure of China's agriculture and the structure of food products, development of the food industry holds extremely important significance. In addition, development of the food industry means development of consumer goods production, which not only enlivens markets and enriches the lives of the people for satisfaction of people's requirements for diverse kinds of foods following increase in the people's purchasing power, but also makes the structure of the national economy become more equitable.

Significance of development of the food industry is extremely great, yet we have long neglected development of the food industry. In 1979, gross output value of the country's food industry (including commune and brigade food industries) amounted to only 10.3 percent of the gross output value of the country's industry and 7.6 percent of the gross output value of the country's industrial and agricultural output value. This included an output value from commune and brigade food industries of only 100 million yuan, which amounted to only 4 percent of the gross output value of the country's food industry. An extremely large portion of this was first echelon processing of products, and 80 percent of it was production for the use of communes and brigades themselves. Between 1978 and 1980, food industry as a proportion of commune and brigade enterprises was 5.6 and 7 percent respectively. Employees numbered only 2.5 percent of the total number of employees in commune and brigade enterprises. Among export products, 76 percent were agricultural product raw materials, with processed foods amounting to only 24 percent. Output value of processed agricultural products for economically developed countries is usually double the output value of agriculture, but in China the output value of processed agricultural goods is, conversely, lower than the output value of agriculture. China's food industry is backward and not commensurate with the needs of daily life for a 1 billion population and development of agricultural economic diversification. For example, food supply for urban industries is insufficient, varieties are few, and quality is poor; food supplies for rural industries are even more monotonous. Particularly in out-of-the-way mountain regions and in border regions where there is virtual no food supply for industries, and where the soy sauce, vinegar, and such condiments needed by the people in their daily lives require a round trip of several tens of li to the county seat. Because of the lack of development of the food industry, on the one hand inadequate supply of food to industries has occured while, on the other hand, some raw materials cannot be sold. For example, in many places it is difficult to sell hogs or rabbits; in mountain regions, large quantities of indigenous products or resources that grow wild rot where they are; in areas where their production is concentrated, large quantities of potatoes mold and rot. Every year 20 percent of fresh fruit rots, and during 1980 20,000 tons of citrus rotted in Sichuan. During the past 2 years output of cottonseed and rapeseed has increased tremendously, but because of a shortage of processing capacity they could not be processed promptly and their oil output rate declined. In pastoral areas, cows milk and goats milk is fed to hogs. Annually between 300,000 and 400,000 tons, or 10 percent of total output of aquatic products spoil. Fish in hand does not reach the mouth. Producers of raw materials incur losses because of this, which dampens peasant enthusiasm and has led in the past to ups and downs in the production of agricultural products, and slow development of economic diversification.

From this may be seen that agricultural economic diversification and the food industry are both mutually restricting and mutually promoting, objectively requiring a linking of the farming, breeding, and processing industries. Moreover, development of commune and brigade food industries is an important way in which to promote the linking of the farming, breeding, and processing industries. Operation of processing industries in places that produce raw materials and hastening construction of raw materials bases to form a continuous process of farming, breeding, and processing is consistent with an orientation of comprehensive farming, industrial, and commercial operations.

The role of commune and brigade food industries in promoting agricultural production is also manifested in the following several main ways:

1. Commune and brigade food industries can more effectively use the wastes left over at the time of production for livestock feed or for direct use in fertilizing the soil, thereby returning natural materials to nature. For example, the Xinqiao Commune Food Plant in Songjiang County, Shanghai annually

processes more than 18,200 tons of frozen chicken for export and is able to supply 15 tons of chicken manure monthly for direct use in fertilizing the soil. It can provide a total of 1,370 tons of chicken intestines containing manure over a 10 year period for supply to every hog raising farm in the commune to feed their hogs, the hog manure being used as fertilizer for development of agricultural production. Baoshan Commune in Panshi County, Jilin Province uses bald hills and barren slopes to grow fruit trees, which provide raw materials for the commune canning plant, leftover skins, residues, and slop being fed to livestock, the livestock manure providing fertilizer to the fruit trees, in turn. This use of farming to provide raw materials for the processing industry, and the processing industry to give impetus to the breeding industry, and the breeding industry promoting, in turn, the farming industry in a benevolent cycle is something that food processing industries far removed from raw material production areas cannot do. When farm products are assembled in cities for processing, they may cause urban pollution and put and end to the balanced mutual exchange of nutrients between the natural world and mankind. As Marx noted, "The integral part of the soil consumed by man in the form of clothing and food cannot be returned to the soil, thereby damaging the perpetual natural condition of the soil's enduring fertility." ("Complete Works of Marx and Engels" Vol 23 p 552).

2. Commune and brigade food industries can open production avenues for agriculture and take care of surplus workforces. Today there is a general 30 percent surplus of workforces in China's rural villages, "If these people who have been squeezed out of agriculture are not to remain out of work or be forced to congregate in cities, it is necessary that they engage in industrial labor in rural villages." ("Complete Works of Marx and Engels," Vol 19, p 369). The food industry is a labor intensive industry that can provide for a substantially greater workforce for the same amount of capital. Food industries energize economic diversification and development of commune member household sideline occupations, promote progress in production in depth and breadth, and provide an outlet for surplus workforces. Were rural food industries properly concentrated in rural market towns where communes exist, they would give impetus to small city and town construction, and still greater numbers of the surplus workforce could be taken care of. Rough calculations show that if every one of the rural market towns where more than 50,000 communes in the country are currently located were able to absorb an average of 2,000 people, it would be possible to provide employment opportunities for more than 100 million surplus rural workforces, and they would not be forced to congregate in cities.

It is characteristic of agricultural production that the process of natural reproduction and the process of economic reproduction are intertwined. The production period is much greater than the labor period, and there are separate slack and busy seasons in agriculture; however, inasmuch as the busy seasons and the slack seasons differ in industrial production and agricultural production, the same workforces may be switched back and forth into agricultural and industrial production. Workforces can be transferred to economic diversification tasks of a seasonal nature so that the workforce is fully and equitably used, producing more products for society.

3. Commune and brigade food industries can make full use of resources. Commune and brigade food industry local procurement of materials and local processing favors use of dispersed odd bits and pieces of resources, and other resources, discarded resources, and wild growing resources that large industries do not use can be comprehensively used, and new uses for foodstuff raw materials can be found. Take tuber crops such as potatoes, yams, and cassava, for example. In addition to processing into starch and noodles, they may be processed into citric acid, alcohol, lactic acid, glucose syrup, and amino acids. If tuber starches and cornstarch are further processed, maltose, glucose, and fructose can be produced. Fructose can be produced at lower cost than cane sugar; it is sweeter; and it has wider uses. Through processing, the usefulness of tuber raw materials is greatly heightened. Yet another example is the cake residues that were formerly used directly for livestock feed or fertilizer, from which concentrated protein and separated [3863 2649] proteins may be extracted through deep processing. From cottonseed cake cotton phenol [2758 1568] (a protein) can be extracted. Cottonseed husks, corn cobs, wood shavings, and bagasse, which had been used as fuel or processed as waste materials, have now begun to be used in rural villages to produce edible fungus. Areas that produce large dates use rotten dates for processing into date essence [2764 4737] a perfume indispensable to the manufacture of cigarettes. Examples in the realm of food industry use of plentiful wild growing resources include use by Xiangtun Commune in Dexing County, Jiangxi Province of vitex cannibfolia which grows all over the local mountain region, and which can be processed to produce vitex cannibfolia oil capsules (for the treatment of chronic bronchitis), which is marketed widely in all of the countries of Southeast Asia. Henan, Hubei, and Sichuan provinces used actinidia berries for processing into preserved fruit, liqueur, and fruit juice to take advantage of local natural resources, to expand use of raw materials, and to promote development of resources.

4. Development of commune and brigade food industries is a good way in which to promote the specialization of agriculture and to build raw materials bases. Following institution of production responsibility systems in agriculture, specialized teams, specialized households, and specialized workers made their appearance. Accompanying development of economic diversification has been the development of food processing industries funded and operated by commune and brigade collectives and by commune members. Storage, cold storage, packaging, and transportation industries associated with the food industry, as well as departments that generate raw materials, provide the means of production, and supply services showed corresponding development. These functions, which had formerly been a part of agriculture, gradually separated from agriculture to become specialized operations with the result that a steady decline occured in that part of farm products and raw materials going directly into consumption, and products of a commodity nature steadily increased, thereby strengthening the reliability of each individual link in the production of end products. Division of labor and division of industries gradually developed, and this inevitably required coordination. Coordination created, in turn, conditions for increased specialization. A look at the freezing plant at Chengguan Commune in Wuqing County, Tianjin shows this plant to have an annual processing capacity of 900 tons, which has led to construction of a raw materials base, as a result, the local chicken raising industry

developed from three production brigades and four chicken farms providing 96,000 chickens in 1971 to 112 production brigades and 145 chicken farms plus more than 1,700 commune member households raising a total of 1,138,000 chickens in 1980. The chicken raising industry sparked the marten raising industry and the rabbit raising industry with the result that the breeding industry throughout the county gradually became regionalized and specialized. Specialization promoted development of commodity agricultural products and commodity exchanges and requiring striking growth in the close linking of transportation and marketing departments. This resulted, in turn, in development toward the direction of a high level of link up with the integration of agriculture, industry, and business for farming, breeding, processing, and marketing. Restructuring of the organization and management of agricultural production gave further impetus to development of the economic diversification of agriculture.

5. Commune and brigade food industries can spark development of household sideline occupations. In areas in which production or work tasks have been contracted to individual households, raw materials for the food industry come primarily from commune member households, and some agricultural production tasks also lend themselves to commune member households. Commune member households use their spare time or supplementary labor forces, and use space in front of or behind their homes, odd bits of wasteland, depressions, or odds and ends of water surfaces to produce raw materials for the food industry. Moreover, the food industry, in turn, opens marketing avenues for commune member household sideline occupation products and removes commune member concern about not being able to sell their products. Food industries also provide for commune member household sideline occupations stud livestock and poultry and mushroom spores, promote scientific farming, scientific raising of animals, and knowledge of scientific management, and provide necessary economic support. For example, formerly commune members in Bocheng Commune, Gaomi County, in Shandong Province had to go through a procurement point set up by the foreign trade sector in order to sell rabbits. From the procurement point, the rabbits went to a grassroots supply and marketing cooperative, and the supply and marketing cooperative transferred them to the County Foreign Trade Bureau, which transferred them to Qingdao for processing. There were numerous procurement unit circulation links, and they attempted to run down quality in order to hold down prices paid and pass on to peasants the increased expenses and losses, with the result that the rabbit raising industry could not develop. Now the commune is running the freezing plants, and in addition to signing contracts with commune member households stipulating the quantity to be sold annually and the bonus system, they have withdrawn 30,000 yuan from plant profits to help hardship households develop household sideline occupations and to provide more than 20,000 tons of fish meal feed to them; they have also sold 60.000 chicks on credit, loaned commune members 3,500 female rabbits for breeding, have printed and distributed books on the raising of livestock and poultry and prevention and control of epidemic diseases, and have sent technical personnel a lecture circuit and to give on-site guidance. They have thus achieved a combination of plant breeding and household raising or household breeding and household raising livestock and poultry, and households raising the three large flocks

(chickens, ducks, and rabbits) number 50 percent of the total. Most households have raised eating (or laying) chickens and rabbits, with the number of specialized households developing to 282 and the number of specialized workers climbing to 4,400. Seven commune households have realized annual net profits of more than 3,000 yuan from the breeding industry. Last year 166,000 head of livestock and poultry of various kinds were raised by commune member households, a 142 percent increase over 1980.

6. Commune and brigade food industries have dovetailed farming, breeding, and processing to raise labor productivity rates, to reduce losses and waste in the circulation process, to reduce the "price scissors," and thereby increase both collective and commune member income. Local processing has brought about mutual cooperation among farming, the breeding industry, and the processing industry for an increase in productivity. Inasmuch as certain agricultural raw materials are large in volume, light in weight, and very full of moisture making them difficult to haul, prone to spoilage, and difficult to store, commune and brigade processing industries immediately instituted processing at the production site so that "commodities rapidly went from one production stage to another production stage or, in other words, the intervening time was shortened for a reduction in the waiting time of intervals between one production stage and another, that is to say, a shortening of the transfer from one production stage to another production stage ("Complete Works of Marx and Engels," Vol 26, p 314) for a reduction in losses and waste, a saving in transportation, and expenses for circulation links. Additional, development of commune and brigade food industries can leave within the farming industry some of the net income created by agriculture that is transferred to the industrial and business sector as a result of the existence of the "price scissors," and increase accumulations of agricultural capital and commune member income.

A look at the role of the aforementioned commune and brigade food industries in promoting agricultural production shows that commune and brigade food industries should be made an important integral part of the acceleration of food industry development nationally. The advantages, the raw materials, and the markets for development of the food industry are in rural villages. Though technical facilities and size of state-owned food industries are rather superior, the advantages to industry conceal the harm done to agriculture. In all the countries of the world with a developed food industry, the focus of development is on rural villages. While assuring supplies of raw materials to large and medium size food industries, we must act step by step to gradually have commune and brigade enterprises process agricultural byproducts that lend themselves to rural processing. Development of the food industry requires that the state, collectives, and individuals go forward together, and most important should be development of the collective economy. There should be both large modern industries, and small workshops that serve commune member lives in a combination of the large, the medium, and the small. Though commune and brigade food industries are rather small and scattered today; nevertheless, in addition to the many advantages these small enterprises possess as discussed in the foregoing, they also hold advantages in adaptation of general methods to local situation, in doing things simply and thriftily, in being flexible and varied, in not requiring state investment, and in not consuming commodity grain.

In order to correctly handle the sources of raw materials for development of food industries by the country, the collective, and individuals, stipulated base figure procurement methods must be instituted for food industry raw materials. All jurisdictions should conscientiously institute the State Council regulations contained in "In Instituting Unified Procurement and Assigned Procurement of Agricultural Byproducts, the State Should Stipulate Base Allotment Figures for Provinces, Municipalities, and Autonomous Regions," and institute them at the grassroots. The setting of base procurement figures is tantamount to setting quotas, and it both assures state-owned processing plant needs for raw materials and provides self-determination to communes and brigades in processing, production, distribution, and marketing to arouse the enthusiasm of peasants for development of production. Looked at in terms of the results in the macro-economy, by doing things this way not only can there be no diminution of state control over things, but rather great increase. Right now 10 provinces have set base procurement figures in varying degrees for agricultural products, and they all reflect this policy's promotion of the development of agricultural production.

Development of the food industry requires giving impetus to economic association, the association solving problems in insufficiency of funds, skills, and raw materials so that individual advantages can be brought into play. Various kinds of joint partnership ventures between industry and farming, farming and business, communes and brigades, brigades and brigades, and among commune members can be used. Deserving of particular attention is joint ventures by production teams, which link in a single body for all-around development production team economic diversification, commune member household sideline occupations, and commune and brigade enterprises, making it possible as well for the peasants to obtain greater material benefits directly from commune and brigade enterprises. Linking of commune and brigade enterprises with state-owned food plants, with production, supply, and marketing being made a part of plan can also carry skills into the countryside and products into cities, and link primary processing in rural villages with secondary processing in cities.

Food industries cut across light industry, grain, foreign trade, business and supply and marketing sectors, so only by proceeding from the situation as a whole, through division of labor and cooperation, and close coordination can the strengths of each be brought into play. Development plans should be formulated at the county level, taking into account both agricultural zoning and equitable distribution of operations. Key products should be developed on the basis of local resources, and a good job should be done of market forecasting and scientific and technical situation reporting to prevent blind action. Commune and brigade enterprises should convert to food processing industries those enterprises that are to be converted in the process of readjustment so as to be able to use existing plant buildings and facilities, and save on investment. Departments concerned and state-owned food plants should arrange for and give support and assistance in equipment, skills, and supply of supplemental materials for development of commune and brigade food industries. In the course of development, commune and brigade food industries should do a good job of enterprise reorganization, and improve administration and management so that they are able to make a contribution to development of economic diversification and commune member household sideline occupations.

PROBLEMS, PROSPECTS IN FEEDING LIVESTOCK EXPLORED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 8, 1982, pp 58-61.

[Article by Animal Husbandry Bureau, Ministry of Agriculture, Animal Husbandry and Fishery: "Some Circumstances Pertaining to Livestock Feed Resources and Development of the Livestock Feed Industry"]

[Text] Livestock feed is the material foundation for development of a livestock industry. Both domestic and foreign experiences have shown that the level of livestock feed production determines, to a very large extent, the scale and speed of development of a livestock industry. Accompanying develop of China's "four modernization" construction and gradual improvement in the people's livelihood has been a demand for increased production of meat, eggs, milk, and such livestock products, and this has required that livestock feed work be placed in the position it deserves in the national economy. A look at the current situation in China shows that many places have not accorded livestock feed work sufficiently serious attention, and they have not given attention to the production of compound livestock feeds that have all nutrients in abundance to meet the needs of livestock and poultry growth and development. In national terms, the basic state of affairs in livestock industry production as a whole is as follows: long periods of growth, slow weight gain, slight egg production, low milk yields, poor quality of livestock products, high raising costs, and low livestock feed efficiency. In advanced livestock industry countries, the rate of removal from inventory for hogs is about 150 percent, but in China it has fluctuated around 60 percent for many years. In countries gaving a developed livestock industry, for each jin of weight gain in hogs, about 3.5 jin of full rate compound feed (containing 60 to 70 percent grain) is consumed, but in China half again as much grain is used, and the lean pork rate is low. As of the end of 1979, China had 319.7 million hogs in inventory and produced 20.03 billion jin of pork (10,015,000 tons) of pork, while the United States had 60.1 million head in inventory and produced 7 million tons. Average amount of pork output per head in inventory at year's end was 31 kilograms for China and 116 kilograms for the United States. Beijing's factorized chicken raising sets a high standard for China, but the amount of feed consumed to produce 1 jin of eggs is 12 percent higher than in countries with a developed livestock industry (2.6:1 for Beijing and 2.5:1 abroad).

1. Situation in Development and Use of Livestock Feed Resources:

(1) Feed grain use is irrational, feeding being done with whatever happens to be available. China uses about 10 percent of its total grain output as feed grain for development of the livestock industry. In 1980, feed grain amounted to 70.6 billion jin of which feed grain withheld by production teams amounted to 54.8 billion jin or 77.6 percent, and state award sales of feed grain for sales of hogs to the state amounted to 11.500 billion jin or 16.3 percent. Feed grain used in rural villages for the raising of hogs accounted for 94 percent of the total, and if 14 million jin of grain husks (or 30 percent of the national output) is added to this, total processed compound feed amounted to 100 billion jin. Converted at a fairly low feed to pork ratio (4:1), 25 billion jin of pork was derived, which was 2.5 billion jin more than the pork output for the year. Survey done in Qingfu County in Shanghai showed that after use of mixed feed was promoted, the level of feed consumption gradually declined during the past 3 years. A comparison of 1980 with 1978 showed that in this county the amount of feed used per fattened hog fell from 550 jin to 475 jin, a decline of 13.6 percent. Calculating on the basis of the 340,000 head of fattened hogs marketed in 1980, that amounted to a saving of 25.5 million jin of feed, a saving for the province of more than 3 million yuan in feed expenses. By raising the return on feed by 10 to 15 percent, the fattening period can be shortened by 2 to 3 months. Building of compound feed processing plants or mixed feed processing plants is an effective way of using limited feed grain resources to change the feeding of a single kind of feed and increase output of livestock products. Yet, in 1980 China's annual output of mixed feed (a considerable portion of which was simply mixed up) was only 820,000 tons, or about 2 percent of the country's total output of feed, somewhat more than 30,000 tons of which was fairly full rate compound feed.

(2) Use of paddy rice to raise hogs in most areas in the southern part of the country is very senseless. A comparison of nutritional value shows the crude protein content of paddy rice to be from 20 to 35 percent lower than for corn and wheat, and digestibility lower by between 10 and 20 percent. Departments concerned in Shanghai have made an analysis that showed that during 1965, 20 percent of the feed withheld in the city was corn and 11.4 percent was early rice; the remainder was wheat and naked barley. On average, every 100 jin of livestock feed contains 57 feed units (1 feed unit equals the nutritional value of 600 grams of digestible starch). By 1975, more than 75 percent of the feed was paddy rice, and the amount of wheat and naked barley had dropped to 25 percent. Virtually no corn was fed (only 0.7 percent). On average, each 100 jin of feed contained 46.2 feed units. For the same 100 jin of feed withheld, there was a difference of 11 feed units or a decrease by almost one-fifth in the nutritional value. Incomplete statistics show that in Hubei Province, more than 4 billion jin of paddy rice is used in livestock feed annually; in Guangdong Province it is almost 2 billion jin. Comparison of quantities used as feed shows that, on average, each mu of dryland paddy has 97 fewer feed units than corn (nutritional value calculated on the basis of average output for the 10 year period 1964-1973 by departments concerned in Shanghai).

(3) Use of cake residues for livestock feed has yet to be generally promoted. Of all cake residues, those showing most promise for use in livestock feed are cottonseed cake and rapeseed cake. In 1980, China produced 6 billion jin of cottonseed cake, and 3 billion jin of rapeseed cake. These two kinds of cake residues contain between 30 and 40 percent crude protein, and the digestible energy in them is close to 3,000 kilocalories per kilogram. They are a major source for protein livestock feeds. Inasmuch as it takes quite a while for these cake residues to be converted into manure, since their conflicting use in livestock feed has not been well resolved, since the masses do not yet fully understand techniques for their detoxification, and since there are as yet no genuinely effective methods whereby chemical fertilizer is offered in exchange for cake residues, most cottonseed cake and an overwhelming portion of rapeseed cake is used directly as fertilizer. Statistics from the former Ministry of Grain show that in 1980 cake residues resulting from processing of oil-bearing crops by grain departments nationwide amounted to more than 5 billion jin. This was in Beijing, Hebei, Shanxi, Liaoning, Heilongjiang, Jilin, Shanghai, Jiangsu, Shandong, Sichuan, and Henan, but only 400 million jin was retained for use as livestock feed. If it were possible within a short period of time to use half (4.5 billion jin) of the cottonseed cake and rapeseed cake produced in the country for livestock feed, and add it to daily feed at a 15 to 20 percent rate, about 22.5 to 30 billion jin of compound livestock feed could be made. Figuring 500 jin of compound feed per fattened hog, the protein feed problem could be solved for between 43 and 60 million head or between 30 and 40 percent of the fattened hogs removed from inventory throughout the country.

(4) Relatively poor attention given to the processing, movement, storage, and use of crop stalks and stems. In China only about 30 percent of the farm crops and the stalks and stems produced per mu of land are used for food (including those eaten by livestock or poultry and converted into meat, eggs, and milk.) More than half are used for fertilizer or fuel. More than 730 billion jin of major farm crop stalks and stems suitable for use as livestock fodder are produced in the country (of these, peanut vines contain about 10 percent crude protein, and the stalks of pulses contain 7 percent). British researchers believe that in long range terms, stalks and stems should be regarded as major livestock fodder. Denmark is now studying satisfactory methods for promoting the processing of stalks and stems. To proceed from China's realities, how to deal with cyclical transformation relationship among livestock feed, fuel, and fertilizer requires study, design, and production by the machine manufacturing sector of equipment suited to the processing, mixing, and storage of various kinds of stalks and stems, methane research departments, animal husbandry research units, and production departments jointly coordinating for a good job of rational use of crop stalks and stems.

(5) North China's pastoral areas contain 3.3 billion mu of useable grasslands on which there are now more than 94 million cattle, horses, and sheep. This converts to more than 188 million sheep units, or 1 sheep for every 17 mu of grassland. But administration and management, conservation and improvement, and rational use have not been done well, resulting in misuse of pasturelands and overgrazing; the grasslands have been seriously damaged and degenerated.

Today a normal year's harvest amounts to about 300 billion jin of dry green hay, a 70 percent utilization rate for which amounts to only 210 billion jin or an average 1,100 jin per sheep, which is only 3 jin of hay per day (the normal requirement is 5 jin), a 40 percent shortage. When disasters strike, large number of livestock are likely to die. Were it possible to strengthen the building of the grasslands in a planned way and increase the current hay output to 400 jin per mu for a hay output totaling somewhat more than 1.3 trillion jin, 1 sheep per 7 mu of grassland could be raised, and the number of livestock could be more than doubled. Were it possible to increase hay output to the levels attained in foreign countries, 1 sheep per 2 to 3 mu could be raised and the potential would be much greater. Problems in building and using grassy mountains and grassy slopes in farming areas are also very numerous, and a tremendous potential for development exists.

(6) Green manures are plants belonging to the pulse family whose protein content is fairly abundant. In dry Chinese milk vetch, for example, the crude protein content is a general 20 to 30 percent. Computations done by agricultural departments in Jiangsu Province show 10 million mu of winter green manure in the province for yields averaging 4,000 jin per mu or a total of 40 billion jin, the digestible energy from which is the equivalent of 5 billion jin of barley and the crude content the equivalent of 3.8 billion jin of bean cake. In 1980 the area of the country sown to green manure was 110 million mu for an extrapolated output totaling 440 billion jin, having a digestible energy equal to that of 55 billion jin of barley, and crude protein equal to that of 41.8 billion jin of bean cake. Were half the figures to be used, the digestible energy would be equivalent to 27 billion jin of barley, and the crude protein would be equivalent to that of 20 billion jin of bean cake. Furthermore, the potential for increased green manure crop yields is very great. With just a little improvement in field care, yields could be increased manifold. This is an important source of plant protein livestock feed. Right now most important is research to solve problems in storage methods (green manure crop green storage techniques are not up to standard). In long range terms, with gradual solution to energy problems and gradual improvements in techniques for using solar energy, corresponding breakthroughs on problems with rapid drying techniques and cost problems may be possible. This is a livestock feed resource peculiar to China, and prospects for its use are extremely hopeful.

(7) Purple flower alfalfa is often called by the beautiful name, "king of the pasture grasses." When dried, it has a crude protein content of between 18 and 28 percent. It has been grown in China for more than 2,000 years, and it has been closely related to the breeding of superior local breeds of domestic livestock. The common oxen of Qinchuan, for example, are closely linked to the feeding of alfalfa for a long time by the local peasants in Shaanxi Province. However, it has not been given the serious attention it deserves in recent years, with the result that varieties have become mongrelized and have degenerated, and the area sown has gradually diminished over the years. It is suggested that in major purple flower alfalfa growing areas (Shaanxi, Shanxi, Shandong, and Xinjiang) agriculture and animal husbandry research units should include among their topics for research the breeding, farming, and prevention and control of diseases and insect pests

of alfalfa. Machine mnaufacturing departments should research, design, and manufacture equipment suited to local areas for use in sowing, harvesting, and processing so as to solve problems in prompt harvesting and storage as well as in pulverized alfalfa hay and granular feeds.

(8) Tree leaves can provide livestock feed that is rich in vitamins and protein. Analysis of data has shown a protein content of more than 20 percent in purple plumed scholar tree leaves. The crude protein content of the leaves of peach, apple, apricot, and pear trees is more than 10 percent. Between 1976 and 1981, Beijing pulverized 22.91 million jin of locust tree leaves it collected. This was equivalent to having received 7 million jin of crude protein. The Jiangsu Provincial Poultry Research Institute mixed 5 percent pulverized leaves into the compound feed it fed laying hens for a saving in costs of 3 yuan per ton of feed. Results of a study of the province's livestock feed resources and their use carried out by Jilin Provincial Science Commission organizations showed that 10 billion jin of pulverized leaves could be made from the leaves of scrub woodlands nearby rural villages alone. If the leaves from coniferous trees and broadleaf trees cast aside in cut over forests were to be pulverized, 5 million jin could could be obtained from just 1 percent of the cut over forests.

(9) The blook, bones, entrials, feathers and hair of animals as well as silkworm chrysalises, and miscellaneous inedible fish etc. can be made into animal protein livestock feed. According to survey data from the Wuxi Amalgamated Meat Processing Plant, the waste products (blood, bones, feathers, and hair) from the 400,000 hogs and 1 million fowl slaughtered there annually amounts to about 3 million jin, which can produce 300,000 jin of blood powder, 67,000 jin of powdered hair and feathers, and 180,000 jin of bone meal. A survey done by departments concerned in Tianjin shows that except for the 2 million jin of the 4.5 million jin of fresh blood from hogs, cattle, and sheep produced in the city annually that is used for food and industrial purposes, the remainder flows away or is collected for use as fertilizer. If it were turned into 400,000 jin of powdered blood, that would be the equivalent of 320,000 jin of crude protein. China has more than 200 amalgamated meat plants with a butchering and processing capacity of more than 100,000 head per year. If each of these plants added a processing shop capable of producing 100 tons of animal feed yearly, the annual output would be more than 20,000 tons, enough to provide the protein feed needed to fatten 1.6 million hogs or feed 3.6 million laying hens.

(10) Use of industrial byproducts and leftover bits and pieces has yet to receive sufficiently serious attention in China. In the United States, the quantity of food industry-processed leftover bits and pieces amounted to 8.3 million tons in 1974. According to Japanese briefing materials, 12 to 14 percent crude protein can be obtained from the use of bagasse for livestock feed. Thailand also uses bagasse (or citrus fruit leftovers), which after being fermented with chicken dung is used as feed for beef cattle. China annually produces about 5 million tons of bagasse (the water content of which is 50 to 55 percent), so there is a sizeable source of supply. Leftover from the processing of fruits also contain a considerable amount of crude protein. Examples include pineapple skins (crude protein content of 8.2 percent),

leavings from making grape wine (content of 9.1 percent), and banana skins (10.6 percent protein content), all of which are close to the crude protein content of corn. Other things include medicinal residues (terramycin, tetracycline, and aueromycin residues) which have a crude protein content of from 25 to 35 percent, close to the protein content of cottonseed cake and rapeseed cake. For these resources that can be used for livestock feed, the joint cooperation of light industrial, food and pharmaceutical industrial departments concerned is required for the organization of their processing for use. As a result of development of fermentation techniques, conditions already exist within China for the use of molasses (a leaving in sugar refineries) to produce lysine. In addition, technology for synthesis have also been mastered by relevant departments in China. Use of petrochemical industry intermediate products (such as acrolein, methyl mercaptan, and sodium cyanide) for the production of methionine synthetically is also possible.

2. Suggestions on Development of China's Livestock Feed Industry:

Inasmuch as China's financial and material resources are limited, the building of a complete livestock feed raw materials industry and livestock feed additives industry the way developed countries have done together with a matching livestock feed processing industry is clearly not realistic, and difficult to do. In view of China's characteristics, the building of a livestock feed industry must make full use of the initiative of each department of central and local governments and of communes and production brigades to begin building first small then large, and going from low grade to high grade to form an organic livestock feed industrial complex gradually. The building process should link large, medium, and small scale, with the medium and small predominating, with encouragement being given to communes and brigades to contribute funds themselves to build small scale livestock feed processing plants. In China 95 percent of the livestock feed grain is used in rural villages, and grain requirements can be met locally through the adaptation of general methods to local situations. The husks and cake residues required can be supplied locally. The overwhelming majority of raw materials come from communes and production brigades, and full use can also be made of green feed resources as rural livestock raising conditions permit. Requirements of these types of plants for trace ingredients to be added (vitamins, amino acids, and growth promoters) would be very low; consequently with a stable supply of raw materials, little change in varieties, and a simple and readily managed compounding of livestock feed, production capacity could be developed very rapidly. There could even be use made of mobile livestock feed processing equipment to take in raw materials for processing and providing service to brigades, villages, and households. In short, many forms could be used, with the adoption of no single model so that within a relatively short period of time the mixed feeds and compound feeds so urgently needed by collective livestock farms, specialized households, and key households could be produced and supplied in order to increase the livestock. Many places can also make use of all sorts of byproducts and leftovers by building blood powder plants, bone meal plants, feather and hair pulverization plants, fish meal plants, fruit residue livestock feed plants, hay pulverization plants, etc. to make full use of local labor and agricultural feed resources and animal and plant feed resources.

The state should concentrate some material and financial resources to operate key livestock feed plants that local resources cannot operate, the production of additives most importantly, to do a good job in serving locales. These industrial plants would be the mainstays of China's livestock feed industry, and would produce principally the pre-mixed livestock feeds containing additives (such as methionine and lysine) scale livestock feed plants to manufacture full rate compound livestock feeds, thereby spurring development of the entire livestock feed industry.

Production of pre-mixed livestock feeds containing additives would simplify the technicological processes in livestock feed plants, cut capital counstruction investment and transportation expenses, and would be an effective way in which to hasten building the livestock feed industry, to improve product quality, and to accelerate the transition to production of full rate compound livestock feed. In order to meet the needs of egg, milk, and meat production, large and medium size cities should similarly build livestock feed processing plants. On the basis of the experience of the Beijing Municipal Animal Husbandry Bureau's Stud Poultry Company, the building of one stud rooster farm plus one (or two) farms with 200,000 laying hens, plus one livestock feed plant would return 1.4 million yuan annually on investment, and would provide 4 million jin of chicken eggs. We should act on livestock industry production plans for large and medium size cities as integrated livestock, industial, and commerical enterprises develop to build group after group of livestock additive pre-mixed feed plants and livestock feed processing plants over a period of time. In building the plants, we should make sure that there is no duplication of construction. Production needs for which other departments have not made arrangements but which local areas urgently need should be taken care of by farming and livestock industry departments, with joint operation or some other method used to solve problems in cooperation and coordination involving raw materials, funds, and techniques.

DEVELOPMENT OF NEW SWEET POTATO DETAILED

Beijing GUANGMING RIBAO in Chinese 22 Aug 82 p 2

[Article: "Shen Jialian [4141 1367 1670], Yuan Baozhong [5913 1405 1813], and Zhu Chongwen [3612 1504 2429] Cultivated a New Variety of Sweet Potato; 'Xu Shu 18' Has Become the Champion of Varieties Bred by Our Nation; It Has Been Popularized Over More Than 18 Million Mu Throughout the Nation and Has Received the State's First-Class Invention Award"]

[Text] Researchers Shen Jialian [4141 1367 1670], Yuan Baozhong [5913 1405 1813], and Zhu Chongwen [2612 1504 2429] of the Agricultural Sciences Institute in Xuzhou Prefecture [Jiangsu Province] have cultivated a new variety of sweet potato, the "xu shu 18." They have made a major contribution to the development of the production of sweet potatoes in our nation. Recently, they received the state's first-class award for inventions. "Xu shu 18" has been popularized outside the experimental nursery for less than 6 years. It has been rapidly popularized over more than 18 million mu in northern China and central China to become the champion of the varieties cultivated by our nation ourselves.

Shen Jialian, Yuan Baozhong, and Zhu Chongwen spent over 20 years developing this new variety. It was only 9 years ago that they selected one from the several thousand strains in the experimental nursery. They labeled it "73-2518," meaning that it was sown in 1973 and numbered 2,518 in order. The last two numbers refer to the Japanese variety "sheng li bai hao"--the goal to be surpassed by the several thousand strains in the nursery.

"Sheng li bai hao" was developed in Okinawa, Japan. Because of its high yield and its broad adaptability, it had occupied the leading position among our nation's sweet potato varieties for a long period. One day in 1957, a leading comrade of the Ministry of Agriculture told Shen Jialian: "The sweet potato variety is still Japanese; we must think of ways to develop our own good varieties! This is what Premier Zhou has said." Encouraged after hearing this, Shen Jialian answered decisively: "Good. I will not close my eyes when I die if I do not beat 'sheng li bai hao!'"

In 1962, he and Yuan Baozhong and Zhu Chongwen were transferred from the Chinese Agricultural Academy to the Agricultural Sciences Institute in Xuzhou Prefecture. The three cooperated closely. Up to the time of the Cultural Revolution they had developed over 10 superior varieties and served an important function in production.

The final push began in 1972. At the time, Shen Jialian and Yuan Baozhong had collected over 460 sources of domestic and foreign sweet potato varieties. They studied the characteristics of each variety closely, and then they selectively used the superior parents for sexual crossing. In the spring of that year, they arranged over 40 pairs and conducted experiments. By harvest season, "73-2518" was selected for its outstanding comprehensive achievements. The leaves on the stem grew early, it produced sweet potatoes early, the sweet potatoes enlarged quickly, the sweet potatoes grew in concentrated bunches, the growth during the latter period was strong, there were many sweet potatoes, and the comprehensive properties were far ahead of the other varieties. Shen Jialian and the others examined it strictly. The results were as follows: It surpassed the "sheng li bai hao" in almost all indices; the yield was 40 percent higher than that of "sheng li bai hao!" The hope of surpassing "sheng li bao hao" had finally been realized!

Miracles continued to come forth. In 1976, the Agricultural Sciences Institute in Tai'an Prefecture [Shandong] planted "73-2518" at test points. In that year, root rot disease was widespread in Shandong. This type of destructive disease causes the roots of the sweet potato to rot. "Sheng li bai hao" also wilted, but "73-2518" continued to grow prosperously and produced a lot of sweet potatoes. After many observations and much analysis, "73-2518" was selected as the best superior variety at present that is highly resistant to root rot disease. In the second year, the Agricultural Sciences Institute in Xuzhou Prefecture also arrived at the same experimental conclusion.

The high-yielding and highly resistant "73-2518" quickly became popular in northern China and central China. For convenience, its name was shortened, and in 1976 it was officially renamed "xu shu 18" instead of "73-2518." It signifies a new breakthrough in our nation's breeding of sweet potatoes.

As "xu shu 18" was born, the history of a variety cultivated by our nation ourselves occupying the leading position in sweet potato production began. The breeding work by Shen Jialian, Yuan Baozhong, and Zhu Chongwen again opened a new page. They told reporters that "xhu shu 18" still has some shortcomings, such as its weak resistance to black spot disease and its ordinary taste. They are determined to cultivate an even better variety than "xu shu 18."

RURAL COMMUNE'S WORK SYSTEM ACHIEVEMENTS NOTED

HK020606 Beijing CHINA DAILY in English 2 Oct 82 National Day Supplement p 5

[Article by Hu Wenshun, secretary of the Shuangqiao People's Commune Communist Party Committee]

[Text] Shuangqiao people's commune in the Chaoyang District is one of Beijing's rural communes. It has 12,846 households who make up 47,719 people, and 52,000 mu (3,466 hectares) of farm land. There are 14,000 laborers and 7,000 factory and sideline workers. It is composed of five rural management areas with 62 production brigades.

The commune's chief concern is agriculture but at the same time, it is trying to develop in many fields. It has set up offices or stations in charge of industry and sideline activities, animals and fishery, hydropower, science and technology. There is also a hospital and a school for workers.

Great changes have taken place since the third plenary session of the Communist Party's Central Committee in December 1978. The establishment of various kinds of responsibility system was what the people wanted.

In only 3 years, major economic gains have set historic records. Agricultural and industrial gross income in 1981 amounted to 72.94 million yuan, an increase of 78 percent over the 40.94 million yuan in 1978. Average annual distribution per capita was 370 yuan, increased by 90.7 percent (194 yuan in 1978).

For 3 years running, Shuangqiao's farming, tree planting, animal raising, fishery and sideline production have all expanded, while crop yield has stabilized above 35 million jin (17.5 million kilograms).

The year 1981 was the sixth that its per mu yield reached over 1,000 jin (7,500 kilograms of grain from one hectare). The per unit area yield of 33,000 mu (2,200 hectares) of grain field was 1,067 jin (533.5 kilograms). Vegetable output has been 52 million jin (26 million kilograms) every year. Milk cows increased by 50 percent from 12,000 3 years ago to 18,000 now. Milk production was increased by 35.6 percent and pigs increased by 41.6 percent. The fish catch has doubled. Chicken farms, force-fed duck farms and orchards were expanded.

About 100 industry and sideline enterprises have been developed, run either by the commune, or by brigades. Gross income from these enterprises grew from 30 million yuan in 1978 to 50.13 million yuan, in 1981, an increase of 67 percent.

The commune has helped enrich Beijing's market by selling more produce to the state. Its commodity grain increased by 71.6 percent. It also provides the market every year with 45 million jin (22.5 million kilograms) of vegetables, 11.2 million jin (5.6 million kilograms) of fresh milk, 17,000 pigs, 230,000 jin (115,000 kilograms) of fresh fish, 500,000 jin (250,000 kilograms) of eggs, 60,000 ducks and 3.6 million jin (1.8 million kilograms) of fruits.

The increases are attributed to the responsibility system. The Wuliqiao brigade is an example. It contracted 54 mu of land (less than 4 hectares) to 28 commune members for specialized production. The total output was 62 percent higher than the previous year and the members' income quadrupled. The average value of production per mu (1/15th of a hectare) rose to 1,144 yuan. The average annual distribution to each laborer was 1,370 yuan with the highest more than 1,800 yuan.

In the last 2 years the living standard of the commune members has been improved. According to a survey, some 1,900 households have built 6,000 new houses. Fifty percent of the households have bought TV sets. Thirty percent of the brigades have set up pensions for elderly members over the age of 60, ensuring the livelihood of the commune members when they lose their ability to work.

Shuangqiao people's commune is looking forward to an even brighter future in 1983.

AGRICULTURAL BANK OF CHINA HOLDS MEETING

OW030940 Beijing XINHUA in English 0758 GMT 3 Oct 82

[Text] Shijiazhuang, 3 Oct (XINHUA)--China's rural savings deposits are more than treble those of 3 years ago and the amount of agricultural loans issued up to the end of August was 65.2 percent more than in the same period of 1978.

The figures were released at a recent meeting held by the Agricultural Bank of China and its branches on experience in improving the economic results of agricultural loans. According to the meeting, held in Shijiazhuang, capital of Hebei Province, rural savings deposits totalled 48,900 million yuan at the end of August. More than 66,900 million yuan of agricultural loans had been extended to rural collectives and individual undertakings by the end of August. About 98.9 percent of the loans due have been repaid.

Delegates to the conference attributed the good situation to rapid agricultural development and correct economic policies in rural areas.

The Agricultural Bank and the credit cooperatives have changed the practice of issuing the agricultural loans primarily for developing grain production and adopted the policy of encouraging the diversification of the rural economy. They have extended bank loans both to collective units and individual households to promote farming, forestry, stockraising, fishery, rural industries and other sidelines and helped peasants make fuller use of local resources.

The loans have helped stimulate commodity production and promoted rural processing industries and commodity circulation, it was reported at the meeting.

Some branches of the Agricultural Bank of China helped production brigades and teams solve problems that have resulted in expanded production.

Loans were extended to production units to popularize fine varieties of seeds and apply fertilizer in a scientific way.

According to the conference, a loan contract system has been instituted that is combined with purchase contracts.

As the autumn harvest season approaches, the rural credit cooperatives and branches of the Agricultural Bank of China are preparing for brisk financial activity.

DEFINITION OF CHINESE TERM ASCERTAINED

Beijing RENMIN RIBAO in Chinese 21 Sep 82 p 4

[In Column "Answer To the Readers": "How Should 'Fan Liang Fan' Be Understood?"]

[Text] Comrade Hu Yaobang proposed in his report to the 12th CPC National Party Congress that we strive by every means--consistent with an uninterrupted rise in economic benefit--to cause China's annual gross value of industrial and agricultural output to "fan liang fan." Several readers have requested an explanation of the numerical value of "fan liang fan." This newspaper has, therefore, made inquiries of the departments concerned, and their answers are as follows:

[Question] Comrade Hu Yaobang stated in his report that, by the end of the century, we should strive to "fan liang fan" China's annual gross value of industrial and agricultural output compared with 1980. Could you please explain how the phrase "fan liang fan" is to be understood?

[Answer] To strive by every means--with the proviso of an uninterrupted rise in economic benefit--to "fan liang fan" China's annual gross value of industrial and agricultural output by the end of this century is the grand objective proposed by the Central Committee of the party, after a comprehensive analysis of China's economics conditions and development trends. In line with China's practice [usage], "fan yi fan" means to double the base figure ["jishu de liang bei"], and "fan liang fan" means to quadruple the base figure ["jishu de si bei"]; therefore, using the 1980 gross value of industrial and agricultural output of 710 billion yuan as the base figure, and treating "fan liang fan" as "4 x," we obtain a product of about 2,800 billion yuan.

[Question] In his report, Comrade Hu Yaobang speaks of the 1980 gross value of industrial and agricultural output as being 710 billion yuan, whereas in the 1980 communique issued by the State Statistical Bureau the figure is given as 661.9 billion yuan. How come the two figures do not agree?

[Answer] The figure for 1980 gross value of industrial and agricultural output published in the Statistical Communique--661.9 billion yuan--was computed on the basis of 1970 constant prices. The figure of 710 billion yuan cited in Comrade Hu Yaobang's report was computed on the basis of 1980 constant prices.

Because it speaks of an objective over the next 20 years, it is a little closer to reality to use 1980 constant prices than to use 1970 constant prices. In China's plans and statistics, [the use of] "constant prices" means the use of prices of products in one given year to compute the fixed price of the gross value of output, and thereby to observe the rate of increase in each [succeeding] period.

BRIEFS

COTTON BOLLWORM VIRUS--Wuhan, 4 Oct (XINHUA)--Chinese biologists have designed and made the country's first set of equipment for cotton bollworm virus culture, marking a new step forward in controlling the pest, according to the Shashi Applied Automation Technology Institute in Hubei Province. The virus obtained from 5 to 10 cotton bollworms can mix enough insecticides for 1/15th of a hectare of cotton. The killing rate is more than 85 percent, research personnel say. Funded by the State Science and Technology Commission, the experiment in streamlining the virus production will soon enter into its intermediate stage. The equipment was designed by the Shashi Applied Automation Technology Institute and the Jingzhou Prefectural Institute of Microbiology. It consists of a mating and ovipositional box, a feed distributor, a worm breeding plate, a virus infection machine and a worm breeding plate washing machine. The streamlined method is between 10 and 20 times more efficient than the test tube breeding method. The feed mix costs are low and the mix does not affect the worm's physiological habit, research personnel say. China obtained the first nuclear polyhedrosis virus from dead cotton bollworms in 1974. RAINY SEASON AFFORESTATION--Beijing, 28 Sep (XINHUA)--China has finished afforestation work for this year's rainy season. A total of some 6.8 million mu were afforested in Yunnan, Shandong, Henan, Beijing, Tianjin, Hebei, Shanxi, Nei Monggol, Shaanxi and Liaoning. Of this acreage, 1.03 million mu were afforested by using aircraft to dispense tree seeds. Aside from this, 115,000 mu of saplings were grown in Hebei, Shanxi, Beijing, Tianjin and Shandong during the rainy season. [OW141115 Beijing XINHUA Domestic Service in Chinese 0028 GMT 28 Sep 82]

EFFORTS BEING MADE TO INCREASE LEAN PORK PRODUCTION

Nanjing XINHUA RIBAO in Chinese 12 Aug 82 p 2

[Commentary: "Let There Be More Lean Pork"]

[Text] As the living standards of the people in the cities and villages improve, the masses are asking for more lean pork to eat. This has presented a new problem for the production of live hogs: more lean pork hogs must be raised.

The concerned departments in the province have already begun to pay attention to this request by the masses. The raising of more lean pork hogs is needed in society, and material conditions make it possible. This year, our province has realized bumper harvests in rape. The amount of protein feed for live hogs will increase greatly, and good conditions for raising more lean pork hogs will be provided. At the same time, we should also see to it that the economic gain from raising more lean pork hogs is high. Comrades of the provincial Animal Husbandry Bureau have calculated: Last year, the whole province procured 17 million head of pork hogs; calculating at 180 jin per head and a slaughtering percentage of 70 percent, the percentage of lean pork produced now is about 35 percent in general. Each hog produces only 44 jin of lean pork. If the percentage of lean pork can be increased by 10 percent (this can be done), then each head can produce 56 jin 7 liang of lean pork [figures as published].

In order to raise more lean pork hogs, we must study and readjust the relevant policies, and at present we must strengthen the selective breeding of lean pork hog varieties and select lean pork type hog varieties suitable to the feeding conditions in each locality in order to provide sources for popularizing the raising of lean pork hogs over a large area. Today, this paper reported on an experiment by Ningzhenyang Prefecture to improve cross-breeding of wild boars and lean pork type hog species. This is a welcome beginning. According to reports, many scientific and technical persons throughout the province have already begun to carry out this work. The managerial departments at each level must actively provide guidance, support this work in many ways, rapidly establish a number of bases for the breeding and cultivation of lean pork type hogs, and hasten the progress in breeding lean pork type live hogs.

Of course, the development of lean pork hogs also involves the problem of the type of feed. To raise lean pork hogs with a higher level of protein, we must have feed with a higher protein content. The potential of sources of protein feed in our province is large. Each year, the whole province produces 100 million jin of cottonseed cakes and vegetable cakes. If 70 percent could be used "first as feed and then as fertilizer," this could greatly raise the protein level in the feed needed for raising lean pork type hogs. Panwan Commune in Sheyang County did this well in comprehensively utilizing feed resources. This commune used 80 percent of the cottonseed cakes to feed the hogs. For 2 consecutive years, each family sold an average of three hogs, and food grains and cotton also increased in output. Therefore, we must advocate the use of cottonseed cakes and vegetable cakes to feed the hogs first and then as fertilizer in the fields in order to solve the problem of protein feed needed by lean pork hogs. The food grain departments should more actively develop and coordinate the feed processing industries so that the exchange of "the two cakes" can be done well. According to the stages of growth and development of live hogs, different types of mixed feed should be supplied. In general, as long as everyone exerts efforts and every sector coordinates with the others well, there will gradually be more lean pork hogs.

PROVINCE DEVELOPS FOOD PROCESSING INDUSTRY

OW050840 Beijing XINHUA in English 0801 GMT 5 Oct 82

[Text] Shenyang, 5 Oct (XINHUA)--Liaoning Province is actively developing its food processing industry by making use of locally grown produce, according to the provincial industrial department.

In the first 8 months of this year, the output of canned food, beer, gourmet seasoning and dairy products increased by 15 percent to 31 percent compared with the same period of last year.

The province now has 16 breweries which produced 139,000 tons of beer last year as against the 57,000 tons in 1978, and the average amount consumed by each person increased from 1.87 kilograms to 4.1 kilograms during this period. The Shenyang beer factory is planned to be expanded into one with an annual capacity of 100,000 tons to satisfy the 2.6 million population of the city.

The nine small sugar plants in the province are now producing 50 varieties of products. Five of them are being expanded and transformed to increase the capacity from the present 200 tons to over 500 tons of sugar each.

All this is part of the efforts made by Liaoning Province, China's leading heavy industrial center, to speed up the growth of its light industry in line with the national policy to provide more consumer goods for the people.

In order to better meet the needs of the domestic and foreign market, the province has consistently improved the quality of its products, the officials say. Some of the products, including Shenyang liquor, Snowflake brand beer, Dalian rice wine, Hawthorn wine, applie wine, Dongfeng brand cigarette and Dalian canned conch, are very popular.

The province now grows hops, grapes, tobacco, sugarbeets and fruits and vegetables on a total of 28,000 hectares. It has also set up an asparagus production base with a total acreage of 1,530 hectares, which is expected to help increase the output value of canned food industry by 30 million yuan a year.

The total output value of the food processing industry of the province last year was 1,130 million yuan, 44 percent above that of 1978.

Light industrial output value in the province has increased from 26.7 percent of the total industrial output value in 1978 to 37.6 percent last year, making the proportions between heavy industry and light industry more rational, according to the industrial department.

PACE OF ANTIFLOOD PROJECTS BEING ACCELERATED

Xian SHAANXI RIBAO in Chinese 30 Jul 82 p 1

[Article: "Xianyang Weihe Flood Prevention Project Hastens Progress; as of 12 July, Engineering Projects on the Two Dangerous Segments at Xianyang Gudu and East of Gongluqiao Have Been Completed"]

[Text] Before the arrival of the flood season, the Xianyang City People's Government concentrated manpower and materials and grasped the construction of the flood prevention project on the Weihe. As of 12 July, the engineering projects on the two dangerous segments at Xianyang Gudu and east of Gongluqiao have been completed. Over 500 meters of new embankments have been built, and over 30,000 cubic meters of earth construction have been completed. Of the 1,550 concrete poured stakes needed for the entire project, 910 have been poured, and the first phase of construction has basically ended.

The Weihe flows from west to east around Xianyang City. In recent years, because the silt in the riverbed has increased, the river channel has become narrow and the water level has continued to rise. This year, to safeguard the people's lives and to prevent the loss of state property, the Xianyang City People's Government actively organized personnel in May to begin work to heighten and fortify the 2,000-meter-long embankment and to pour new foundations for the 2,300 meters of river without embankment.

During the past 2 months of construction on the Xianyang Weihe flood prevention project, many units have actively sent people to participate in construction and have quickened the progress of construction. To enable Xianyang City to safely survive the flooding period, the city people's government recently held a mobilization meeting for the second phase of construction. It decided to complete the earth embankment project along the section of the river with newly poured foundations before the flooding period arrives and to complete key well-sinking projects.

BRIEFS

LESHAN PREFECTURE RICE PRODUCTION--The per mu yield of the 3.45 million mu of mid-season rice in Leshan Prefecture in Sichuan Province was some 800 jin and total output increased by approximately 200 million jin and was 7.5 percent more than last year. The prefecture has trained some 1.7 million rural cadres and peasant technicians, cultivated high-yielding demonstration plots of some 900,000 mu and set up some 80,000 scientific and technological demonstration rooms. [Chengdu Sichuan Provincial Service in Mandarin 0030 GMT 4 Oct 82]

WENJIANG PREFECTURE PADDY OUTPUT--According to preliminary statistics, total output of paddy rice in Wenjiang Prefecture, Sichuan Province, this year was some 3.3 billion jin, some 200 million jin more than last year. The per mu yield was some 810 jin. The prefecture has a large number of communes whose per mu yield exceeded 1,000 jin. Peng County has 680,000 mu of paddy fields, whose total output exceeded 700 million jin. Qionglai County has 15 communes, whose average per mu yield of paddy rice exceeded 1,000 jin. [Chengdu Sichuan Provincial Service in Mandarin 0030 GMT 5 Oct 82]

RELIEF WORK CONFERENCE--The Sichuan Provincial People's Government recently held a conference on relief work in Fuling, Daxian, Wanxian and Leshan prefectures. The conference looked into and arranged for relief work through production this winter and next spring. Vice Governor Liu Haiquan presided over the conference and spoke. Responsible comrades of relevant departments at the provincial level attended. The conference demanded that leaders at all levels and the masses in the stricken areas make sustained and redoubled efforts and further do relief work well. In particular, cold winter is soon approaching, and it is necessary to step up solving the masses' livelihood problem during the winter. In relief work, it is essential to adhere to the principle of self-reliance and mutual assistance. All places must strengthen the management and use of relief materials and funds, which should be used only for the purpose of relief and should not be misappropriated. [HK071346 Chengdu Sichuan Provincial Service in Mandarin 0030 GMT 5 Oct 82]

RICE HARVEST--Chengdu, 7 Oct (XINHUA)--Sichuan Province, China's leading rice producer, reaped a record 16.6 million tons from its 2.9 million hectares of semilate rice, one million tons or 6.4 percent more than 1981, itself a good harvest year, according to provincial authorities. Per-hectare yield was more than six tons in Mianyang, Wenjiang, Leshan, Neijiang, Ya'an, Young-chuan, Chengdu and Dukou prefectures and cities, a record for these major semilate rice growers. The authorities attributed the increased yields to popularization of improved rice strains, new cultivation techniques and the services of local agrotechnical stations. Improved rice strains were used throughout the province except in outlying mountainous areas. Nearly one million hectares were planted to corssbreed, 130,000 hectares more than last year. New cultivation techniques applied included two-stage hot-house seedling nursing and the breeding of strong seedlings at the tillering stage. In Yongchuan, Nanchong and Yibin prefectures, peasants applied zinc fertilizer to prevent seedlings from turning yellow. This year, the province also instituted a system by which commune agrotechnical stations contracted with rice growers to provide technical services for rice production. I. GENERAL INFORMATION

COMPUTERS USED IN CROP DISEASE FORECASTING IN ZHEJIANG

Beijing JISUANJI SHIJIE [CHINA COMPUTERWORLD] in Chinese No 18, 20 Sep 81 p 1

[Article: "Zhejiang Province Achieves Preliminary Results in Using Computers for Long-Term Forecasting of Crop Diseases"]

[Text] In the past 1-2 years, the Zhejiang Computer Technology Institute has been working in coordination with Zhejiang Province Academy of Agricultural Science and Zhejiang Agricultural Department's Central Station for Tracking and Reporting Diseases and Pests in a joint project using the computer to conduct (long, medium and short term) forecasts on late rice crop disease in the province, and wheat/barley scab. Some encouraging results have been achieved. The success of long term forecasting, in particular, is of great use to agricultural production, as medium and short term forecasting can only be conducted during the middle or late growth period when the crop diseases are already beyond control and pesticides are no longer effective.

Last year, the mathematical statistical method was used in forecasting Zhenhai County's late rice crop diseases and insect pests. The computation results predicted serious calamity and the information was circulated in advance among concerned groups. It turned out that the prediction tallied with the actual disease conditions. At the end of February this year, they conducted the same computation on Jiaxing Prefecture's major and minor diseases; the results predicted light disease occurrence, which also tallied with actual conditions. Based on the long, medium and short term forecasting computation system, the Agricultural Science Institute of Jiaxing Prefecture worked in coordination with concerned crop protection departments and changed the old practice of extensively spraying "safety pesticides" by limiting the spraying area to only 220,000 mu of the entire region's 1 million odd mu, thus reducing the spray areas by 780,000 mu and cutting down the pesticide cost by over 470,000 yuan. The computer has earned the reputation of being a "good consultant" for predicting crop diseases and insect pests.

In recent years, the Institute and the Crop Protection Institute under Zhejiang Academy of Agricultural Science have expanded their late rice blast forecasting operations to 5 major prefectures and 18 counties. The computer has processed 170 years of accumulated historical information and 1.2 million data. Five comprehensive forecasting stations have been set up. The

Provincial Agriculture Department uses the computer's computation results as basis for its reports; in collaboration with the province's central station for tracking and reporting crop diseases and insect pests, it is planning to expand the wheat/barley scab disease forecasting operations to 32 counties throughout the entire province, thus allowing the computer to play a greater role in forecasting crop diseases and insect pests, open up a new path for our country's battle against crop diseases and insect pests, thereby insuring bumper harvests all year round.

BRIEFS

UNPRECEDENTED SAVINGS--Since the Third Plenary Session of the 11th Party Central Committee, China's rural savings institutions have seen unprecedented development, three consecutive steps forward having taken place during the last 3 years as follows: A 38.6 percent increase over 1978 in 1979; a 49.8 percent incremental increase in 1980; and another incremental increase of 42.1 percent in 1981. The amount of increase during these 3 years has been almost double the development of savings deposits during the previous 29 years. As of the end of 1981, average savings per capita of rural population were 25.66 yuan, a 16.79 yuan increase from the end of 1978. This year new increases have occured in rural savings. As of the end of July the sum stood at 24,898,000,000 yuan, an incremental increase of 17.4 percent over last year, with average savings per capita of rural population amounting to 30.12 yuan. GANSU

WIDESPREAD ARMYWORM DAMAGE TO CROPS PREDICTED

Lanzhou GANSU RIBAO in Chinese 1 Jul 82 p 2

[Article in "Agricultural Forecast" column by Gansu Provincial Plant Protection Center: "There Are Many Armyworms in Our Province This Year and They Must Be Controlled Without Delay"]

[Text] Since the last 10 days of May this year, a great numer of adult armyworms have swarmed into our province. The development of the adult armyworm is relatively concentrated, and its peak period came about 10 days earlier than in previous years. The number of adults is close to that in the year of the highest incidence over the past 10 years. One black light lamp and two imago-killing devices of the measuring and reporting station of the Agricultural Bureau in Qingyang Prefecture killed 2,041 adult armyworms in the first 10 days of June, 204 times higher than the number killed in the same period of last year, and the greatest development of adults occurred on 1 and 7 June. In Lintao County, the peak development of adults occurred on 2 June, 12 days earlier than it did last year. In the first 10 days of June, a black light lamp of the measuring and reporting center of the Agrotechnical Center in Gaolin County killed 1,446 adults, 20 times the number in the same period of 1980 and 14 times the number in the same period of 1981. The peak period for adult development was from 2 to 4 June.

It is estimated that this year armyworms will be of medium incidence in the central and eastern parts of Gansu, but in some areas they will be of high incidence. In the counties of Wenxian, Chengxian, Huixian, and Tianshui, there will be a medium incidence. After 5 July, most of the armyworm larvae will have completed their three-stage development and will enter the intense feeding period of their post three-stage development. In the first and second 10-day periods of July, they will run rampant and harm such crops as wheat and corn. Therefore, in the eastern, western, and southern areas of Gansu, the crucial period for controlling larvae in the pre-third stage is from the end of June to before 5 July, and for the middle part of the province this cruicial period is the first 10 days of July.

The most effective method of control at present is the use of agricultural chemicals: 1) every mu can be sprayed with 2 jin of powder containing 6 percent dipterax; for every mu, 2 liang of raw DDVP, to which 5 jin of water is added, can be mixed with 40 jin of fine sand (earth) to form DDVP arsen opyrite for spraying evenly in the fields; on every mu, 150 jin of crystal dipterax 800 liquid can be sprayed; 4) on every mu, 150 jin of 600 liquid containg 50 percent sevin can also be sprayed; and 5) on every mu, 1 liang of raw (sulfuric phospherous) to which 150 jin of water is added, can be sprayed. When spraying with the motorized sprayer, the diluted consistency of the agricultural chemicals can be about 5 times greater than that when using ordinary sprayers. It is hoped that the agroscience plant departments at all levels will strengthen their forecasts and quickly control the armyworms.

VARIOUS PARTS OF PROVINCE GIRD EARLY FOR FLOODS

Lanzhou GANSU RIBAO in Chinese 13 Jun 82 p 1

[Article: "Making Good Preparations Without Delay for Flood Protection Ensures Safety During Flood Season"]

[Text] According to a news roundup by our correspondents, many localities in our province, conscientiously summing up the experiences and lessons of the past, have made preparations without delay this year for flood prevention in order to ensure safety during the flood season.

In line with this year's changeable weather and early indications of floods, Jiuquan Prefecture has set up defenses for "protection against catastrophic floods" and had given priority to protecting cities and towns from floods. It had determined that the key to flood control is its 6 reservoirs, 4 dikes, and 5 channel heads. Beginning in the first 10 days of May, it held meetings on, made arrangements for, and carried out various flood-control measures. Nine flood-prevention headquarters have been set up in the prefecture with 109 working personnel assigned to them. At the 6 large and medium-sized reservoirs, 36 emergency teams and 7 emergency squads have been organized, totaling over 3,700 persons. Over 23,000 straw bags and gunnysacks have been prepared. Conscientiously drawing a lesson from the collapse of the secondary dam at Danghe Reservoir in 1979, Danhuang County has taken flood protection measures without delay. In the county, the key defenses are the Danghe Reservoir, Zhonggan Head, Zonggan Channel, Huangshui Dam Reservoir, and Chengxi Flood-Control Dike. At these places these emergency squads totaling 640 persons have been set up. The 11 people's communes in the county have each formed an 100-man emergency squad made up of cadres, people, and soldiers at the basic level.

Liangdang County, which last year suffered a catastrophic flood, first of all this year dispelled the idea, which lowers one's guard and underestimates the threat, on the part of some people that "we had our flood last year so there won't be any problem this year," and carried out flood protection ideologically and organizationally. Based on the lessons of last year, where the riverbed and ravines silted up, the river rose suddenly and sharply, and dikes were breached and dams destroyed, the county decided to take the following flood-protection measures: clearing way silt in river branches and canals, clearing away obstacles in the Yao Channel and the Guan Channel, and plugging leaks. By the end of May, over 3,100 meters of the 3,720 meter-long flood-prevention project on the Liangdang River had been completed, and it is estimated that the project will be basically completed by the first 10 days of June. Not only was the base cleaned 1.2 meters deeper than in the past but the dikes and dams were made half a meter higher and at their key positions were given reinforced concrete structures. The project to clear away obstacles in the Guan Channel is basically finished.

Jingyang County, which is located along the bank of the Huanghe River at an early date this year overcame the idea of leaving things to chance and firmly carried out the policy of "putting protection first." The county vigorously grasped the work of repairing, strengthening, and setting up defenses on water-damaged projects and important dangerous sections. The important stretches of river dikes that touch villages and irrigation facilities were made the keys to flood protection, and as fast as possible repairs were carried out to strengthen river dikes so that prepardeness would avert peril. Jingchuan County, located at the confluence of the Jinghe and Ruihe rivers, is now, with the urban construction bureau and other departments concerned in the lead, organizing technicicans to carry out flood-prevention measures such as a big safety inspection of the four ditches and the street flood drains and culverts in the city proper and its environs in order to eliminate hidden dangers in good time. This spring the county also repaired and strengthened the dike protection and bank revetment water-damaged projects along the Jinghe and Ruihe rivers, thereby strengthening their flood-control capacity.

FULFILLMENT OF SUMMER GRAIN QUOTAS AHEAD OF SCHEDULE REPORTED

Guangzhou GUANGZHOU RIBAO in Chinese 6 Sep 82 p 1]

[Article: "Guangzhou Fulfills Summer Grain State Purchase Quotas Ahead of Schedule; Broad Masses of Commune Members Celebrate Victorous Convening of 12th Party Central Committee With Real Action"]

[Text] The broad masses of commune members in Guangzhou's suburban counties (and districts) have celebrated with real action the victorious convening of the 12th Party Central Committee by eagerly selling patriotic grain to the state. The city fulfilled its summer grain state purchase quotas 10 days ahead of schedule. As of 31 August, 574 million jin of paddy had been put into storage in 101 percent completion of state purchase quotas. The amount stored represented an increase of 89 million jin over the same period last year. In celebration of the victorious fulfillment of state summer grain purchase quotas, the Municipal Grain Bureau held an awards meeting on 3 and 4 September.

The speed of storage of this year's state purchased summer grain, the large quantity, the good quality, and the high enthusiasm of the masses for selling their grain to the state were unprecedented. During the high point of storage, people made 60,000 trips daily to haul grain. Households in the municipality selling 10,000 jin of grain numbered 185. In Hua County alone, households that fulfilled their quotas for the entire year from a single crop numbered more than 22,000. This was more than 37 percent of the total number of households. Grain sent to storage was dry, plump, clean, and fresh in color and luster.

This year's fine situation in state purchase of summer grain fully reflects the power of party policies. Since the Third Plenary Session, the party's various rural programs and policies have been comprehensively implemented; various forms of production responsibility systems have been perfected and improved; the obligations commune members owe to the country and the collective have been spelled out; the enthusiasm for production of the broad masses of peasants has been fully aroused; and these actions plus scientific farming and selection of superior varieties of hybrid rice for growing have brought about a bumper harvest from the early rice crop, with an increased harvest in every county and prefecture. In addition, the 3 year guarantee policy in assumption of sole responsibility for grain production by the masses; went from understanding to confidence, and from confidence to a sense of relief, thereby stirring enthusiasm for early sales of grain, sales of good grain, and much sales of grain.

The fulfillment of state summer grain procurement quotas is also inseparable from the efforts of the broad masses of employees in grain departments. After rural villages instituted various forms of production responsibility systems, peasants changed from a system whereby production teams sold the grain to household sales of grain, and the number of grain selling units changed from the former somewhat more than 17,500 to somewhat more than 480,000. The amount of work at grain stations increased 22 fold. Faced with this new situation, grain departments spared no effort, and more than 5,000 employees worked round the clock, each working more than 10 hours daily. In order to hurry the pace of grain procurement, all grain stations increased the number of procurement sites, set up more scales, improved methods of receiving grain, and simplified grain receipt procedures.

In order to summarize experiences promptly and reward the advanced, the Municipal Grain Bureau decorated 30 advanced collectives and 217 advanced individuals at awards meetings.

ON-THE-SPOT MEETING URGES EFFORTS TO RAISE SOIL FERTILITY

Harbin HEILONGJIANG RIBAO in Chinese 27 Jun 82 p 1

[Article: "Do a Good Job of Raising Livestock and Collecting Manure So As To Effectively Restore Soil Fertility"]

[Text] According to a survey, the organic matter content of the soil in our province's cultivated land is now decreasing at an annual rate of from 0.1 to 0.2 percent. Recently, at an on-the-spot meeting on raising livestock and collecting manure, the provincial government exhorted rural areas throughout the province to build up the stocks of agricultural fertilizer centered on raising livestock and collecting manure, so that next year the application of farmyard manure will rise from its present level of 2,000 jin per mu to over 2,500 jin per mu.

There are many advanced models in livestock raising and manure collection in our province. In Bayan County, which for many years has had sustained stable and high grain output, most of the communes and production teams have got a tight grip on livestock raising and manure collection, and now the average per mu application of farmyard manure has reached 4,000 jin. By widely building up the "two management and five changes" and the "five haves and three diligents," Hailun County has attained bumper harvests in grain and livestok. Chaoyang Commune in Zhaozhou County, Fendou Commune in Lanxi County, Fuqiang Commune in Baiquan County, Liagang Commune in Suihua county, as well as Lianmin Production Brigade of Lianmin Commune in Keshan County organized their agricultural ranks to raise livestock and collect manure. They have raised pigs in sties and obtained high-priced manure and have also created various methods of making fertilizer, so that in the past several years the more their land is planted the more fertile it becomes, thereby beginning a good approach to organic agriculture. After seeing some models, the comrades taking part in the meeting held unanimously that to do a good job in raising livestock and collecting manure, combining agriculture with animal husbandry and enhancing agriculture's internal energy cycle are effective ways of changing the present local decrease in soil fertility and attaining stable and high grain output. They expressed their determination to spread widely these experiences. The provincial departments concerned have decided to reward a batch of units and individuals who achieve outstanding results in raising livestock and collecting manure.

Wang Luming, secretary of the provincial party committee and vice governor, presided over this on-the-spot meeting held in Bayan and other counties. At the meeting, various advanced units in raising livestock and collecting manure introduced their experiences.

EXHORTATION ISSUED ON FALL WHEAT PLANTING

Xian SHAANXI RIBAO in Chinese 29 Aug 82 p 1

[Article: "Province's Fall Sown Area Substantially Completed; Scientific Farming of Wheat Has Become a Priority Matter; Provincial Bureau of Agriculture Convenes Symposium on Experiences in Bumper Wheat Ouptut"]

[Text] Provincial Bureau of Agriculture statistics as of 24 August report a 281.2 million mu area in the province sown to summer grain. This approaches the area suggested for the province this year.

This year's bumper summer grain harvest greatly encouraged the broad masses of peasants to do a good job preparing for fall sowing to achieve continued increases in output next summer. In making arrangements for the area to be sown in the fall, all jurisdictions emphasized stabilization of the area, readjustments taking place within the context of stabilization, appropriate increases in crops that nurture the soil such as summer grain other than wheat and rice, and rapeseed, a main attack on improved yields per unit of area, and concentration of efforts on medium yield areas. A trend toward possible planting in excess of norms has been predicted for the province.

Not long ago, the Provincial Bureau of Agriculture convened a provincial symposium on bumper wheat harvest experiences at Fufeng. Delegates to the symposium included representatives and experts from each prefecture and municipal bureau of agriculture and agricultural institutes, and from 10 wheat growing counties and agricultural research units in Central Shaanxi. Emphasis was devoted to an exploration of the reasons for this year's bumper wheat harvest and to the laws governing increased yields. In addition, constructive ideas were put forward about this fall's sowing.

Comrades atending the conference believed the main reason for this summer's large bumper crop was active promotion of agricultural production responsibility systems. In communes and brigades that instituted "double contract" responsibility systems, results in increased yields were particularly outstanding. In places having identical natural conditions, results were vastly different when contracting was done and when it was not. When contracting was done, yields increased greatly. Second was steady rise in the level of scientific farming. Of course, this year natural conditions were good. The farmland water conservancy of many years, the readjustment of crop patterns, the promotion of superior varieties, and promotion of agricultural techniques all functioned to provide impetus. In future under a very good situation in which responsibility systems have been instituted, scientific farming should be made a priority matter.

In summarizing the technical measures accounting for this year's bumper wheat harvest, everybody acknowledged that four relationships were handled well.

The first such relationship was the relationship between wheat and fall grains other than wheat and rice, with wheat production being placed in an important position. This year's experiences further verify that whether grown on wetlands or drylands, wheat is a high yield crop whose potential is very great. To squeeze out summer grain with autumn grain, and to squeeze out wheat with grains other than wheat or rice blindly is incorrect. Of course, in different areas, how the relationship between wheat and grains other than wheat or rice will be worked out will have to be different. The fairly unanimous view of everyone was as follows: In the dry plains prefectures north of the Wei, it is necessary to continue to adhere to a program of "three dominants" (namely the dominance of summer grain in grain production, the dominance of wheat in summer grain production, and the dominance of wheat as the main crop). Central Shaanxi prefectures should treat summer and autumn crops with equal importance and strive for high yields from both seasons. In northern and southern prefectures of Shaanxi, the proportion of wheat is fairly small; however, in some places a potential for increased yields still exists.

The second relationship was the relationship between wheat colonies and individual plants, which promoted balanced yield increases. The number of spikes per mu, the number of grains per spike, and the per thousand weight of grains are the three fundamental elements that make up wheat yields per unit of area. To realize increases in wheat yields, it is necessary to adapt general methods to local situations of soil, water and fertilizer, climate, and varieties, to use scientific farming techniques, and to coordinate the relationship between growth and development of wheat colonies and individual plants. Last winter wheat seedlings were weak and tillering slight. Nevertheless, as a result of intensified care and spring rains, spikes were large and grains plump, and so a bumper crop was harvested. This circumstance demonstrates that the situation of individual plants plays a decisive role in output. Therefore, high yield areas should take the new path for increased yields of small plant colonies and sturdy individual plants. Owing to the restriction of soil fertility and water and fertilizer conditions, medium and low yield areas should continue equal emphasis to plant colonies and individual plants, make efforts to increase soil fertility and to increase the amount of slwing so as to make sure that main stems form spikes, and finally to guarantee that each mu has a sufficient number of spikes to achieve the goal of increased yields.

The third relationship was the relationship between planting and field care with planting being placed in the priority position. "Planting is most important but the wheat harvest depends on care" is a capsulization of long practical experience by the peasant masses. Wheat is a closely planted crop, and in dry plains areas in par-icular, because of the effects of precipitation, there is little room for maneuver for doing more work or increasing fertilization as part of field care once sowing has been done. In irrigated areas where water and fertilizer conditions are good, the room for maneuver to win victory through field care is greater, but good planting can greatly reduce increased expenditures resulting from additional field care measures. Twice as much can be achieved with half the effort. Good planting is the foundation and completely accords with the laws of wheat's growth and development. To a very large extent this year's bumper wheat harvest resulted from having devoted attention to three points when the wheat was sown last fall. First was scientific fertilization with increased applications of base fertilizer, promotion of deep fertilization with a combination of chemical phosphate and potash fertilizers, and fertilizing before the advent of winter. Second was a sensible layout of varieties with the area of the province planted to superior varieties amounting to 80 percent of all wheatfields. Third was triumph over disasters caused by rainfall and waterlogging in order to compress the sowing season so that 70 percent of the wheatfields were planted during the season that produces high yields. Without this foundation, achievement of a bumper harvest this year would have been hard to imagine. Likewise, even with such a foundation, had it not been for a series of field care tasks last winter and this spring, achievement of high yields would also have been impossible.

The fourth relationship is the relationship between winter and spring care with emphasis on care once planting has been done. In view of the situation last year of few basic wheat seedlings, little tillering, and small plant colonies before the arrival of winter, the former method in which control was dominant was changed for a combination of stimulation and control in caring for large plant colonies of flourishing seedlings, attention being concentrated mostly on stimulation and the breeding of sturdy seedlings for very good results. This experience merits serious attention. This year's experience with a bumper wheat harvest shows that that both pre-winter care and springtime care are both very important. Pre-winter care, in particular, positively cannot be overlooked. Emphasis should be placed on care as soon as planting has been done with "early" being the key word, making full use of the beneficial opportunity before the arrival of winter to intensify field care.

In short, as a result of natural conditions, experiences with increased yields in agricultural production are always formed by and accumulated by certain conditions. When we summarize experiences, it is necessary, first of all, to affirm many years of effective basic experiences and the new experiences produced by special conditions, and then dialectically and conditionally to apply them. One cannot take the experiences of any particular year as experiences of general applicability or use experiences under special conditions as basic experiences. For example, one cannot take "delayed planting of wheat can bring bumper harvests," or "delayed care can also increase yields" as basic experiences for promotion.

The time for fall sowing this year will soon be here, and comrades believe that beginning right now summer grain producing areas should concentrate attention on five matters as follows:

1. They should widely arouse the masses to make a mass summarization of this year's experiences in a bumper summer harvest to buttress their confidence in achieving an even greater bumper harvest.

2. They should respect the views of the masses and put production responsibility systems in place with all possible speed before fall sowing begins.

3. They should do an all-around good job of work preparatory to fall sowing, concentrating on preparations for applying base fertilizer to wheatfields, and to readying the land to maintain soil moisture and for the planting of wheat. They must be sure to plant the wheat on a genuine foundation for bumper harvests.

4. They should institute fall sowing quotas.

5. They should adopt various means for launching technical training. Agricultural institutes, technical promotion departments, seed departments, plant protection departments, soil fertility departments, and technical cadres should develop the signing of technical contracts with communes and brigades in a planned way, establish technical service stations and consulting offices, print and disseminate small scientific and technical bulletins, run scientific and technical discussion groups, engage in short term training, and widely publicize practical techniques in scientific farming.

On 21 August, the provincial government sent forward the report on the symposium proceedings and called upon all jurisdictions to concentrate their strength on doing a good job of preparing for fall sowing to lay a good foundation for a bumper summer harvest next year.

SPRING SOWING COMPLETED IN GOOD TIME DESPITE DROUGHT

Jinan DAZHONG RIBAO in Chinese 9 Jun 82 p 1

[Article: "Rural Areas of Our Province Complete Spring Sowing Task in Good Time"]

[Text] Led by the party committees and governments at all levels, the great number of cadres and masses in our province, fighting bravely against a serious drought, have completed the in spring sowing task in good time, and the quality of sowing on the over 46 million mu of spring fields is better than expected.

This year our province's spring sowing was carried out under conditions of a severe drought over consecutive years. The severity of the drought, the shortage of water sources, and the degree of difficulty in spring sowing were all rare in history. Faced with the serious drought, the great number of cadres and masses carried on the spirit of arduous fighting and consecutive battles and carried out a tenacious struggle. In March, the provincial party committee and the provincial government held, one after the other, a drought-resistance "double contract" [fixing output quotas based on households and peasant households assuming full responsibility for task completion] symposium and a cotton production symposium, and also sent out three work teams to go separately to various places to help resist the drought. Most of the responsible comrades of the provincial party committee and the provincial government went to the frontline of production and provided specific help at the basic level in solving real problems. The various areas, integrating this help with their own reality, conscientiously strengthened their leadership and universally focused on leadership, labor, time, water sources, and water implements. Because the leaders in these areas vigorously grasped affairs, the production responsibility system was further perfected, thereby promoting the successful carrying out of drought-resistant early spring sowing. Sowing was begun almost a week ahead of the time it began last year, and the entire sowing period was shortened by 10 days to half a month as compared to that of last year. "March seedlings" were brought to 70 or 80 percent of the cotton fields. In the process of preparing for sowing and sowing, the various areas by all ways and means expanded the area under irrigation bringing moisture to the soil, prepared the soil meticulously, increased the application of fertilizer, and regulated and replaced good strains, thereby laying a good foundation for agricultural bumper harverts throughout the year.

In order to do a good job of fighting the drought and carrying out spring sowing, the central authorities and the provincial authorities, under comparatively difficult financial circumstances came up with over 53 million yuan in funds for use by various areas in our province in water conservancy projects that would fight the drought, and at the prefectural and county levels over 46 million yuan were extracted from local finances to aid in the fight against the drought. Commerçial departments and supply and marketing departments gave priority to supplying materials such as drought-resistance oils; at a crucial moment in the sowing the electrical power departments provided an additional 150,000 kilowatts of electricity for fighting the drought and the industrial departments relinquished 170,000 kilowatts of electricity. The PLA stationed in our province gave energetic support in manpower and materiel.

Now, of the province's 46 million mu of spring-sown crops, over 80 percent have reached a full stand, and most of them are coming along better than last year. There is widespread squaring on the over 20 million mu of cotton, and some of the cotton has already entered the squaring stage. While getting a tight grip on summer harvest and summer planting, all the areas are vigorously taking measures, rationally deploying labor power, and intensifying spring seedling field management so as to stirve by every means to have the autumn season supplement the summer season and thus attain bumper harvests throughout the year.

TITLE: "Ways of Producing the Lean-meat Type Guangdong Pigs"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 1-4

ABSTRACT: There are pigs raised for fat, pigs raised for lean meat, and pigs raised for both uses. With the expansion of foreign trade and rising standard of living, the market demand for the lean-meat type pork has been rapidly growing. In order to produce the lean meat type porkers, there are 4 methods to choose from: (1) Raising pure breed or hybrids of the 4 meat porkers already introduced; (2) Breed or cross the province's own fat porkers with foreign species as the province has no native lean-meat type pigs; (3) Reconstruct native fat type pigs and transform them to the meat type; (4) Hybridization using all commercial pigs of the lean-meat type. Following discussions of these methods of breeding lean porkers and factors, such as the nutrition level, the feeding method, and the butchering time, which contribute a great deal to the lean meat content, the paper suggests that in order to produce more lean meat porkers, the province should practice the system of higher purchase price for better quality porkers, establish meat porker production lines, strengthen selective breeding, and enlarge the sources of protein rich feed.

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 4-7

ABSTRACT: In the process of formulating the standard, the emphasis was to study the energy and protein requirements of the meat chickens of local and introduced varieties in the province. The method of biostatistics was employed to analyse and compute the metabolism and protein needs of 3150 seed chicks and 4625 meat chickens to derive a regression equation to calculate the relationship between the daily protein intake and daily weight gain. The result was checked with the National Chicken Feed Standard (draft) and the NRC Standard (7th edition) of the USA. The contents of the experimental standard are reported and discussed, including contents of typical feed mixtures recommended and their contents of nutrients.

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 8-12

ABSTRACT: This paper reports experiments the results of which demonstrate that during certain key stages of growth and development, such as ear-forming [boot] stage, the difference of chlorophyll content between cold and warm weather is great, and the greater is the difference, the poorer is the fruiting rate. Results of α-naphthamine oxide tests and the method of fluid flow quantity (weight) of root wound demonstrate that the lower the temperature the greater is the weight reduction of the fresh root. Results of anthrone method of measuring the soluble sugar contents demonstrate that the sugar content of the spike is higher when the temperature is either suitable or higher. Under low temperature conditions, the sugar content of the spike drops somewhat and its resistance to adversity is also weakened. Detailed data of the experiments are reported.

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 12-15

ABSTRACT: Since 1979, a method has been adopted to start cultivating late rice in the winter in Hainan Island, followed by direct seeding in Guangzhou using short-daylight treatment with shades to produce 3 generations in one year. With this method, basically stable materials may be selected out in 2 years [instead of grow-one generation a year.] Of the new line of late rice thus produced, Qinghuaai expresses good resistance to white withering disease with a relatively high yield, 15 percent higher than the control, Erbaiai. Major technical measures of the 3-generations in one year breeding method are introduced in some detail.

TITLE: "Principle of Cold Tolerance of the Method of Thin Film Seedling Cultivation Without Bud-forcing and the Value of Its Utilization"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 15-18

ABSTRACT: In the past 10 years, the institute has adopted the technique of using plastic film cover to cultivate early rice seedlings without bud forcing (i.e. seeding directly after soaking.) There has been no incidence of dead seedlings even under the severely low early spring temperature condition of 1976 and 78. The method has made it possible to use intermediate ripening varieties of early rice to allow enough time for turning and transplanting the late rice crop after the early rice harvest. Experiments demonstrate that with bud forcing, the bud grows faster than the root to cause the endosperm to be consumed much too fast. This is not favarable for the seedling to develop cold resistance. The use of plastic film creates the favorable condition for the seeds to germinate normally, i.e. without bud forcing and for the seedlings to develop natural and healthy root system which protects the seedlings from the cold temperature.

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 19-21

ABSTRACT: Rice seedling standardization is the key to machine transplanting and growing seedlings in trays is an effective method of standardization. But, seedlings grown in trays without air holes are found to have black-root and yellow-stunt conditions when they are left in the tray until the medium-size stage, i.e. having 3-5 true leaves. The longer the seedlings are left in the tray before transplanting, the more severe are the conditions. This paper reports a study on the relationship between the size of the air hole or the total area of the air holes and the black-root and yellow-stunt conditions of the rice seedlings. It is determined from the study that under the condition of 30 percent air hole area at the bottom of the tray, with hole diameters of 4.8, 6.0, 8.0, or 10.0 mm, the quality of seedlings is close to that of those grown in outdoor open seedbeds. The effect of air hole area is greater, and under the condition of 30 percent area of holes, 4.8 mm diameter holes are best for the seedlings.

TITLE: "A Study on Soil Organic Matter of Major Paddies in Zhujiang Delta"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 22-26

ABSTRACT: Beginning in 1979, the authors carried out a project of fixed position observation and analysis of soil organic matter characteristics of paddies of some major soil types in counties of Zhongshan, Nanhai, Fanyu, Doumen, Xinhui, Dongyuan, and Shunde of the Zhujiang [Pearl River] delta. Findings of the study include the following: (1) Organic matter and nitrogen contents of the sediments and newly diked paddies vary very little to indicate uniformity of parent materials in the delta; (2) In general, the organic matter and nitrogen contents of sugar cane fields are lower than those of rice paddies, yet they are still higher than those of the sediments or newly reclaimed land; (3) Organic matter balance varies a great deal from paddy to paddy to indicate that some paddies are developing in the direction of mature soil and others in the direction of bony thin soil; (4) The oxidation rate of organic matter is higher in sugar cane fields to indicate that an upland cropping environment is more favorable for organic matter conversion than the paddy environment; old organic matter that is difficult to decompose can be found in the paddies. The following effective measures are proposed: (1) Regular applica-

[continuation of GUANGDONG NONGYE KEXUE No 5, 1982 pp 22-26]

tion of organic fertilizer and consistently turning stubble back into the soil; (2) Practice paddy and upland crop rotation to promote material transformation in the soil.

TITLE: "Effects of Different Winter Crops in Dual-season Rice Paddies on Yield Increase and Fertility Nurturing"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 pp 27-30

ABSTRACT: Experiments were carried out from the early season of 1978 to the late season of 1980 in Fushan Prefecture under the condition of cultivating 2 crops of rice a year, to observe the effect of different winter crops, wheat, wheat and green manuure, or beans on soil fertility and the total unit yield. After continuously cropping of these 3 years, the organic matter and whole nitrogen contents of plots of all systems of crop rotation are higher than before the experiment, but regarding nutrient balance, the loss of potassium is very great. In general, there is some gain in nitrogen, a great deal of gain in phosphorus, and a very large loss in potassium. With the rotation system of rice, rice, wheat, a great deal of chemical nitrogen is applied, but the quantity of nitrogen gain is the smallest. With the system of rice, rice, beans [broad bean] the smallest amount of chemical nitrogen is applied, but the nitrogen gain is 0.82 jin/mu higher. With the system of rice, rice, wheat and green manure, the same amount of chemical nitrogen is applied in addition to the green manure, the nitrogen gain is the highest, 4.30 jin/mu, compared with 2.37 jin/mu with the rice, rice, wheat system. An increase of potassium fertilizer application is extremely important, of course, regardless of the crop rotation system.

TITLE: Brief Introduction of a Lean-meat Type Porker--the Hanhua Swine"

SOURCE: Guangzhou GUANGDONG NONGYE KEXUE [GUANGDONG AGRICULTURAL SCIENCES] in Chinese No 5, 8 Sep 82 p 43

ABSTRACT: The Hanhua swine is bred by the institute through hybridization of of a Guanghua mother and Hampshire father. The hybrid Hanhua has only a thin layer of fat on the back. The lean meat rate is 53.53 percent and the daily weight gain is 632.38 g. To gain 1 kg of live weight, the Hanhua swine requires 9130.32 Cal of digestible energy and 353.77 g of digestible protein. The quality of the meat is very good. It is a meat type commercial porker worthy of extension.

TITLE: "Study of Rheological Characteristics for Paddy-field Soil of China (2)--Investigation on Thixotropic Behavior for Clayey Paddy-field Soil"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, 1982 pp 9-15

TEXT OF ENGLISH ABSTRACT: In this paper the paddy-field soil is examined with the extrusion rheometer and is considered to be a thixotropic material. It is found that the thixotropic effect is intensive when the moisture content of the soil is within the range of 40 percent to 70 percent. The empirical equation which expresses the relation between the thixotropic rate and the moisture content of the soil can be presented as follows:

$$T = aw^{b}e^{cw}$$

General aspects of foreign investigations of the soil thixotropic behavior are also mentioned in this paper.

TITLE: "The Influence of Airstream Distribution Along a Sieve on the Separation of Grain Mixture"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, 1982 pp 16-28

TEXT OF ENGLISH ABSTRACT: An analysis has been carried out that indicates that the motional trajectory of grain mixture is influenced by factors such as velocity and direction of airstream, initial velocity and direction of the materials. The velocity and direction of airstream are considered to be main factors. The critical velocity at which the various parts of materials are blown out of the sieve of 1.2 m in length has been calculated. The airstream distribution on a sieve has been analyzed with the new concept that the airstream velocity varies along the sieve and decreases linearly with the height over the sieve. The influence on the separation of three typical modes of airstream distribution is analyzed. Also, the influence of the arrangements of working elements in the cleaning shoe on the airstream distribution and the problems in adjusting the airstream distribution on the sieve by setting the air deflector plates are studied.

TITLE: "Study of Physical and Mechanical Properties on Vibration of Paddy and Wheat Crops"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, 1982 pp 29-41

TEXT OF ENGLISH ABSTRACT: A number of research works have verified that crops in a head-feeding threshing cylinder have a vibratory form of motion. The physical and mechanical properties of vibration for paddy and wheat crops have been researched, and measurements have been taken for geometrical dimensions relating to vibration, weight, rigidity, damping, etc. The natural frequencies and normal vibratory modes in ear and stalk systems for some lower steps under varied conditions (depending on varied boundary conditions) were measured. Theoretical calculations and analyses were made using a mathematical mode on a computer. The results of the tests and theoretical calculations indicate that, similar to the physical and mechanical characteristics of the crops, the performance of mechanical vibration is also one of inherent properties for each crop and has definite statistical regularity. It is important to explore these properties and apply them to the principles of a head-feeding threshing machine.

TITLE: "Experimental Research on Tooth Bearing of the Spiral Bevel Gears of Tractors"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, 1982 pp 42-52

TEXT OF ENGLISH ABSTRACT: When the setting of a pair of spiral bevel gears, such as its mounting distance, shaft offset and shaft angle, etc., was changed, its tooth bearing varied in some way. In this paper, the patterns of the tooth bearing variation of Gleason and Oerlikon spiral bevel gears for tractor (or automobile) main driving were studied and summarized, and a criterion for determining the direction of the shift of the tooth bearing along the tooth width was advanced. Based on the loading test for both types of spiral bevel gears on the "Dongfanghong-75" tractor, the patterns of the tooth bearing variation under loading were presented.

TITLE: "On Suitable Fitting of Centering Surfaces Between Mating Spline Parts in Agricultural Machinery"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, 1982 pp 53-62

TEXT OF ENGLISH ABSTRACT: A study on the working behavior of centering surfaces between mating spline parts is made in this paper by means of the analysis of kinematics and dynamics of the spline parts when the axes of the two mating parts (the spline shaft and the coupled gear) slope, the measurement of axial thrust at the gears coupled with the spline shaft in the gear box under both laboratory and field test conditions, and the statistical analysis of information from practical applications on several models of tractors. The results show that the gears on which the teeth are located at either end (or at both ends) of the spline hub will slope with respect to the axis of the spline shaft due to the existence of clearance between fitting surfaces when the gears are being loaded and this slope will cause a relative axial slide between the mating spline parts when the parts are rotating around their axes. Add to this the uneven distribution of the tangential forces at the spline teeth and the effect of friction in contact surfaces,

[Continuation of NONGYE JIXIE XUEBAO No 3, 1982 pp 53-62]

and an axial thrust and movement of the coupled gears will occur. When the clearance increases up to a certain limit, for instance, to 0.07 - 0.1 mm for a shaft diameter in the range of 30-50 mm, the axial thrust will increase and that will cause severe wear on the contact surfaces of both the spline teeth and the gear shift forks, and self-disengaging of the shift gear from its meshing position may happen when the tractor is working. According to the requirements of application and processibility of the splines with hard broached holes, the authors suggest suitable fitting of centering surface between mating spline parts for different construction and working conditions.

TITLE: "Development of a Science of Agricultural Mechanization on the Basis of A Chinese Style Mechanization of Agriculture--Beginning With a Review of the Process of Agricultural Mechanization in Heilongjiang Province"

SOURCE: Beijing NONGYE JIXIE XUEBAO [TRANSLATIONS OF THE CHINESE SOCIETY OF AGRICULTURAL MACHINERY] in Chinese No 3, Sep 82 pp 1-8

ABSTRACT: Comparing the results of 30 years of agricultural mechanization in Heilongjiang Province with these in the USA and Japan, the author maintains that agricultural mechanization obviously failed in Heilongjiang Province in terms of reducing the number of draft animals and the farm population and in terms of increasing the income of farmers. Although the USA is a country of large land and small population while Japan is a country of small land and large population, agricultural mechanization succeeded in both countries in those terms. The author claims that the failure is due to insufficient coordination of related departments of the national economy. The supply of some machines is not in line with the demands, and there has not been serious study and development of a science of agricultural mechanization. Such a science should contain the following: (1) A system of agricultural machines; (2) Energy sources for agricultural production; (3) Operation and management of agricultural mechanization; (4) Extension and service of agricultural mechanization; (5) Economics of agricultural mechanization. With the development of that kind of science, a Chinese style agricultural mechanization may emerge to cause it to be specially suitable for the Chinese condition of

[continuation of NONGYE JIXIE XUEBAO No 3, 1982 pp 1-8]

being a socialist country of little per capita natural resources and weak foundations of economy and industrial and agricultural technology. In the viewpoint of the author, the Chinese style agricultural mechanization should possess the following major characteristics: (1) An outlet should be arranged for every farm labor displaced by agricultural mechanization; (2) The chief goal should be yield increase and energy saving; (3) The capital for agricultural mechanization should come from a combination of self-reliance of communes and brigades and State financial assistance. The key is suitable techniques instead of a hurry pursuit of total mechanization. Consideration must be given to the interests of all 3 sectors of the State, the collective bodies, and the individuals. Some farmers should be allowed to get rich first, yet, the wealth of all must also be the goal.

SOURCE: Dalian ZIRAN ZIYUAN [NATURAL RESOURCES] in Chinese No 3, Sep 82 pp 9-11

ABSTRACT: On the basis of soil surveys and forest surveys, the 90-thousand-character volume, TAIHE COUNTY COMPREHENSIVE AGRICULTURAL REGIONALIZATION, JIANGXI PROVINCE has been compiled. Its major contents are outlined in the paper. The abundant resources of light, heat, and water of the county are favorable for the growth of many types of subtropical plants. There are 1.255 million mu of forest cover but very few grasslands. Only about 1/5 of the county is cropland and the mountains and hills are poorly utilized, leaving a great potential for development. The regionalization plan (map included) divides the county into 5 agricultural regions: (I) Timber forest region of western mountains and hills; (II) Grain and oil producing tree region of hills and plain to the west of Ganjiang river; (III) Economic crop region of Ganjiang river valley plain; (IV) Grain and oil producing tree region of the hills to the east of Ganjiang; (V) Timber forest and oil tea [Camellia oleifera Afel.] region of the mountains and hills in the southeastern part of the county. Detailed development plans are also outlined in the paper and discussed.

TITLE: "Preliminary Evaluation of Water Resources of Beijing City"

SOURCE: Dalian ZIRAN ZIYUAN [NATURAL RESOURCES] in Chinese No 3, Sep 82 pp 12-20

ABSTRACT: In recent years, water consumption has been increasing rapidly in Beijing City. The phenomenon of various users competing for water occurs frequently. It is high time to give an accurate evaluation of the city's water resources. On the basis of a study on the transforming relationship of runoff of Haihe and Kuanhe valleys, the paper fully utilizes all available survey data and research results, to compute the atmospheric precipitation, the stream runoff, the ground water supplement to produce a multi-year average quantity of water resources in Beijing of 56.6 hundred million m^3. After calculating the water consumption of agriculture, industries, and the city's inhabitants, the paper concludes that in an average year, the supply and the demand can reach a balance and Beijing may even provide 6 hundred million m^3 of water to Tianjin. In years of shortfall, Beijing not only cannot supply Tianjin with water but also will be 4 hundred million m^3 short in the first year. Ways must then be found to restrict water use for agriculture. If drought continues for 2 years, the deficiency will be 14 hundred million m^3. Development and utilization of water resources have reached a very high level in Beijing. Measures to be taken to manage the current new stage of determining the needs according to the supply are discussed.

ITLE: "Preliminary Study on Scientific Ways of Transferring the Water of Huanghe"

OURCE: Dalian ZIRAN ZIYUAN [NAUTRAL RESOURCES] in Chinese No 3, Sep 82 pp 21-29

BSTRACT: In an average year, Huanghe has a water volume of 480 hundred million m^3 and carries 16 hundred million tons of silt. By 1980, more than 200 hundred million m^3 of its water was used to irrigate 50 hundred million mu of cropland and there remained 200-300 hundred million of its water draining into the sea. As there is no other source of irrigation water for the banks of Huanghe, transferring its water is a necessity, but in the lower reaches, Huanghe flows above the ground and its small branches are basically seasonal drainage channels; therefore, in this area the only source is ground water, which must be locally supplemented. In many places, the round water has been used beyond the quantity of local supplement to cause obvious rop of the water table, and transferring the water of Huanghe to recharge the gound water has become an urgent necessity. This paper analyzes these and other situations and suggests scientific ways of using the water of Huanghe along with its silt to reconstruct large areas of saline and alkaline lands in Kaifeng and Shangqiu, for example, where 2-3 million mu of such wasteland are awaiting development.

TITLE: "Rate of Precipitation Variation of Ten-day Periods During the Flood Stage of May to September in East China"

SOURCE: Dalian ZIRAN ZIYUAN [NATURAL RESOURCES] in Chinese No 3, Sep 82 pp 51-58

ABSTRACT: In China, especially East China, precipitation is influenced mainly by monsoons and about 1/2 to 2/3 of the annual rainfall is concentrated in the summer, which is the key period of crop growth. The amount of monsoon rains basically determines the amount of yield. Chinese scientists had studied the rate of variation of monsoon rains in the 30's and 50's but mainly on annual and monthly variations. Based upon long term precipitation data of the Central Weather Bureau, the author selected the records of 110 weather stations located to the east of 100° E. Long, and 20-50° N. Lat. The data analyzed are for the 15 10-day periods of May-Sep in the 24 years of 1952-1975. Judging from the spatial distribution of the rate of variation of 10-day periods, the changes appear to be gradual and may be generally divided into 4 types. The maximum variation rate and the minimum variation rate are computed and locations of their axes defined. The movement of the axes is found to be related to the northward advance and southward retreat of the subtropical high pressure system.

TITLE: "Analysis of Supply and Demand of Water Resources in North China Plain"

SOURCE: Dalian ZIRAN ZIYUAN [NATURAL RESOURCES] in Chinese No 3, Sep 82 pp 77-87

ABSTRACT: The N. China plain is frequently visited by natural calamities, which commonly seem to be mostly droughts. Analysis of historical records reveals that on the average there is one drought every 2.6 years and one particularly severe drought every 55 years, but there is one flood every 1.5 years and one particularly severe flood every 16 years. Through an analysis of supplies and demands of many years, the authors conclude that with some additional reservoirs in the mountainous as well as the plain areas of N. China, about 40 hundred million m^3 of water supply may be added; therefore, a 75 percent rate of supply for a medium severe drought year can by basically guaranteed if water-source constructions within N. China itself are completed. The paper proceeds further to analyze the water volume of Changjiang during the dry season to demonstrate that transferring water from S.China to the north may not be feasible, at least not in the next 10-20 years. In the long run, feasibility of the project will have to be determined by the water needs of the north, the amount of water of the Changjiang capable of being stored, water needs for treating saline and alkaline lands, changes of the estuary of Changjiang, and the economic capability of the nation.

I. GENERAL INFORMATION

BUMPER EARLY RICE CROP REPORTED

Beijing ZHONGGUO NONGMIN BAO in Chinese 26 Sep 82 p 1

[Article: "Early Rice State Purchase Quotas Overfulfilled Throughout the Country. In Some Prefectures Have Appeared a Group of Households That Have Sold the State 10,000 Jin of Early Rice From a Single Crop, Production Teams That Have Fulfilled Their Total Annual Purchase Quota in a Single Season, and Production Brigades That Have Sold 1 Million Jin of Early Rice to the State in a Single Season"]

[Text] According to statistics as of 20 September from 10 early rice producing provinces and regions, early rice now stored in granaries overfulf-lls state procurement plans by 107.2 percent. As compared with the same period last year, speed has been faster, quality of grain in storage is better, and quotas were fulfilled 5 days earlier. The provinces and regions of Guangdong, Guangxi, Fujian, Jiangxi, Hunan, Hubei, and Zhejiang overfulfilled purchase quotas. Statistics as of 15 September show that in Hunan and Guangxi 1.1 billion jin more of early paddy (converted to husked rice terms) has been placed in storage than during the same period last year. Fujian Province overfulfilled early rice procurement quota by 22.3 percent, and Hubei by 20 percent. In Jingzhou Prefecture, Hubei Province, 397 commune member households sold the state 10,000 jin of early rice in a single season; and 4,415 production teams completed their purchase quotas for the entire year in a single season. Eight production brigades in Chuandian Commune in Jiangling County sold to the state more than 1 million jin of early rice in a single season.

This year the early rice in some prefectures sustained serious damage from the elements and cadres and commune members, working under the guidance of CPC committees and the People's Government at all levels, actively joined the struggle against disaster. They intensified late stage field care, reduced losses from disasters, and brought in a bumper early rice crop. Following the bumper harvest, acting on the principal of concurrent concern for the interests of the country, the collective, and individuals, the People's Government everywhere distributed state purchase quotas equitably. In reaping a bumper harvest, the broad masses of peasants did not forget the loving care shown by the party and the support provided by the country, and they used real actions to hail the victorious opening of the 12th Party Central Committee for a heartening situation of greater sales of surplus grain for greater contributions.

Everywhere business, supply and marketing, industrial and commercial administration, railway, communication and transportation departments actively worked together to make possible quick movement into storage of the early rice. Grain departments actively solved difficulties in selling grain and receiving grain. They used methods that provided convenience to the masses such as numerous individual households selling their grain directly for a preliminary change in the past passive situation.

CONTAMINATION OF GRAIN IN TRANSIT WORSENS

Zhanjiang Port Major Offender

Beijing RENMIN RIBAO in Chinese 21 Sep 82 p 2

[Article by Transportation Management Department, Grain Storage and Transportation Bureau, Ministry of Commerce]

[Text] Recent grain shipments into Yunnan, Guizhou, and Guangxi have been seriously contaminated while being transported by railroad, and some shipments have been inedible.

In May this year, the Kunming Municipal Xishan Grain Transfer Station received 81 carloads of corn and wheat from Zhanjiang Port that had been shipped in cars 40 percent of which had not been swept out. On the floors of most cars were coal cinders and coal dust. On 17 May, the Guiyang Municipal Oil and Grain Storage and Transportation Company received a carload of wheat from Zhajiang in a car in which coal dust was 1 to 2 centimeters deep. Not only had the storage bags been blackened, but 158 jin of wheat spread inside the car had become black wheat. In cars containing a wheat shipment from Zhanjiang received by the Nanning Municipal Wheat Flour Mill there was quite a lot of coal ashes and gravel. Annually anywhere from several hundred to as much as 1,000 jin of grain is contaminated. Between January and June this year, the Zhanjiang Port Grain Transfer Station shipped 6,151 carloads of grain to Yunnan, Guizhou, Guangxi, and Hunan provinces, 5,100 of the cars used being open-top hopper cars, virtually none of which had been swept out. Sweeping of cars should be the responsibility of the unloading unit, but neither the port nor the railroad units care.

Contamination of grain by chemical fertilizer and pesticides is also very serious.

We cannot see the country sustain grain losses with indifference. I call upon the railroad, transportation, and grain sectors to solve the problem of grain contamination in transit with all possible speed.

Grain Shipment Contamination Analyzed

Beijing RENMIN RIBAO in Chinese 21 Sep 82 p 2

[Text] The problem of grain contamination while being shipped by rail is an old one that has not been solved for many years. Recently, the understanding of the situation that we got from railway departments is far more serious than the situation as we understood it from the Grain Storage and Transportation Bureau of the Ministry of Commerce. The soybeans, rice, wheat, and corn contaminated last year during rail shipment totaled 800 tons. During the first half of this year the amount increased to 1,420 tons. Some grain had urea and animal dung sticking to it, and some of it had a strange taste or had changed color and was inedible.

During the past several years, leadership comrades concerned in the State Council have held several meetings on this subject, and the Ministry of Commerce, the Ministry of Railways, and the Ministry of Transportation all have clear instructions about prevention of grain contamination. Nevertheless, numerous transportation departments and grain loading units have not conscientiously put them into effect.

Comrades in railroad freight transportation departments have said there are four reasons for grain contamination as follows:

One is failure to implement personal responsibility systems. Freight handling units charged with unloading of coal and chemical fertilizer do not sweep out the cars following unloading as regulations require, or when freight cars have been contaminated with strange smells, the railroad station makes no inspection and outgoing grain is loaded on the cars before they have been scrubbed down. Grain departments also frequently do not inspect in the way that regulations require. When they find cars do not meet specification, they neither make arrangements to change cars nor do they sweep them clean. Instead they put some bedding in them and load grain.

Secondly car disinfecting equipment is inadequate. According to regulations, when railroad cars have been contaminated by pesticides or other toxic materials or contain noxious odors, they must be scrubbed down and disinfected before being used. Today only 21 branch bureaus among the country's 60-odd railroad branch bureaus have places for scrubbing and disinfecting cars. Several such as Fengtai, which had disinfecting sites, closed down because of inability to handle polluted water and pollutants.

Third, is inability to assign cars specially to the hauling of toxic materials. According to regulations, special cars are to be used for the transportation of toxic materials, and after they have been used toxic materials cars are to be put in the custody of custody stations. In 1980, the Ministry of Railways assigned 2,000 cars specifically for the hauling of toxic materials, but most of them require major repairs. The number of cars used specifically for the hauling of toxic goods is small, and there is no fixed way of looking after them. When an urgent situation arises, they are still used indiscriminately.

Four, is poor quality of chemical fertilizer and pesticide containers. Nationally produced pesticides and chemical fertilizers are packed either in paper or plastic bags, the quality of which does not meet specifications. This plus "savage loading and unloading" means a very high breakage rate.

Some comrades suppose that the fundamental reason is that both the railroad and affiliated units pay attention only to quantity while ignoring transportation quality.

For many years the problem of grain contamination has received no serious attention. The danger it poses to the people's health cannot be expressed adequately in simple figures. It seems that the time has come for conscientious solution of this problem.

NATIONAL SOIL FERTILITY TEST CENTER ESTABLISHED

Beijing ZHONGGUO NONGMIN BAO in Chinese 26 Sep 82 p 1

[Article: "China Sets Up Modern Soil Fertility Testing Center"]

[Text] A soil fertility testing center intended to serve national agricultural research and production was recently established in Beijing and has formally begun trial operation.

This testing center, whose structure covers a 5,100 square meter area, has been built on the grounds of the Chinese Academy of Agricultural Sciences' Soil Fertility Institute. It has modern large scale precision instruments and equipment, and uses electronic computer control and automated analysis. It is capable of analyzing and testing 100,000 samples annually in about 500,000 operations. This testing center was designed by using the method of importing foreign technology and principal equipment that was adapted and augmented in accordance with China's circumstances. This method was both suited to China's circumstances and saved a very large amount of funds. The investment required was half what it would have been had all equipment been imported.

This testing center is the first of nine major agricultural research facilities to be built. It is the third agricultural research base built following completion in May this year of the Hubei Provincial Academy of Agricultural Sciences' Testing Center and expansion of the Guangdong Provincial Academy of Agricultural Sciences' Paddy Rice Institute.

USES OF AIRCRAFT IN AGRICULTURE OUTLINED

Beijing RENMIN RIBAO in Chinese 14 Oct 82 p 2

[Article: "Rapid Increase in Volume of China's Agricultural Air Operations"]

[Text] Since the Third Plenary Session of the 11th Party Central Committee, great development of China's agricultural aviation has taken place. A group of new tasks has been successfully undertaken, and year after year production flying hours have overfulfilled plan. During the past 3 years civil aircraft have carried out more than 80 operationsin more than 20 of the country's provinces, municipalities, and autonomous regions flying an accumulated more than 80,000 hours. Their farmland area of operationscovered more than 70 million mu; aerial afforestation and planting of grass covered a more than 28 million mu area; and more than 15,800 hours of flying was done for forest protection, a forest area of more than 800 million mu being patrolled annually. Number of hours flown for agriculture increased an average 79 percent over 1978, andin both 1980 and 1981 than 28,000 flying hours were logged for an all-time high.

Every year China's agriculture sustains fairly heavy losses as a result of disease, insect pests, weeds, and rodents. During the past 3 years, a 56 million mu area of farmlands, forests, grazing lands, and orchards has been aerially treated to control insects, effectively preventing and controlling damage from several tens of insect species including migratory indigenous locusts, voracious armyworms, destructive pine moths and suddenly occuring snout moth larvae.

During dry seasons, aircraft engaged in rain making for remarkable results in combat against drought to protect seedlings and to reduce danger of forest fires. During the past several years, annually more than 10 aircraft have carried out rain-making operations over 10 provinces, municipalities, and autonomous regions, rain-making sorties amounting to 70 percent of the total number of sorties for operations of all kinds. Rainfall increased by from 20 to 50 percent over an area of about 350,000 to 400,000 kilometers.

Use of aircraft to carry out leaf fertilization of crops and spraying of plant hormones has rapidly increased since 1979. In northeast, north, and east China, this has become a major way in which to increase yields for numerous state owned farms. Annually nearly 100 aircraft are engaged in such operations nationally over an operational area of more than 10 million mu.

Aerial sowing of seeds for afforestation has become a major way of greening remote barren mountains. During the past 3 years, the area sown has increased at an annual 74.6 percent rate over 1978. In addition to the continued large area sown in southwestern and south China, aerial sowing has also spread to south central, east, northwest, and northeast China.

Since 1979, experiments have been conducted in newly launched aerial sowing of pasture grass on barren mountains, barren plains, andgrassy slopes in 44 counties (or banners) in 16 provinces, municipalities, and autonomous regions including Hunan, Shaanxi, and Nei Monggol. As of the end of 1981, 50 aircraft had flown a total of more than 1,500 hours to sow more than 1.2 million mu of pasture grass for a full stand rate of about 50 percent.

In the field of aerial forest protection, as a result of the use since 1979 of helicopters to transport fire fighters on air drops to put out fires, and the use of AN-5 transports to carry fire-extinguishing chemcials, the discovery rate for fires and results in extinguishing fires have risen markedly.

SPURT IN FRESHWATER FISH RAISING REPORTED

Beijing ZHONGGUO NONGMIN BAO in Chinese 20 Sep 82 p 1

/Article: "Nation's Freshwater Fish Raising Continues Growth. More Than 540,000 Mu of Commodity Fish Bases Set Up by State; 1.8 Million Commune Member Households Raising Fish"/

/Text/ The country's rural raising of freshwater fish continues to grow. Statistics from 18 freshwater fish raising areas nationally show that during the first 8 months of this year, output totaled 568,000 tons, a 35,000 ton increase over the same period last year.

By way of meeting the struggle objective set by the Central Committee Secretariat for national production of between 4 and 5 million tons of freshwater fish by the end of the 1980's, this year all provinces, municipalities, and autonomous regions have effectively strengthened leadership of freshwater fish raising, treating it as a major matter in economic diversification whereby peasants can become prosperous with all possible speed, and solving problems with capital, skills, and food supply for raising fish. Yunnan Province has decided that beginning this year it will annually obligate 5 million yuan to development of freshwater fish raising. The Hunan Provincial CPC Committee has decided to revive and build aquatic products technical promotion stations in the province's 22 hill counties, and to increase personnel from 500 to 1,050. Many places have put into effect a system whereby 1 jin of feed grain is supplied for each jin of fish purchased.

In order to increase the water surfaces utilization rate and raise yields per unit of area, all jurisdictions have vigorously promoted new techniques for raising fish. Raising of fish in mesh cages has become popular and has spread fairly rapidly. Provincial and municipal statistics for June 1981 showed this method used on only 484 mu, but this increased to more than 1,400 mu this year. Quite a few places have promoted use of pellet feed for fish. Last year this was done on 3,100 mu in Shanghai, and the area has doubled this year. Yields have risen from the somewhat more than 400 jin per mu of the past to somewhat more than 1,000 jin, and to a maximum of somewhat more than 4,000 jin. Guizhou, Hunan, Hubei, Sizhuan, Jiangsu, and Guangxi provinces have revived and developed the raising of fish in paddy fields. Last year the paddy field area used for this purpose was 2.2 million mu; this year it has increased by another 200,000 mu.

All jurisdictions have continued to liberalize fishing industry policies and to further designate and clarify water surface use rights so that the country, collectives, and individuals will all benefit. This year's commodity fish bases built by the state that have gone into production cover 548,000 mu. Progress in local building of commodity fish bases has also accelerated everywhere. Raising of fish by commune member families has also grown rapidly. Last year households engaged in the raising of fish numbered 1.3 million nationally, but this year the number has grown to 1.8 million, and in quite a few communes and brigades every household is raising fish.

FINAL TESTS OF NEW IMPROVED WINTER WHEAT VARIETY UNDER WAY

Beijing BEIJING RIBAO in Chinese 15 Sep 82 p 3

[Article: "Superior Winter Wheat Variety Jinghua No 1 Successfully Bred in Beijing. Hu Daofen [7579 6670 5358] and Others Work Hard at Breeding Using Haploid Breeding Method. Great Bumper Yield Potential; Fairly Broad Adaptability; Suited to Rapid Promotion From Existing Foundation"]

[Text] Jinghua No 1, the first rather good superior winter wheat variety suitable for production planted that has ever been bred in China or abroad using the haploid breeding method was declared a success following recent evaluation by Chinese experts concerned. This is the fruit of more than 6 years of arduous efforts on the part of assistant researcher Hu Daofen and others at the Crop Institute of the Beijing Municipal Academy of Agricultural Sciences. This year Jinghua No 1 was test planted at 18 experimental sites in Beijing's suburbs, an overwhelming majority of which produced high yields. Among them was the test planting on 3.16 mu at the Nanjanji Production Brigade where yields averaged 1022.4 jin per mu.

The work of breeding Jinghua No 1 began in 1976. Comrades engaged in the breeding used the pollen haploid breeding method. Four wheat varieties that included "Luofulin 18," "5328 - 036," and "Hongliang No 4" were aggregately hybridized, the pollen from the first generation resulting from the hybridization being cultured for successful harvesting of first generation seeds. In 1978, Hu Daofen and the others used the only 54 seeds they had to evaluate the plant line. As a result of their painstaking propagation, Jinghua No 1 increased gradually in numbers and the scope of experiments expanded year by year. In 1981 Jinghua No 1 participated in medium fertility group regional assessment tests of wheat varieties in Beijing where it took first place among 14 varieties in yield, yields averaging 705 jin per mu, 16.9 percent higher than for "Nongda 139." This year it participated in high fertility group regional assessment tests of wheat varieties in Hebei Province, where it produced highest yields, demonstrating this variety's adaptability when grown elsewhere. Not long ago at a national academic conference for exchange of experiences on wheat another culture and its genetic breeding, which was attended by the country's breeding specialists, an evaluation of Jinghua No 1 was made. They acknowledged the overall superiority of Jinghua No 1 variety, its tillering strength, its high spiking rate, the eveness of its spikes, its many blossoms and many grains, the light color of its grain, its strong disease resistance, its high resistance to powdery mildew, its high resistance to stalk, leaf, and stem rust, the semi-squatness and toughness of plants, its resistance to lodging, as well as its rather strong ability to withstand cold and hot dry winds. The experts agreed that this variety possesses high potential for bumper yields, that its adaptability is rather wide, and that demonstrations should be expanded on the basis of what has already been done, and promotion accelerated.

The successful breeding of Jinghua No 1 not only provides a better superior variety for future winter wheat production in Beijing's suburbs, but also opens a whole new avenue for scientific breeding work. Comrades who had a part in the breeding of Jinghua No 1 beleive that as compared with conventional breeding methods, breeding that uses the haploid breeding method is superior in that it can compress the breeding generations, improve selection efficiency, and conserve manpower and land. At the present time this is an advanced breeding method both in China and abroad.

On 7 August municipal departments concerned held a conference that called for a good job in breeding of Jinghua No 1. This fall the city plans to sow 7,000 mu of Jinghua No 1 wheat, and after a large quantity of superior variety seeds have been obtained, it will promote its large scale cultivation in Beijing's suburbs.

ECONOMIC EFFICIENCY IN EXPANDED COTTON PRODUCTION

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 7, 1982 p 3-6]

[Article by Mei Fangquan [2734 2455 2938]: "A Discussion on Building Economic Efficiency in the Huanghai Plains Cotton Growing Region"]

[Text] The vast Huanghuaihai plains are the nation's largest production area for wheat, corn, cotton, peanusts, sesame and tobacco. The plains are located south of the Great Wall, north of the Huai river, and east of the Tai Hang and Yuxi mountains and include most of Beijing, Tianjin, most of Hebei province, most of Shandong province and the portions of Anhui and Jiangsu which lie north of the Huai river. The plains have a total area of 380 million mu, with 271 million mu of arable land, the land reclamation index is 70 percent and the agricultural population is 139 million people, with farmers occupying 1.95 mu of arable land per person. The present level of production is relatively low so there is great potential for increased production and there especially is a great future in development of cotton growing.

An Analysis of the Cotton Region's Economic Potential

In the mid 1950s, the Huanghuaihai plains were a relatively centralized cotton region, with over 30 percent of the arable land in most of the countries w.th concentrated cotton production given over to cotton fields, and with a few centralized counties having over 50 percent cotton fields. In 1956, cotton fields for the whole area stood at nearly 40 million mu, with total production reaching over 11 million dan, about 40 percent of total national production. For the next 20 years, not only were there great reductions in the cotton field acreage, for a long time the quantity and quality of production were stagnant and even declined. By 1979, the total cotton field acreage had declined to 25.6 million mu, ginned cotton production was only 9.04 million dan, 35 jin of cotton per mu, with a total pr2duction value of only 1.1 billion yuan.

In 1980, there was a great turnaround in cotton production. The entire area of 28 million mu of cotton fields had total output of 24 million dan, 85.7 jin per mu, an average increase of 1.7 times over the previous year. Far above the highest historical level. Total gross value, calculated for that year's standard prices, was 4.3 billion yuan, 3 times the previous year.

This brought great improvement to the lives and the production of the people of northeast Shandong, eastern Henan, and the plains north of the Huai river, so long subject to natural disasters and having low production levels.

According to the tentative plans made by the provinces and municipalities in this region, by 1985 the cotton fields for the entire region can be expanded to 50 million mu, occupying 20 percent of the arable land (40 percent in the Liaocheng area), with 100 jin of ginned cotton per mu and total ginned cotton production of 50 million dan. If this plan can be carried out there then will be great improvements in economic efficiency, as shown below:

(1) There will be full utilization of land resources, promotion of mutual progress for grains and cotton and increased production for both cotton and grains. This region has relatively abundant land resources, the land is level and basically is a plain at over 100 meters above sea level, the earth is thick strata, most of it is slightly alkaline tideland which is suitable for growing cotton and which, moreover, is suited to large-scale mechanized agriculture. The ratio of people to arable land is rather low, and the low-lying eastern plains have 2.28 mu of arable land per person. At present, the entire region has over 50 million mu of saline-alkali wasteland awaiting management and full utilization. Of this, there is 12 million mu of saline-alkali soil in northwestern Shandong alone which needs to be developed. If positive conditions can be created to make full use of this land, use the seed variety "Zhongmiansuo No 10," and implement a two-crop grain and cotton harvest system, then it will not be necessary to reduce the present grain field acreage and cotton can be used to accelerate grains and achieve both increased cotton and grain production. At present, the level of grain production in this region is still not high. The year 1979 yielded the highest level of foodgrain production, with 560 jin per mu of cultivated land, with 330 jin per mu of the sown area. If the area's acreage of cottonfields is expanded to 50 million mu, this not only will directly raise the current production level of 24 million dan to 50 million for the entire region, the overall production valuewill raise from the current production level of 24 million dan to 50 million for the entire region, the overall production value will raise from the current 4.3 billion yuan to 9 billion yuan. Moreover, there will be 11 billion jin of cottonseed oil, 8 jin per person. Each mu of cotton field can use 165 jin of cottonseed cakes, which will provide a 100 jin bonus of chemical fertilizer. The use of this fertilizer and the capital along with developments in animal husbandry will make it entirely possible to produce an additional 100 jin of grains per mou over the present production levels. In this way the region will have increased grain production of 20 billion jin. This not only will guarantee the continual increase of cash crops such as cotton, it moreover can make this region into a new community grain base for the nation.

(2) Because cotton production in China was stagnant for such a long time, there are contradictions between supply and demand so that every year, there is a need to import large amounts of raw cotton. In 1980 alone, there were 18 million dan of cotton imported, equal to one-third of the nation's total cotton production, at a cost of 1.7 billion US dollars of foreign exchange, This year, if this region does not produce nearly 15 million additional dan of ginned cotton, the state will then have to pay out another 1.4 billion

in foreign exchange to import even more raw cotton. If, by 1985, the 15 million mu of cotton fields in this region attain production of 100 jin of cotton per mu (total national production of 80 million dan of ginned cotton) we then will not have to import any cotton at all. Moreover, predictions show that there will be cotton goods exports which use up at least 20 million dan of cotton. According to current pricing for exports of cotton goods in the textile industry, this will produce an annual return of over 3 billion US dollars.

(3) Following the development of comprehensive utilization of the processing industry for agriculture and sideline products in the cotton growing region there can be processing of food products from cottonseed oil. The cottonseed shells can be used to raise mushrooms, tremella and glossy ganoderma. The cottonseed husks and the stems can be used to make synthetic fibers for rope and paper, stems can be pressed into fiberboard, stem cores can be used to make paper, and cotton phenol can be used in medicines. If the toxic elements in cottonseed kernels can be removed quickly enough, then 8 billion jin of cottonseed kernels can be used to make various high protein foodstuffs. This will greatly increase the economic income of people in cotton growing regions.

(4) After there are large increases in cotton production, there will be sufficient materials for the cotton ginning equipment and the nation's textile plants which can process 80 million dan of ginned cotton. With increases in high-grade textile products there will be rapid development of the clothing industry, which will provide employment for several million workers. Building a new textile production center in North China will bring basic changes to the Huanghuaihai plains where most areas have low production and suffer from national disasters. Moreover, this will bring about a new situation in our cotton production processing and textile industries and in the clothing industry.

The Promotion of Ecological and Economic Superiorities

The Huanghuaihai plains are ecologically and botanically the most suitable cotton growing region in China. Cotton growing in an ecologically suitable natural environment generally makes it easy to obtain the best results in production quantity and quality, and permits development of the superior natural ecological conditions found in that locale. And the presence of fine social, economic and technological conditions also permits full utilization of the region's superior conditions.

(1) Superior natural ecological conditions. This region has a relative abundance of light, temperature, water and land resources. First, it has 4,000-4,500 degrees centigrade [sic] of active accumulated temperature at 10 degrees centigrade, which clearly exceeds the requirements of intermediate maturing upland cotton; there are 175-220 frost-free days; the north cannot attain two harvests but the south does so easily. However, only slightly more than 10 percent of the cotton field acreage now has two harvests, so the productive season is not being fully utilized. Next, there are 2,200-2,900 hours of annual solar radiation and there is ample solar radiation in spring and cotton boll opening. However, at present, the utilization rate of solar energy

in an ordinary year is only 0.1-0.2 percent. Third, the annual rainfall is about 500-800 millimeters, the rainy and hot seasonsoccur together in summertime and meet the moisture requirements of cotton during the period of greatest growth and developments of cotton during the period of greatest growth and development. There is an uneven distribution of surface water and underground water, but the broad plains have conditions which generally permit the development of irrigation. The rivers and streams have a flow of about 120 billion cubic meters, more than 400 cubic meters per mu of arable land. There are about 40 billion cubic meters of supplemental underground water, about 150 cubic meters per mu. There are about 9 billion cubic meters of salt water. However, because of the low ratio of plant and forest cover there is only a short season for cover vegetation so that relatively large amounts of soil moisture evaporate and there is proportionately little benefit derived from this moisture. There is much runoff in the rainy season and very little water accumulation, so there is incomplete utilization of water resources. Because of the good light, temperature, water and land resources this region, early in the 1970s, it first began to reach ginned cotton production of 100 jin per mu, which was attained in Changwei prefecture of Shandong province, for example. Xinxiang county in Henan Province produced 140 jin of ginned cotton per mu and some brigades managed to produce as much as 150 jin per mu. Such evidence demonstrates that this region has great potential for the development of cotton production. Of course, there also are a number of disadvantageous natural factors. For example, there are frequent cool springs and early autumn frosts, there frequently are both spring drought and summer floods in the same year, and the summer rainfall is too concentrated, which causes many cotton bolls and buds to fall off. But experience in other regions shows that these problems can be solved by improved cultivation techniques.

(2) Superior social, economic and technological conditions. This region has at least 600 years of cotton growing history and as an old cotton region the cadres and masses therefore have long-term cotton growing experience. This region is located in the central plains with convenient transportation and communications. Between north and south there are the Beijing-Guangdong railway and the Beijing-Shanghai railway. Between east and west there is the railway from Gansu to the seaboard, ending at Lianyunjiang. Moreover, there is a network of public roads. The network for cotton purchase and processing extends throughout the entire cotton region and relies on cotton ginning capabilities of Hebei, Shandong and Henan. According to calculations, 45 million dan can be processed in 6 months. The textile mills of these three provinces have over 3.3 million spindles which can use up more than 12 million dan of raw cotton per year. During the past two years, total cotton production did not reach 10 million dan, which led to shipments of cotton from south to north and incomplete use of the cotton ginning and weaving capacity. If cotton planting for the entire region reaches 50 million mu, it will then be possible to utilize the above-mentioned superiorities.

A Path for Implementing Economic Growth

In order to fully develop the natural ecological economic and technological superiorities of the Huanghuaihai plains and struggle to implement the plan for economic growth in the expanded cotton region it is necessary to carry out the following tasks.

(1) Hasten the transformation from one harvest to two harvests and implement crop rotation of wheat, oils and green manure. For the last 10 years, 15 percent of the cotton fields in this region have had a two harvest system of wheat (oils) and cotton, and Shijiazhuang prefecture in Hebei reached 80 percent. In Henau, the prefectures of Zhoukou and Xinxiang reached 40 percent. The improved variety "Zongmiansuo No 10" has provided new conditions for implementing two successive crops or interplanting of wheat (oil or green manure) and cotton. Ongoing large-scale experimental planting demonstrates that planting successive crops of "Zhongmiansuo No 10" and wheat can produce over 500 jin of wheat and over 100 jin of ginned cotton per mu per year. The whole region has 50 million mu of cotton fields, so if 25 million mu have interplanting or continuous cropping of cotton and wheat, 15 million mu have successive crops of green manure and cotton and 10 million mu have successive crops of oil and cotton there will be obvious results in the use and nuturing of the land and in advancing all-round abundance of grains, cotton and oils.

(2) Improvement of the cotton region ecological system and raise the standard of natural energy transfer. Because this cotton region has not developed forestry, animal husbandry, green manure and legumes there is less than 7 percent forest cover, the utilization rate for agricultural resources transformation is very low, there is a decline in the production increases of chemical fertilizers, and the level of materials recycling for nitrogen was only 7-10 jin per mu. From now on, there must be strong improvements in this system's structure and capabilities, there must be energetic afforestation, construction of protective windbreaks for farm fields, implementation of forest and field intercropping, improvement of the farm field microclimate and provision of the "three supplies" (fuel supply, manure supply and fodder supply), and coordinated development of animal husbandry. At the same time, with the day-by-day development of agricultural and industrial production and the daily increasing shortages of water resources there is a need to implement coordinated water storage, irrigation and control of underground water levels and improvement of water use efficiency.

(3) Comprehensive management of low production fields and complete utilization of saline-alkali wasteland. The majority of fields in this region are low or intermediate-yield fields. There are nearly 50 million mu of saline-alkali land, manure and water conditions are poor and comprehensive handling must be exercised. There must be development of well irrigation and well drainage to reduce water salinity. Use of Huangho water for irrigation also requires drainage, and promotion of agricultural techniques for dryland crops will economize on water. Widescale planting of gree manure and legumes will nourish the land and improve the soil.

(4) Cotton field distribution requires a suitable and quick solution for the excessively scattered current arrangement. Most cotton producing counties in this region have less than 100,000 acres of cotton, with a commodity rate of only 88 percent. Within the counties the cotton fields are also extremely scattered, so that it seems as if each individual county, commune and brigade were engaged in cotton growing. From now on there must be emphasis on constructing 80 counties of over 300,000 mu which emphasize cotton production, and there should be reductions of cotton producing counties haveing less than 50,000 mu. There should be rapid and suitable centralization of cotton fields in cotton producing counties.

(5) There must be rapid reform of the current cotton producing technology and the formation of a production technology system having increased production, stable production, superior quality and low waste. First, there must be simplified measures for cotton growing and through comparison of those which do not increase production efficiency or which are only slightly efficient but which use up large amounts of labor and capital must be eliminated. The labor force savings can be expended on cotton field basic construction or on diversification and thus bring about development of cotton field production. Second, the improved varieties must be popularized and the system of breeding the improved varieties should be perfected. These improved varieties must undergo strict regional testing and quality evaluation. There must be a search for a variety of suitable production systems and distribution systems for the improved varieties. Third, there must be firm support of comprehensive prevention of cotton diseases and pests. The process of building an ecologically balanced system for the cotton region must include development of resistant varieties, development of biological prevention and cure, and formulation of high efficiency, low toxicity new pesticides with a suitable period of effectiveness. Fourth, there must be gradual development of mechanized cultivation suitable for the cotton fields of the region, gradual research and formulation of cotton field machinery suitable for the system and special features of cultivation and crop growing in this region, and attention must be given to the suitability of machinery for cultivation techniques. We must do a good job of equipping the presently used farm tools.

(6) Establishment of a Huanghuaihai cotton research center, organization of research on key problems and establishment of a complete technology distribution center. The Huanghuaihai cotton region ought to establish an all-China cotton research center and individual provincial cotton (cash crops) institutes, as well as cotton research organizations in all cotton growing prefectures and counties. There must also be attention to cooperation in the division of labor, avoidance of all unnecessary duplication and waste, improvement of research efficiency and more publication of research results. All levels of agricultural departments and research organizations in the cotton region should establish complete technology distribution organs and form a structured network of technology distribution in order to guarantee the efficient spreading of the results of cotton-related science and technology.

PERFORMANCE REPORT PROVIDED ON NEW HYBRID COTTON VARIETY

Beijing ZHONGGUO NONGMIN BAO in Chinese 30 Sep 82 p 1

/Article: "'Zhongmiansuo No 10" Cotton Much Accepted by Huang and Huai River Area Cotton Farmers; Bumper Yields, Early Maturity, Superior Quality; Continuous Cropping of Wheat and Cotton for Two Crops in A Single Year"/

/Text/ A new cotton variety bred by the Cotton Institute of the Chinese Academy of Agricultural Sciences, "Zhongmiansuo No 10" has shown heartening results in test plantings in cotton growing areas of the Huang, Huai, and Hai river areas during the past several years.

Natural conditions on the Huang-Huai-Hai Plain lend themselves to the growing of cotton and wheat; however, since the frost-free period is faily short, only a single crop a year can be grown on an overwhelming majority of the cultivated land, and wheat and cotton compete rather heavily for the same land. The broad masses of people have hoped for new varieties of early ripening cotton and wheat to permit continuous cropping of wheat and cotton for two crops in a single year and bumper harvests from both.

By way of satisfying the demands of the broad masses of people, beginning in 1975, the Cotton Institute of the Chinese Academy of Agricultural Sciences used "Heishanmian No 1" as its basic material in two breedings, which produced a long fiber, bumper yield, superior variety, natural mutant strain, which was bred to become the early maturing "Zhongmiansuo No 10," which produces bumper yields and fairly good quality fiber cotton. For 3 years in a row from 1979 to 1981, this new variety had a part in regional experiments on varieties suited to a changed farming system in the Huang He basin where it was a frontrunner in both quantity and quality. Last year it was test planted on an area of almost 10,000 mu where wheat and rape had been preceding crops at 22 pilot projects in six provinces including Henen, Hebei, Shandong, Shanxi, Shaanxi, and Jiangsu. It produced yields of about 100 jin per mu where previous crop wheat yields had been 500-600 jin per mu. On the 320,000 mu on which its cultivation has been promoted this year, as of now, in an overwhelming majority of areas, cotton bolls have hung in clusters, growth has been heartening, and a bumper harvest is in prospect. In Linyi County in Shandong Province, where it has been promoted over the widest area, "Zhongmiansuo No 10" was sown in the summer on 100,000 mu. Though it encountered severe drought during the early stages, and though rainfall was concentrated in the middle stages, the cotton still grew better than last year.

Forecasts call for 105 jin per mu of ginned cotton (where the preceding crop had been wheat producing 359 jin per mu). Forecasts also call for the harvest of an additional 35.9 million jin of wheat and increased earnings of 9.8 million yuan as a result of the continuous cropping of both wheat and cotton on these 100,000 mu in the country instead of planting only spring cotton. As a result of the steady increase in the area continuously cropped to wheat and cotton, in many areas both total output of grain and wheat and average per capita distribution have increased rather remarkably. The broad masses of cotton farmers say happily, "A crop of wheat and a crop of cotton; it is white flour we eat; we have money in the bank, and life gets better and better!" In the cotton growing regions of the Huang and the Huai a craze for the growing of "Zhongmiansuo No 10" has taken place, and it is predicted that next year from 5 to 10 million mu of it will be grown.

At a national "Zhongmiansuo No 10" on-site conference held in late September, cotton scientists and technicians from all over the country, leaders concerned, and peasant representatives observed and studied the "Zhongmiansuo No 10" production situation in the four counties of Linyi, Juye, Qufu, and Yanzhou in Shandong Province. They summarized and exchanged experience, explored the impact on the agricultural economic structure of the Huang-Huai-Hai cotton growing regions of this vareity, and the value it should have for China's agricultural production. The conference unanimously agreed that "Zhongmiansuo No 10" is a rather good breakthrough variety that China has bred; that it tolerates waterlogging, tolerates salinity and alkalinity, and is strongly adaptable. In particular, its growing season is about 30 days less than for spring sown cotton in general, and when planted in tandem with correspondingly early maturing wheat varieties and rotationally cropped, two crops a year will be possible on the Huang-Huai-Hai Plain, and this will help solve the competition for land between grain and cotton. Nevertheless, it is prone to fusarium wilt, and it should not be grown in fusarium wilt areas. In promoting it to large area cultivation, all jurisdictions should pay attention to purification and rejuvenation of the variety, and do a good job of seed selection and seed retention work.

NATIONAL COTTON OUTPUT, PROCUREMENT PROSPECTS AT ALL-TIME HIGH

Beijing ZHONGGUO NONGMIN BAO in Chinese 30 Sep 82 p 1

[Article: "More Than 2.5 Million Dan of Ginned Cotton Procured Nationally; Prospects That This Year's Procurement Will Again Reach All-Time High"]

[Text] Ever since the Third Plenary Session of the 11th Party Central Committee, China's cotton production situation has become better year by year. The more than 86 million mu area sown to cotton this year is 8.7 million mu more than last year, and the highest year since the 1960's. During July and August many cotton growing areas had long overcast and rainy periods, and some were even stricken with hailstones and typhoons, which hurt blossoming and boll formation. However, thanks to the steady implementation and perfection of production responsibility systems, cotton farmers actively worked to prevent and combat disasters, thereby reducing losses. If no exceptionally large disasters occur from now on, prospects are that this year's cotton procurement will reach an all-time high. Statistics as of 20 September show more than 2.5 million dan of ginned cotton as having been procured nationally, more than 1.3 million dan in Shandong Province, and 5.4 million dan in Hebei, more than 500,000 more in each case than during the same period last year. Spurred on by the spirit of the 12th Party Central Committee, the broad masses of cadres and people in cotton growing areas eagerly sold more and better cotton to the state following harvesting of a bumper crop. Cotton procurement departments everywhere are now in processing of doing a good job of sales organization work, setting up sales points in designated areas, arranging allocation times, weighing several times amounts taken in, establishing more windows for settling accounts, and such matters to achieve proportional sales by production teams, work teams, and households against vouchers.

SUCCESS REPORTED IN REMOTE HYBRIDIZATION OF NAKED OATS

Beijing GUANGMING RIBAO in Chinese 23 Sep 82 p 1

[Article: "Middle-age Agricultural Researcher Li Chengxiong [2621 2052 7160] Wins Honor for Yanbei People by Breeding China's First Remotely Hybridized New Naked Oats Variety; Yields of 550 Jin Per Mu, About a 10-Fold Increase Over Local Traditional Varieties"]

[Text] Forty-three year old agricultural researcher, Li Chengxiong, has bred China's first remotely hybridized new naked oats variety, multiple spike naked oats. Yields are 550 jin per mu, which is about 10 times that of local conventional varieties. Recently Li Chengxiong has been hailed as a model science and technology worker in Yanbei Prefecture, Shanxi Province.

Li Chengxiong is an assistant researcher in the Frigid Region Crop Institute of the Shanxi Provincial Academy of Agricultural Sciences, and director of its naked oats research office. Following graduation from agricultural technical training school in 1961, he was assigned to this institute to do naked oats breeding work. Oats tolerates infertile soil, is drought resistant, is rich in nutrients, releases large amounts of calories, and contains more fat, protein, calcium, iron, and riboflavin than both husked rice and wheat flour. It is "a treasure" of the people of Yanbei. Yields were only 35 jin per mu, so in order to breed a high yield superior variety of naked oats for the benefit of the people of Yanbei, Li Chengxiong took several years time and visited almost 100 production teams in the naked oats growing region to collect large quantities of breeding materials. It was from peasant varieties that he selected several high yield varieties. In 1964 he began the work of crossing naked oats varieties, but his experiments did not earn the serious attention of leaders, the experiments were very poor, and he had no workers to help him. He had more work than he could do, so he often had his wife and son help. In this way he overcame great difficulties, finally breeding hybrid variety "Yanhong No I-14" in 1979 with yields about double those of old varieties. This won him a second prize for accomplishments from the Shanxi Academy of Agricultural Sciences.

In the early 1970's, Li Chengxiong spotted a mutant plant with dense spikes, numerous pods, and numerous grains from an atomically radiated variety. He analyzed the main reasons for low naked oats yields as being spread out spikes, few pods or grains, and a not high weight per thousand grains. Were he able to breed spikes like those on the mutant, high yields would be possible. In order to get more good mutant plants, he began to collect plants in six provinces and autonomous regions including Hebei, Nei Monggol, Gasu, and Ningxia. The result was collection of only somewhat more than 70 mutant plants of pi [4122] oats. Pi oats and naked oats are of different species, but Li Chengxiong discovered that they had identical numbers of chromosomes and he thought to himself that if successfully hybridized, a high yield variety might be bred. Li Chengxiong thereupon began breeding work on the remote hybridization of naked oats. At first the hybridized plants would not set grain, and later after setting grain, they became mongrelized. After repeated failures, a comrade who was working on the experiments with him lost confidnece. But Li Chengxiong remained steadfast. Since the two set grains following crossing, there was hope. During the season for sowing in 1974, Li Chengxiong had to go to hospital for surgery to remove a large growth on his back. He was afraid he would miss the sowing season, so before his wound had healed he hobbled off on crutches, his back bent, to the experimental ground. This year a distinctive oats plant with dense spikes and numerous pods grew in the experimental ground, and Li Chengxiong was captivated by this oats plant. As expected, he collected more than 180 grains of pure naked oats seeds from this distinctive plant. He was tickled pink and quickly ran to the institute's CPC committee secretary and said, "Distant hybridization has succeeded." Later on this new naked oats variety was experimentally grown in Shanxi, Nei Monggol, and Hebei with results in yields averaging 550 jin per mu with some as high as 675 jin. Cadres and masses said that Li Chengxiong did meritorious service for the people of Yanbei. This year both Yanbei and Xinxian Prefectures have promoted this variety of naked oats to cultivation on more than 100,000 mu where mostly it is growing very well and may produce an all-time high output. Now Li Chengxiong is busy writing pertinent chapters in China's first book on "Chinese Naked Oats."

RURAL ECONOMIES URGED TO BLAZE NEW TRAILS IN ECONOMIC DIVERSIFICATION

Beijing ZHONGGUO NONGMIN BAO in Chinese 23 Sep 82 p 1

[Article by commentator: "Break Through the Old Rigamarole To Study New Problems"]

[Text] Today rural villages have fairly generally established responsibility systems linked to output. After most basic accounting units have instituted "double contracting" [contracting with individual households for task completion and output quotas], in particular, what is to be done in the case of existing collective enterprises? How are the newly emerging associations among the masses to be regarded? This is a new problem about which people are concerned. Comrade Hu Yaobang, in his report to the 12th party Central Committee titled, "The New Situation in All-Around Initiation of Socialist Modern Construction" made an extremely important exposition of this problem. After pointing out the basic principle that "in rural villages, the cooperative economy of collective ownership by the working people is the principal economic form," he particularly stressed that "development of the agricultural economy and improvement in peasant capabilities to administer and manage, will inevitably pose new demands for associated operations of all kinds." We should promote diverse forms of economic association genuinely on the principles of benefits to production and voluntary participation for mutual benefit.

China's agriculture has to take the path of economic diversification. Development of economic diversification requires encouraging the country, collectives, and individual commune members to rise together. This is the correct program and policy formulated by our party so that the 800 million peasants will become prosperous with all possible speed. China's commune and brigade enterprises are a force that is not to be ignored. Today they hold more than 50 billion yuan of property, employ more than 30 million people engaged part time in industry and part time in farming, and have an annual output value of more than 70 billion yuan. They play a very important role in the employment of surplus workforces, in enlivening the rural economy, in assisting national construction, and in increasing peasant income. In the process of their development, commune and brigade enterprises experienced problems in rash action, blind building of plants, poor management, and not very high benefits. Through future reorganization, these problems can be solved for healthy development of the enterprises. Development of rural collective enterprises has also been fettered by some old rigamarole. Formerly many people believed that only communes and brigades could run enterprises and that production teams could not do so, much less commune members.

However, since the 3d Plenum of the 11th Party Central Committee, changes in the rural situation have broken through this old rigamarole. Facts have shown that not all communes and brigades necessarily have conditions requisite to the running of enterprises, and that enterprises do not necessarily have to be run by communes or brigades. To meet the needs of the development of production, specialized households, multiple occupation households, and all kinds of new economically associated groups have gradually begun to grow. Collective enterprises operated by persons adept at administration and possessed of skills in conjunction with workers can equally play a positive role in development of production. We should thoroughly investigate and study these new associated enterprises, diligently summarize their experiences, and help their healthy development genuinely in accordance with the principles of advantages for production and voluntary participation and mutual benefit. Structure of a socialist agricultural economy has to be diverse. Only in this way can more rapid development of socialist productivity be advanced so that the superiority of the socialist system is brought into full play. While actively fostering commune member household sideline occupations, we should strive to operate various kinds of cooperative enterpries collectively owned by rural working people.

A look at the development of rural economic diversification shows that in the development of these enterprises it is necessary to take into consideration local skills, the economy, transportation, markets, and such conditions, and to consider in combination the problems of supply, production, and marketing. Just what provisions are made will depend on local realities. Conditions vary from place to place, and many types of enterprises may come into being. In areas close to large cities or near certain developed areas, conditions exist for the operation of some labor-intensive industrial enterprise to serve large industry. In most places, however, economic diversification will consist of farming, livestock raising, or processing. Right now some circumstances merit attention, such as the following: Everywhere today households specializing in the raising of livestock need others to help them solve problems in producing young animals, livestock feeds, technical guidance, and marketing of products. Once products of the livestock breeding industry have become more numerous, some will require local processing and storage followed by continuous marketing elsewhere. If some products cannot be sold, it may not be for lack of demand, but because they cannot be transported elsewhere. To solve these problems, the state will have to make plans and collectives will have to get to work. Operation of some young animal farms, livestock feed processing plants, farm product processing plants, technical service stations, marketing outlets and storage and transportation departments under guidance of state economic plans and through the use of collective strength fits in with needs. Where existing commune and brigade forces cannot solve the problems, commune members may organize to pool funds to conduct activities. When a single unit or a single place cannot solve the problems, it may associate with other units or other places in joint efforts toward solutions. Where grassroots cannot solve the problems, leadership organizations above the county level should organize the necessary cooperation. Pilot projects may be used to solve these kinds of problems, to gain experiences, to work out a rational structure, and to move economic diversification gradually toward specialization and socialization.

Breaking through old rigamaroles to study new problems, use of pilot projects to gain experiences, and making collective enterprise avenues ever wider so that the rural economy will become ever more lively are major problems in continued development of the very fine rural situation.

CHANGES IN CHRONICALLY DEPRESSED COUNTY ECONOMIES REPORTED

Beijing RENMIN RIBAO in Chinese 16 Oct 82 p 2

[Article: "Appearance of a New Outlook Caused by Initial Tapping of Potentials--Notes on the Changes in the Ten Chronically Backward Counties in Anhui Province--On All-Out Efforts to Develop a Diversified Economy, Spurred by Party Policies"]

[Text] In terms of time, 3 years is only one-tenth of 30 years, but in the n0 notorious chronically backward counties of Anhui Province, increase in production figures for the 3 year period from 1979 to 1981 was greater than for the 30 year period from 1949 to 1978. Statistics show a 1981 increase in grain output of 2.239 billion jin over 1978, and an increase of only 1.317 billion in the grain output in 1978 over 1949; a 300 million jin increase in oil bearing crops in 1981 as compared with 1978, and only a 36 million jin increase in oil bearing crops in 1978 as compared with 1949. Average per capita increase in income for 1978 was about 40 yuan greater than in 1949, while the increase was 152.40 yuan in 1981 as compared with 1978.

The 10 counties in this chronically poverty stricken area are Si County, and Wuhe, Lingbi, Guzhen, Dingyuan, Fengyang, Jiashan, Xuancheng, Langqi, and Guangde counties. They are located on the Huaibei Plain, the hill region of the Chang Jiang and Huai Jiang, and in the mountain region of southern Anhui. They contain a 5.55 million population and 10.89 million mu of cultivated land. Since the Third Plenary Session of the 11th Party Central Committee, these 10 poor counties have made great strides in catching up, and half of them have vaulted into the ranks of the province's advanced counties.

Heartening Reports from "Beggar Villages"

In May this year, Anhui Provincial CPC Committee secretary, Wang Guangyu [3769 0342 1342] received a letter from a Huaibei rgral village. On opening it he found that it contained a heartening report mailed by commune member Chen Yuzhi [3769 3768 5347] at Huangzhuang Proeuction Team, Huangzhuang Production Brigade, Maoqiao Commune, in Guzhen County. It reported three heartening situations to him. First was the harvest last year of 10,000 jin of grain for economic income of 5,000 yuan. Second was the building of four new tile-roof houses. Third was that her three sons had become engaged to be married. Chen Yuzhi had owned the house in which Wong had stayed 15 years previously when he had been sent down to the countryside to toil, and it had been in her house that he had eaten and lived. At that time Xiaohuangzhuang had been a "poverty-stricken beggar village" where no one ate wheat flour or rice or lived in a tile-roof house. Now upon learning that sguch great changes had taken place for Chen Yuzhi's family, he was really excited.

On 14 August on this way back from attending the Seventh Plenary Session in Beijing, before arriving at Hefei, he got off the train in Guzhen specifically for the purpose of going to Xiaohuangzhuang to visit the country relatives he had not seen for many years. No sooner had he entered the village when commune member Chen Yuzhi, her faced wreathed in smiles, welcomed him to her home. Chen Yuzhi said, "Today is greatly different than 15 years ago! It would have been impossible then forme to have given you a steamed white bread. But now everybody has white steamed bread to eat, and every household has grain on hand. My family has the equivalent of more than 1,000 jin of wheat per person this year, and not only will we be unable to eat that much, but we worry about not being able to sell it!" The production brigade secretary also interjected, "These 3 years have brought rice and wheat flour to eat, the building of tile-roof houses, and each year has been better than the previous one! We used to lack food, not have enough to wear, and go begging, but now every family makes a contribution. Last year this production team contributed more than 30,000 jin of grain to the state. For wheat alone, each person sold an average of 250 jin, more grain than they had harvested 3 years earlier!"

The changes that had taken placed in Xiaohuangzhuang were a microcosm of the changes that had taken place in countless "beggar villages" in the 10 poor counties. Guxhen County, in which this village was located, had been the poorest of all the 10 poor counties. In the 13 years between the establishment of the county in 1965 and 1978, its people had eaten a total of 124 million jin of grain sold back to them by the state, and many peasants had been unable for a long time to break out of their poverty stricken situation of "planting in spring, harvesting in fall, and fleeing from famine in winter, sweet potatoes being their staple food." During the past 3 years, not only has the problem of sufficient warm clothers to wear and food to eat for the masses been solved, but with a single leap the county has gone from being the one that ate the most grain sold back to it by the state to an advanced one that made an annual contribution of 174 million jin of grain to the state, each person init providing more than 600 jin of commodity grain. A 60-year old commune member named Ou Mingxian [0575 2494 6513], who everyone calls "Old Grouch," lives in Ouxi Production Team in Aingliang Production Brigade, Qingliang Commune. After institution of "large scale contracting of full responsibility for completion of work tasks," the party's policies made him a little more open-minded and widened his thinking horizons. Last year his family of four sold the state 15,000 jin of grain, 7,000 jin of which was wheat. This summer his family harvested 14,000 jin of wheat, and he sold the state 10,000 jin in a single season.

"Airport" Removal

Pronounced characteristics of the 10 poor counties are small population relative to available land and great potential. Three years ago when the correspondent passed through Dingyuan, Fengyang, and Jiashan counties, it was possible to see large flat areas of wasteland at any time where no crops but only weeds grew. In some places there was more than 1,000 mu of such land extending far off into the distance like the broad runways on which aircraft take off and land. Consequently, the local people called this stretch of wasteland "the airport."

Today, one after another, high yield models have taken off from this "airport," and no longer does a barren vista loom before one, but rather a boundless tract of golden paddy rice, and glossy green peanut, soybean, and sesame crops. A comrade in charge at the Dingyuan County CPC Committee told the correspondent that the county use to have 200,000 mu of big and small "airports," that had turned into "granaries" during the past 2 years, providing more than 80 million jin of commodity grain and oil-bearing crops to the state annually and creating considerable wealth. As peasant levels of scientific farming increase, the potential of the "airfields" has become greater!

"From a burden to wealth has been the result of 'contracting'". With no campaigns that shake up people, elimination of "eating out of a large common pot," institution of large scale contracting of full responsibility for completion of work tasks, county CPC committee diligent implementation of specific regulations pertaining to unworked wastelands, "four-besides land" (beside homes, beside roads, beside rivers, and beside mountains) with ownership going to whomever develops them, and those who do the planting getting the harvest, suddenly commune member enthusiasm for production has been aroused.

In the course of our visit to Dingyuan County's rural villages, we heard numerous moving stories about the development of the "airports." At Xiapang Production Team in Gengxiang Production Brigade, Gengxiang Commune, the heads of 11 households served as production team leaders, which meant they were unable to give full attention to their fields and yields declined, leaving behind an "airport" each year. In many years yields from then were only about 100 jin per mu and wheat rations did not amount to much. Up until 1978 total annual grain output was no more than 30,000 jin. In 1979, old brigade leader Liu Jiasheng [0491 1367 0524], who had been forced to step down on several occasions, resumed his responsibility for the entire production team, instituted the contracting of output to individual households, and rallied everyone to march on the "airports." Quite a few commune members were apprehensive and were slow to act. He thereupon both publicized the party's policies and took the lead in being an example. He led his family of seven in farming the land for which it had contracted while at the same time reclaiming for cultivation 15 mu of wasteland, which they planted to fennel, sweet potatoes, paddy rice, and soybeans. At his urging commune members in the production team opened to cultivation more than 200 mu of "airports" within 3 years, harvesting more than 60,000 jin of grain from these lands alone. This was twice the brigade's total grain output in 1978.

Commune members said, "the land has changed much; the soil has become more fertile; people work harder, so how could there by anything but increase in production!" Last year the brigade's grain output vaulted from the 30,000 jin of 1978 to 183,000 jin, an output averaging 16,600 jin per household. Economic diversification also advanced very rapidly with annual per capita net income increasing from somewhat more than 50 yuan 3 years previously to somewhat more than 500 yuan. The masses happily sang, "Xiapang, Xiapang, where granaries are full of grain and ponds full of fish, where people have new clothes to wear and new houses to live in."

There were more places in Dingyuan County like Xiapang. In 3 years agriculture throughout the county made three giant strides. Grain output increased by 100 million jin in a year, output going from 440 million jin in 1978 to 750 million jin, and gross output of oil-bearing crops shot up from somewhat more than 20 million jin to somewhat more than 80 million jin for a manifold increase in contributions to the country. In 1980 the county used "households with an output of 10,000 jin of grain" as the standard for selection of "outstanding households" that had become wealthy through labor, but in 1981 the criterion for participation in the countrywide "outstanding household" conference was changed to "households who had sold 10,000 jin of grain." This change was made because in that year the number of households that produced 10,000 jin of grain shot up from the somewhat more than 300 of the previous year to more than 10,000!

In the other nine poor counties, the situation was very much the same. In 1979, "10,000 jin of grain households" were scarcer than hens teeth in these 10 counties, but by last year there wer more than 10,000 of them!

More to be Done About "More"

Following the Third Plenary Session of the 11th Party Central Committee, "leftist" influence was swept away and people in mountain regions removed their shackles. County CPC committees in Xuan, Lang, and Guang counties in the mountain region of southern Anhui Province shifted the focus of work in the mountain region from the former sole emphasis on grain to development of forestry and economic diversification. As a result, the mountain region gradually began to come alive.

Xuancheng County proceeded from realities in an adaptation of general methods to the local situation to built 10 economic diversification bases for forestry and tea, honey dates, tung oil trees, silkworm mulberry, Chinese herbal medicines, fish raising, etc. In addition it gave energetic encouragement to commune members to use the space in front of and beyond their houses as well as privately retained mountains and private plots to develop the "10 smalls," i.e., small wooded groves, small orchards, small tea farms, small mulberry groves, small fish ponds, small plant nurseries, small tung oil groves, small plaiting plants, and small livestock farms. Xiting Production Brigade in Yingliu Commune in this county used the "four besides" to develop small woodlands where it planted 150,000 trees of various kinds, or an average of somewhat more than 1,100 trees per household. In Langqi County, the number of households specializing in various aspects of the breeding industry alone have grown to more than 8,900, or 16.5 percent of the total number of peasant households in the county. In Yejia Production Team in Daji Production Brigade, Dongxia Commune, duck raising hand, Ye Shengxu [0673 3932 1331] who was criticized for raising ducks 10 years ago, last year raised 170 ducks in sheds with the encouragement and support of leaders at all levels, and sold 3,400 jin of duck eggs to the state for a net income of more than 3,800 yuan to become a famous household in the county that prospered by working. On two occasions, he had the honor attending county and provincial meetings of delegates advanced in economic diversification.

Party policies have been like a golden key that has opened the main door to prosperity in mountain regions. Sihe Commune in Guangde County is a prominent example. Three years ago this commune was still fairly poor. Since 1979, however, the commune CPC committee shifted the focus from sole attention to farmlands to mountains where it began afforestration in vigorous development of economic diversification. Within the period of 3 years, the commune afforested 50,000 mu of barren mountains, planted more than 1,600 mu of economic forests of silkworm mulberry, chestnut, and tung oil trees, more than 500,000 lacquer trees, and more than 4,000 mu of round bamboo. Last year the commune produced 6,000 dan of chestnuts, selling 5,500 dan or half the amount purchased from the county, to the state, becoming famed as a "land of chestnuts." In 1179 and in 1981, this commune used its advantages in having large numbers of silkworm cocoons nd a large workforce to build a textile plant and a filature mill, making the raising of silkworms, the reeling of silk, and weaving of cloth a continuous process. Since last year the textile plant has produced 200,000 soft solk quilt covers in satin weave, which are enjoying sales in Tianjin, Shanghai, and elsewhere. In addition, in the past 3 years it has used local resources to run a food products plant, a large tile plant, a lace industrial arts plant, and a fluorspar mine as part of 20 commune operated enterprises. It has started construction of a reservoir with a water storage capacity of nearly 4 million cubic meters, and has built 20 small hydropower stations so that almost one-half of the commune's wetlands are unaffected by waterlogging or drought, and more than 60 percent of production teams and commune members have electricity. Last year the commune's gross income from economic diversification amounted to 4.75 million yuan, three times that of 1978. Income from economic diversification as a proportion of gross income from agriculture rose from 30 percent to 70 percent, and commune member average per capita income increased from 100 yuan to 311 yuan. Now Sihe Commune has become a thriving new socialist mountain village where the mountains are green and the water clear. It has blazed a new trail toward prosperity for the mountain regions of southern Anhui.

Heartening changes have taken place during the past 3 years in the appearance of the mountain region in Xuancheng, Langqi, and Guangde counties where farming, forestry, livestock raising, sideline occupations, and fisheries mutually support each other for a fine situation of comprehensive development. Comparison of last year with 1978 shows total grain output in the three counties to have increased 30 percent, and income from economic diversification to have more than doubled, total earnings from economic diversification as a proportion of total earnings from agriculture having risen from 40 to 54 percent, and average per capita commune member earnings having increased from 105 yuan to more than 240 yuan.

Now, the people of these 10 counties, given encouragement by the 12th Party Central Committee, are writing a new chapter in the building of new rural villages and becoming prosperous through labor.

PROBLEMS, PROSPECTS IN RURAL PREFECTURE IN ANHUI SCRUTINIZED

Beijing ZHONGGUO SHEHUI KEXUE [SOCIAL SCIENCE IN CHINA] in Chinese No 3, 1982 pp 73-110

[Article by Chinese Rural Development Problem Study Team: "Several New Problems in Rural Development--A Survey of Rural Villages in Chuxian Prefecture, Anhui Province Following 'Double Contracting to Households'"]

[Text] Editor's Note: This article is a survey report on rural villages in Chuxian Prefecture, Anhui Province. This survey report makes clear that establishment of production responsibility systems of "double contracts" with households [contracting for fixed output quotas from households and contracting responsibility for full task completion with households], stirred peasant enthusiasm for production to an extreme extent, but also posed numerous new problems requiring solution.

This article emphasizes exploration of several problems including grain production, land contracting, the gap between poverty and riches, the direction of flow of workforces and funds, new cooperative associations, the functional structure of the rural economy, and rural grassroots cadres. The author believes that study of these new problems and new trends in rural development hold major theoretical and practical significance for understanding the orientation of rural economic development, and for further development of a very fine rural situation so that reform of the rural economic system will be carried out in a healthy way.

The author of this survey report, the Chinese Rural Development Problem Study Team, is a sparetime academic study organization composed of a few score young theoretical workers, research fellows and university students who work under the guidance of the Agricultural Economy Research Institute of the Chinese Academy of Social Sciences.

China's farflung rural villages are currently undergoing a thorough economic restructuring. The unprecedently high enthusiasm for production of hundreds of millions of peasants is a major mark of the success that this restructuring has achieved. Establishment of various forms of production responsibility systems makes a fine starting point for this restructuring. The economic accounting units in rural villages throughout the country that have already set up various forms of a production responsibility system number 97.8 percent of all economic accounting units, and those practicing "double contracting to households" (contracting production to households and contracting work tasks to households) is close to 50 percent. Establishment of production responsibility systems far exceed their original significance; they are, in fact, a partial readjustment of production relationships. Thus, study of the new problems and new trends following institution of various forms of responsibility systems, and particularly following institution of double contracting to households, holds major significance for further development of the very fine rural situation and for promoting the smooth socio-economic restructuring of rural villages.

In this connection, we conducted a survey in Chuxian Prefecture, Anhui Province during July and August 1981. This survey centered around "the new problems and new trends that had appeared in rural development following double contracting to households." In Chuxian Prefecture rural villages instituted various forms of responsibility systems at a fairly early time, and now double contracting to households is done in more than 97 percent of all households. This prefecture is located in the hills between the Yangtze and Huai rivers where natural conditions are moderately good. Prior to 1977 the prefecture was below average national levels in terms of average agricultural output value for the rural population, as well as in terms of grain output and commodity rate. During the last 2 years it has greatly exceeded the average national levels.

The main focus of our survey was on the following several problems:

I. Grain Output Problems

It is common knowledge that no great change in the diet of the Chinese people is possible within a short period of time, and that for a fairly long period of time both agricultural production and food consumption must be chiefly in the form of grain. The outlook for grain production has a great bearing on growth of China's national economy. What is the situation in grain production in areas where double contracting to households has been done, and what is the trend of development? The Chuxian Prefecture survey helped enlighten us.

1. The Shortterm Trend in Grain Production

Chuxian Prefecture has 6.5 million mu of cultivated land (actually more than this figure). In 1976 and 1977 it produced 2.8 billion jin of grain annually.

As a result of severe natural disasters in 1978, this figure fell to 2.3 billion jin. In 1979, despite disasters one after another, as a result of the initiation of the contracting of production to teams, it again rose to 2.8 billion jin. In 1980, by which time half of all production teams had instituted double contracting to households, grain output totaled 3.2 billion jin for a net increase of 400 million jin. In 1981, when more than 90 percent of production teams were practicing double contracting to households, grain output totaled 4 billion jin, a net increase of 800 million jin. Within the very short space of 2 years, a greater than 40 percent increase occurred with unprecedented rapidity.

The most fundamental reason for this increase was the liberalization of rural economic policies and institution of responsibility systems of double contracting to households that followed in the wake of the Third Plenary Session of the 11th Party Central Committee and aroused extreme peasant enthusiasm for production. Specific reasons were: First, expansion of the cultivated area and increase in the land's extensive utilization rate. Abandoned and waste lands were brought under cultivation for an increase in the grainfield area. Second, intensive farming for an increase in yields per unit of area. This was an increase in input of labor, improvement in field care, greatly increased use of chemical fertilizers (the prefecture using in 1981 double the amount of 1979), further promotion of superior crop varieties, increase in the multiple cropping index, etc.

2. Shortterm Forecast for Grain Output

Following the double contracting to households, grain production expanded very rapidly, but will it be possible in future years to continue this fairly rapid speed of growth? This is a problem that concerns everybody. According to estimates made by comrades in the policy research offices of the Fengyang and Dingyuan County CPC committees, in normal years grain output can continue to increase for from 3 to 5 years at a 5 to 7 percent rate of speed. The principal bases for the sustained fairly rapid growth in grain output for the past several years have been the following:

(1) More sensible input of labor and further improvement in field care; (2) continued increase in the amount of barnyard manure used for improvement in the soil's physical structure and an increase in its fertility; (3) increase in quantities of chemical fertilizer used; (4) further promotion of superior varieties; and (5) increase in high yield dryland crops. In short, the increases in grain output over the next several years will depend to a fairly large extent on increases in yields per unit of area. Today, grain yields in Chuxian Prefecture as figured on the basis of area sown amount to only 300 jin per mu. Within several years, fairly substantial increases in yields per unit of area are entirely possible.

However, after 1985 unless appreciable improvements are made in agricultural production conditions and the farming system, the speed of increase in grain production will slacken and become low-speed growth. The main foundation for this contention is as follows: (1) difficulties in further increasing either the cultivated land area or the area sown to grain. To bring virgin soil under cultivation will mean intensification of erosion and destruction of the ecological balance, the losses outweighing the gains; (2) difficulties in continuing to increase the multiple cropping index; (3) difficulties in continuing tremendous increases in chemical fertilizer supply; (4) difficulties in further improving water conservancy conditions within a short period of time; and (5) because of insufficient fertilizer, the soil is asked to produce more than it can. In summary, unless existing production conditions meet requirements for continued growth of production and are substantially improved, the speed of growth of grain production will be very limited.

This shows that as a result of increase in peasant enthusiasm following institution of double contracting to households, sustained increase in grain production over a period of 3 to 5 years is possible. However, unless attention is given improvement of existing production conditions and new farming programs adopted, such as banding together for farmland capital construction and creating a new type farming system suited to the scale of operations, it will be impossible to continue to maintain the present growth impetus and the speed of development must inevitably slacken. A country as large as China must commit itself to solution of its own grain problems and "positively no slackening in grain production" must become our basic national policy. The problem is that in some future years, conditions that limit growth of grain output will become increasingly numerous, and potential for use of existing production conditions will become increasingly less. We should begin now to study prospects for grain production and take the necessary action for sustained growth of both grain production and other economic diversification as well.

II. Problems in Farming the Land

Land is the basic element that limits agricultural development. A fundamental characteristic of double contracting to households is dispersal of collectively owned land to peasant households for farming under contract. Peasant enthusiasm for farming the land has been aroused. Formerly rectangular plots were farmed as gardens, but now gardens are farmed as rectangular plots once again. Borders and corners of fields, and areas in front of and behind houses are used, small size farmland water conservancy facilities within the area farmed by peasant households have also been rapidly put in operating condition. Peasant households have self-determination; they may plan their crop rotation rationally on the basis of soil fertility and market demand under guidance of state plans. Both land utilization rates and results from farming have generally increased. All this makes for very great progress over the former method of a "great hullabaloo." However, this does not mean that all the problems in peasant household contracting the farming of public land have been solved. As a result of the Chuxian Prefecture survey, we feel that the following several problems exist in farming of the land that are related to double contracting to households.

1. Land Contracting Problems

Land can be good or bad, distant or near, wet or dry, flat or hilly, and differences in water supply situations may also exist. In contracting land, a method of matching up to make an average is mostly done, and this causes substantial fragmenting of the contracted land. Not only does this fragmenting make for inconvenience in peasant field operations and care, but even more importantly it plays hobs with the water system. Crop varieties and rotation of crops differ from one household to another, and both amounts of water used and times of use vary, conflicts in the use of water frequently resulting. In Chuxian Prefecture, wetlands account for 58 percent of the cultivated land area. During the past 2 years there have been no very large disasters in the prefecture, but between 20 and 30 percent of all civil incidents have related directly to arguments about use of water. Were there to be a serious drought, there would be even more conflicts.

Not only this, but because the population is large relative to available land, in most communes and brigades the land was proportionally contracted according to population, or according to population and the workforce. However, the size of the population and workforce frequently changed. In our survey of 2,079 households in four communes in two counties, in the space of 2 years population changes took place in 325 households for a change rate of 15.6 percent. Of these, the change rate was 10 percent in the contracting of land on the basis of population. Where land had been contracted in proportion to both population and workforces, the change rate was about 20 percent. During the past 2 years increase or decrease in population occurred in 12 of the 34 households in the Guojia Small Team of Jiangshan Production Brigade in Jiangshan Commune in Fengyang County. This was 35 percent of the total number of peasant households. In 10 of the 25 households in the Xiaowang Production Team of Qianjin Production Brigade in that same commune, population increases or decreases occurred. That was in 40 percent of all households. In Daqihe Commune in Fengyang County, in 12 of the peasant households that held certificates showing birth of only a single son or daughter, none of the sons or daughters were contracted land. In some cases where young men had married and born a child, one-tenth of a mu of land was contracted for all three. In places practicing double contracting to households, land in an overwhelming majority of communes and brigades has already been completely contracted and it has been expressly provided in writing that no changes are to take place for several years. As time passes, changes in both population and workforces will continue to occur. Thus, the issue of readjustment of land contracting must be put on the agenda.

On the question of land problems requiring readjustment such as fragmentation of land for contracting, playing hobs with the water system, and population changes, Chuxian Prefecture already has fairly good experience. Beginning in 1980, Songshushan Small Team in Sansheng Commune, Quanjiao County evaluated output of each and every natural plot of land, finding maximum yield of 700 jin per mu and a minimum yield of 400 jin per mu. It followed this with an assessment of 3.50 yuan for every 100 jin of evaluated yield to be payed as a state purchase quota and collective withholdings, which was also prorated for plots of different quality, more being assessed for use of good land, and less being assessed for poor fields to balance out differential incomes from different quality plots contracted for. The brigade also carried out a pond by pond evaluation of large and small ponds in terms of their different water storage capacities, large ponds to be used in common and those using small ponds to get supplementary amounts of water from the brigade according to a unified system, thereby solving problems arising out of different water conditions. Proceeding on the basis of evaluation of yields for fields and evaluation of water in ponds, the brigade layed out new continuous strips of land on the basis of different water systems serving them to replace the system whereby land that had been divided into pieces following contracting, thus helping farming. Following such readjustments, commune members were relatively satisfied. During the year preceding this readjustment of land there had been 10 civil quarrels resulting from water use, but following readjustment, there were none. Furthermore, water conservation facilities were put under the care of specific people with commune members taking the initiative in maintaining them in good repair to change the former system of "swarming to use water, but not moving to repair the ponds."

When Xiaowangzhuang Production Team in Jiangshan Commune, Fengyang County instituted contracting of production to individual households in 1979, it held 20 mu of fields in reserve. Should anyone leave the production team as a result of marriage or death, they had to surrender their land and the land became a reserve under centralized control of the production team. Reserve fields were ordinarily contracted out to peasant households with large numbers of workers. When the production team's population increased, an average 2 mu per person of reserve fields was contracted out. In view of the production team's anticipated population increase under its birth control plans, this method will be able to satisfy demands for land resulting from population increase for up to 10 years.

2. Land Utilization Problems

Following double contracting to individual households, the peasants generally planted crops on their land that brought high profits and quick results. They adopted some measures to increase results that were effective at once and did not take the initiative to farm crops requiring several years before benefits could be reaped. They were unwilling to use measures for increasing output that brought longterm benefits. In 1976 Chuxian Prefecture grew 1.31 million mu of green manure, but in 1980 it grew only 300,000 mu. During this same period, quantity of chemical fertilizer applied increased from 87,600 tons to 239,800 tons. Existing wastelands were quickly cleared, and land made by filling in lakes was all planted. In this situation, how to insure that the land's fertility would not decrease with each passing year, and how to carry out a rational reversion of cultivated land to forests or fisheries to maintain the ecological balance, and such longterm measures, was a difficult problem urgently in need of study and solution.

After their longrange use and rights to farm the land, as well as their rights to farm the land as they wanted changed, the peasant's did some longrange thinking about farming the land and realized this was closely related to investment in the land. Readjustment of the land would make peasant investment in the land for which they contracted change as their rights to farm the land changed. Action to achieve ecological balance, and use of cultivated land for the building of water conservancy and other public facilities would hurt the peasants' direct interests. Under these circumstances, were the method of egalitarianism and indiscriminate transfer of resources to be applied simplistically in readjustment of the land and to solve problems in use of land for public facilities, that would either meet with peasant opposition or result in the land being farmed in a plundering fashion. It was necessary to let the peasants make longterm plans and encourage the peasants to undertake large scale, longterm investments to improve land quality. Suitable methods had to be adopted so that peasants would be compensated for the living labor and the embodied labor that they invested in improving the land. It was necessary, in addition, to induce the peasants to consider their longrange interests by growing crops that nurtured the soil and by rational crop rotation. This required corresponding economic measures as inducements.

3. Problems in Land Transfers

In order to fully guarantee public ownership of land, areas instituting double contracting to individual households framed regulations not allowing the transfer, rental, or sale of land, and not permitting the hiring of workers to farm it. They also took action to render assistance to hardship households. Under these circumstances instances of land transfers or hiring of workers were few and far between in Chuxian Prefecture. Comrades in the Fengyang County Policy Research Office reported that an overwhelming majority of peasant households contracting land were able to farm it themselves, but for about 2 to 3 percent of peasant households farming was difficult. The main workforce in some of these was either cadres or industrial workers; some were engaged in industrial sideline occupations and business, and some were hardship households with no able-bodied workers. How could such peasant households solve difficulties in independent farming? (1) An overwhelming majority did the work themselves, asking for help during the busy season in farming; (2) In a small number of cases, they farmed a portion of the land themselves and transferred the other part to others to work, the contracting household bearing responsibility for state procurement quotas and withholding quotas for all the contracted land. Alternatively the contracted land was farmed by someone else, the contracting household buying its grain rations at list prices and benefiting from price differences. (3) In extremely few instances, others were asked to do the planting with the harvest reverting to the contracting household and only a portion of the grain being given as compensation to the household doing the farming. Though most of the foregoing three kinds of situations took place among relatives; nevertheless, they were fairly clearly in the nature of hiring workers.

III. Problems of Gaps Between Poverty and Wealth.

Following double contracting to individual households, agricultural production efficiency increased remarkably, but how to avoid a gap between the poor and the rich became an important question about which everyone was concerned. Our understanding of this question is as follows:

1. Extent of Peasant Household Prosperity and Differences

Following double contracting to individual households, peasant income in Chuxian Prefecture increased everywhere. Computation of earnings in terms comparable to the former portion of earnings from collective distributions showed that a commune member income of 79 yuan in 1977 increased to 103 yuan in 1980, a 30.4 percent increase (figured in terms of variable prices, the 1980 amount was 128 yuan, a 62 percent increase). If the portion of earnings derived from commune member household sideline occupations and private plots were added to this, average net income for commune members in the prefecture as a whole was about 200 yuan, an almost doubling of income. We surveyed the family livelihood of 114 peasant households. In only one such household had income declined from what it had been before double contracting to individual households. Prefecture and county policy research office comrades reported that for more than 95 percent of peasant households, earnings had increased considerably.

Comparison of differences in levels of peasant household income today with those before double contracting to individual households was instituted revealed no clear widening trend. Taking three production teams in the prefecture with high, medium, and low income levels as an example (See Table 1), the gap in income between the household with the highest income and the one with the lowest income has narrowed from what it had been before double contracting to individual households. A look at peasant household income levels shows that in Xiaogang and Luzhuang production teams, income levels for each peasant household were closer to the average income level for the team as a whole than was the case before double contracting to individual households. That there has been no clear widening of the gap between the poor and the rich results from the following reasons: Universally high enthusiasm for production; land was proportionally distributed on the basis of population, or on the basis of population and workforces, and not solely on the basis of workforces. In production, individual peasant household could act on their own initiative to make the most of strengths and avoid weaknesses; supplementary workforces in families could be used to full advantage, etc.

2. Peasants' Psychological Reaction to the Gap Between the Poor and the Rich

At the present time the reaction of Chuxian Prefecture peasants to the gap between the poor and the rich is not great, and much less does it pose a threat to social stability and development. The following are the reasons why:

First, peasant income has risen everywhere. Among those we surveyed, the answer from 98.6 percent was "incomes have gone up; at least everyone has food to eat. Those replying, "poor families have also increased their income; they have no cause for complaint," numbered 97.9 percent. This is a solid basis for guaranteeing unruffled peasant feelings and continuation of enthusiasm for production at a high level. For many years they have been frightfully poor, so their first concerns are food to eat and clothes to wear, and during the past 2 years everywhere they have had both. As a result, they are satisfied and are not upset at the existence of a gap between rich and poor.

Second there is no obvious expansion of the gap between the rich and the poor (See Table 1)

Third, everybody now has an opportunity to get rich. Of those surveyed, 88.2 percent replied as follows: "Both the land and the oxen to farm it have been contracted, so those with ability get rich first. No complaints." The peasants now feel that everybody now depends on his own ability and sweat, and works under generally equal production conditions. Amount of earnings depends substantially on amount of work and quality of work and not on social position or special privileges. As far as differences between one household and another in amounts of funds, and amount and quality of able-bodied workers are concerned in these circumstances, most of the peasants felt this was natural and fair.

Fourth, peasant feelings of security have increased. In places like Chuxian Prefecture, the peasants' greatest feeling of insecurity is about not having enough warm clothing to wear or enough food to eat. Double contracting to individual households very quickly solved the peasants' problems with clothing and food: consequently, at the minimum level of human needs, the peasants' feelings of security have been strengthened. In addition, the general increase in commune member income and improvement in relations between one person and another have increased possibilities for mutual cooperation among peasants in money and labor. This has further enhanced their sense of security.

Table 1. Average Income In Representative in Upper, Medium and Low Income Production Teams

Team Name	Year	Average Net Per Capita Income					Average Variation in Average Per Capita Net Income			
		Highest Household	Lowest Household	Difference Between Highest and Lowest Household	Team Average		Original Value	Converted Value	Increase As Compared with Prior to Contracting Individual Households	
		(Yuan)	(Yuan)	(Yuan)	(%)	(Yuan)	(Yuan)	(Yuan)	(Yuan)	(Percent)
Xiaogang	1977	88	6.4	81.6	1275	35	17	168	-	-
	1980	668	168	500	298	342	110	110	-58	-345
Hezhuang	1978	192	36	156	433	116	40	186	-	-
	1980	1146	336	810	241	545	249	249	63	331
Luzhuang	1980	413	117	296	253	198	58	102	-	-
	1981	586	263	323	123	353	61	61	-41	-402

Notes: 1. Luzhuang Team's 1981 income figures have been estimated

2. Because the average value of income for the team as a whole differed before and after contracting work tasks to individual households making comparison of average variation impossible, conversion of the average variation was done on the basis of corresponding proportions, so comparison could be made.

3. Necessity and Practicability of Assisting Hardship Households

Following double contracting to individual households in Chuzian Prefecture, the income of most hardship households increased, and the number of hardship households declined. Take Fuxing Commune in Laian County, for example. There the proportion of hardship households having an annual grain ration of less than 360 jin and average per capita earnings of less than 50 yuan fell from 30 percent of the total number of households in 1977 to 4.5 percent in 1980. Most of the former hardship households got out of their situation of not having enough clothes to keep warm or enough food to eat, and most of the present hardship households have also increased their incomes. Nevertheless, some hardship households have a very hard life, and income has fallen for a very small number of hardship households. An overwhelming majority of them welcomed double contracting to individual households, but their psychological reaction to the gap between poor and rich is stronger than in the case of other peasant households.

A look at the trend of development of the gap between poor and rich shows that unless appropriate action is taken, any one of the following situations can occur: As problems of having sufficient warm clothing to wear and enough food to eat are universally solved and contracting to individual households goes on for a long period of time, the peasants will become increasingly concerned about the gap between rich and poor. Prosperous households will use the abundant funds and the fairly high production technology they have at hand to either directly or indirectly transgress the interests of hardship households. Equality of opportunity to become rich will be destroyed, and hardship households will transfer possession of their production tools or even covertly transfer land. In this way the gap between the rich and the poor will exhibit a tendency to widen becoming an element in the destruction of social order and development. For these reasons, assistance to hardship households is necessary.

The guiding idea in the work of giving assistance to hardship households in Chuxian Prefecture is "helping the poor entails helping their will, and helping their will entails helping fundamentally." By "helping will" is meant teaching those to be helped to develop the will and the courage to shake off poverty and, with appropriate outside help, to rely mostly on their own efforts to overcome hardships, increase income, and guard against developing a mentality of dependence. By "helping fundamentally" is meant helping those needing help to develop production in order to solve their problems in a fundamental way rather than simply give them relief. Of course it is also necessary to give hardship households a certain amount of help to solve their real present hardships so that they will be able to take the first step along the road to the development of production. Specific ways of doing this are as follows:

(1) Formulation of standards for "helping the poor." In general such standards should include: those who lack a principal worker, or those whose principal worker has been ill for a long time and who do not have enough income to maintain the minimum local living standard; those who have little accumulated wealth, are deeply in debt, and lack minimal implements and funds for production as well as the necessities of life; those who have sustained natural or man-made disasters and who are unable to shake off adversity through their own efforts within a short period of time; and male and female children who have not yet reached adulthood who are carrying heavy burdens and whose lives are extremely hard. Those who lack will and depend on others, or do not work and are hard up as a result should not be objects for "help to the poor" in most cases. However, they should be

helped develop will and courage. Pacts should be concluded with them to guarantee production, and they should be supervised and encouraged to take the right road.

(2) Determine who is to be given "help to the poor." A thorough survey of hardship households has to be done first; and they should be registered and recorded. Then the masses should hold discussions for evaluation purposes; production brigades should investigate; communes should approve, and finally the facts should be publicly posted. Every effort should be made to avoid omissions so that the masses will not be dissatisfied and so benefits from "help to the poor" will not be impaired.

(3) Support with funds. In general goods, not money, should be given. Most of the things given should be those that can be used in agricultural sideline production such as chemical fertilizer, seeds, pesticides, as well as piglets and chicks. Second should be clothing and home building materials for use in daily life.

(4) Help with workers and skills (both for production and for daily life). Generally such help should be given by setting up "mass help teams." Laian County also used a system whereby cadres were made responsible for households in "helping the poor." Cadres above the County Science Bureau level and most cadres in districts, communes, and production brigades set up associations of households responsible for helping the objects of the "helping the poor" effort to formulate measures for throwing off their poverty and to help them plan production and daily living with someone being responsible for everything.

(5) Priority care in production conditions. This includes priority in contracting land, for example, priority in providing for use of draft animals, farm implements, and machines; priority in water supply; priority in supply of chemical fertilizer, pesticides, and superior seeds, etc.

(6) Lightening or exemption from responsibilities in many ways. This includes production team reduction or exemption from withholding quotas; commune and brigade enterprises reduction or exemption of processing fees for grain and edible oil; medical department reduction or exemption from some medical fees; water conservancy department reduction or exemption of fees for water; education department reduction or exemption from various school fees; priority supply of goods at list price by departments concerned, etc. However, opinions vary on this.

(7) Regular inspection of results from "helping the poor." From the foregoing specific measures may be seen that "help to the poor" differs from simple social relief. It is not simply bringing income to a common level, and much less is it robbing Peter to pay Paul, but rather is an effort to improve the relatively poor production conditions and individual capabilities of hardship households so that they will be able to use on generally equal terms with others the opportunities to become rich that they

are unable to use to the full by themselves, and to actively engage in agricultural sideline production, thereby increasing their own income levels and getting rid of poverty. Therefore, correct "helping the poor" neither leads to egalitarianism causing production efficiency to decline, nor does it widen the gap between rich and poor thereby impairing social order and economic development.

IV. Direction of Flow of Workforces and Funds

Following double contracting to individual households in Chuxian Prefecture, peasant investment of effective manpower greatly increased and ineffective manpower greatly declined. The amount of funds peasants possessed increased. A new trend toward excess manpower and funds appeared.

1. Increase in Surplus Rural Labor

As the efficiency of agricultural production increases and the working population increases, a surplus of rural workforces has become apparent. This surplus is both a year round one and a seasonal one. It has been calculated that about 20 percent of Chuxian Prefecture's agricultural workforce (or 220,000 people) could leave the land all year round, and the number is continuing to grow. This is because of the following:

First, though the speed of population increase may possibly slack, the speed of increase in the workforce is still rapid. About one-half of Chuxian Prefecture's 3.34 million population is under 19 years of age. In any given year in the future, the population coming of working age far exceeds the population that is retiring. If ages 18 to 60 are considered working ages, the prefecture's working age population will increase by 46 percent over the next 10 years, and by 62 percent during the next 18 years.

Second, the cultivated land area is shrinking. In 1980 the amount of cultivated land per capita of the agricultural workforce averaged 5.41 mu, 43 percent less than the 9.54 mu of 1952 for an average annual incremental decline of 2.01 percent. As a result of increase in the working age population, even if the cultivated land area shrinks no further, it is estimated that within the next 18 years, the amount of cultivated land per capita of the workforce will be 38 percent less than it is today, for an average annual 2.65 percent incremental decrease, which is faster than the incremental decrease of the past 28 years.

Therefore, if no major changes take place in the current rural employment structure, the surplus workforce will double within 5 years after the beginning of the 1980's, and will triple within 10 years. It will be 40 percent of the total agricultural workforce at the time. It will not be until the 1990's that the speed of increase in the surplus workforce will slacken (See Table 2).

If one says that the present 220,000 surplus rural workforce has not yet caused any obvious bad effect, the 470,000 of 5 years hence or the 710,000 of 10 years hence will exert considerable pressure on society. To rely on nearby cities to take that much surplus workforce in the future is very difficult to imagine. Therefore, various preparations must be made to transfer agricultural workforces as soon as possible.

Table 2. Change Trends in Chuxian Prefecture's Surplus Rural Workforces

Year	Agricultural Workforce (10,000)	Average Amount of Cultivated Land Per Capita of Workforce	Surplus Rural Workforce		
			Quantity (10,000)	Increase From 1980 (%)	Percent of Agricultural Workforce
1980	116.9	5.35	23.3	--	19.9
1985	143.4	4.36	47.0	101.7	32.8
1990	170.2	3.67	71.0	204.7	41.7
1995	185.2	3.38	84.4	262.2	45.6
1998	189.7	3.30	88.4	279.4	46.6

2. Improvement in Rural Capital Situation

Production cannot develop with a workforce alone. For many years a vicious cycle has existed in rural villages of "lack of investment—slow development of production--low labor productivity rate--slow accumulation of capital--lack of investment." The party's rural economic policies have caused Chuxian Prefecture's agricultural production to begin to break this vicious cycle, with the result that the rural capital shortage situation has taken a fairly clear turn for the better. This has increased investment in agricultural production and brought the prospect of fine development.

Formerly the rural collective economy made distributions only after having deducted production expenses, and commune member earnings were used substantially for consumption. Following the contracting of work tasks to individual households, both agricultural production expenses and investment in fixed assets were paid for largely out of the earnings of peasant households themselves; peasant income was no longer consumption funds. Survey showed the ratio between peasant household daily living payments and production payments to be basically 30 percent to 70 percent. Among production type payments, agricultural production expenses accounted for more than 60 percent, and production of fixed assets, industrial sideline occupation raw materials, and other production type payments each amounted to more than 10 percent. Among daily living expenses, food accounted for more than 50 percent; clothing, housing, and consumption goods each accounted for more than 10 percent; and other expenditures were less than 10 percent. These circumstances should be given attention when formulating rural economic policies.

Following double contracting to individual households, because the peasants' personal welfare was closely linked to results in agricultural production, enthusiasm for production increased, voluntary contraction in the ratio of spending occurred, and increased investment in production became the trend. During the past 3 years the Chuxian Prefecture supply and marketing system's sales figures for the means of livelihood have increased at a rate of less than 10 percent, but its sales figures for the means of agricultural production have increased year after year by more than 20 percent, including a 29 percent increase in 1980.

Today a considerable amount of currency that can be used for the purchase of things is in the hands of the peasants. How to make this money that is waiting to be spent play a constructive role in development of the national economy without impacting on the market is a problem requiring meticulous study and conscientious treatment. Just what the prospects and results are for peasant pooling of funds for partnership operations and of encouragement to peasants to invest in the collective or even in state-owned enterprises should be thoroughly explored.

It has to be appreciated that rural villages have just now solved problems of sufficient clothing to keep warm and enough food to eat, that they have just begun to accumulate some funds, and that development of agricultural production urgently requires funds. Investment capabilities and needs for expansion of reproduction are far apart. Under these circumstances how to induce the peasants to make rational use of these funds holds very great significance for China's rural development. It is necessary to proceed on the basis of gradual increase in peasant spending on living to planned encouragement and guidance to peasants for productive investment. Attention should be directed to avoidance of premature spending beyond levels of production. For example, for the time being there should be no publicizing or encouragement to peasants to travel to distant places.

3. Within the short term, emphasis should be placed on development of economic diversification on a family scale.

In a situation of many laborers and little capital, how can surplus rural workforces and limited capital be put to work in a fairly rational way. How much capital is required per worker in the production process is a major indicator in judging the capabilities of various sectors of the rural economy to absorb the surplus workforce. The experiences of Quanjiao County show that the amount of capital required per workers in a commume or brigade enterprise averages 3.8 times that for workers engaged in economic diversification on a family scale. The amount of fixed assets used by the former is 8.1 times that of the latter. For every 10,000 yuan in fixed assets, 10 people can be placed in a commune or brigade enterprise. Used in economic diversification on a family scale, 81 people can be placed. In addition, in overall terms, speed of accumulation of capital from economic diversification on a family scale is faster than for commune and brigade enterprises. Calculations show that for every 100 yuan of capital invested in Quanjiao County, commune and brigade enterprises could produce 71.59 yuan net income per year, while family scale economic diversification could produce 233.33 yuan of net income, which was 3.3 times the former. Thus, the rate of productivity of the latter's fixed assets was 4.1 times that of the former.

Formerly under circumstances of limited peasant operation of industrial sideline occupations and in which industrial and agricultural product comparative prices were inequitable, commune and brigade industrial enterprises played an active role in solving the problem of rural capital shortage. In the future, with readjustment of the national economy and changes in rural production relationships, existing commune and brigade industrial enterprises will have to try to develop in the midst of readjustment and do the necessary restructuring to meet changes in rural economic life. In their operations, they will have to stress production of products for which raw materials are plentiful, energy consumption small, and for which markets can be found. Examples are farm implements and building materials that are urgently needed in rural villages now. These should be underscored. However, in order to make the capital in peasant hands achieve greater use and make peasant enthusiasm for productive activities greater, as far as Chuxian Prefecture is concerned, for the short term the emphasis should be on development of family scale economic diversification. Not only does family scale economic diversification take little capital, but for the same amount of capital the rate of production is vastly higher than that of commune and brigade enterprises, and for investment of the same amount of capital in families, a greater amount of surplus workforces can be absorbed. Therefore, directing the flow of labor and capital to family scale economic diversification great significance as a way of solving the problem of excess rural labor, making full use of the role of limited capital, and increasing results in the macroeconomy. On this basis, large numbers of peasant households with double occupations will come into being, and there will be increasing differentiation of specialized households to change the trend of decline in the per capita amount of cultivated land.

Under existing market control circumstances, price policies play a substantial guiding role in the flow of rural labor and capital. In formulating price policies, the state should make an all-around evaluation of production potential, market potential, and of the consequences of labor and capital flow.

Right now a certain blindness exists in the movement of labor and capital. In some areas, too many industrial and commercial service industries are being operated in excess of actual needs, while some matters of economic diversification holding prospects do not develop as they should for lack of sufficient support. Some places having no assurance of fuel supplies buy trucks and tracts for agricultural use, and in some peasant households there are symptoms of lack of concern for continued development of grain production. In handling these matters, leadership departments should use economic methods, legal methods, and necessary administrative methods to intervene and give direction.

V. Prospects For Cooperative Association

During the last 2 years various kinds and forms of cooperative associations have come into being in the development of the rural economy. We also observed and studied the present state and prospects for these new cooperative association forms.

1. Present status of cooperative association

According to incomplete statistics from Chuxian Prefecture dated May 1981 in addition to a large amount of seasonal and temporary simple cooperation among peasant households, there were a total of 6,114 fairly stable economically associated groups participated in by 26,865 households on 14 kinds of undertakings throughout the prefecture. This was 4.5 percent of the total number of peasant households. Directly engaged in associated undertakings were 23,441 people or 2.1 percent of the prefecture's total workforce, an average of 4.4 households per associated group, with 3.8 people per household participating in endeavors directly.

This new associated groups are distributed largely in the three counties of Dingyuan, Fengyang, and Jiashan, which instituted the contracting of sole responsibility for work tasks to households fairly early, where the foundation for collective industrial sideline occupations is shaky, where state requisition base figures are fairly low, and where capital has accumulated fairly rapidly. Statistical data from Jiashan County shows that the speed of development of associated groups has been fairly rapid as follows: As of April 1981, associated groups numbered 1,078. By August the number had grown to 3,909 for a 262 percent increase. The 4,415 participating households grew to 21,411, a 385 percent increase and 24 percent of the county's total number of peasant households.

The specific form of Chuxian Prefecture's cooperative and associated groups may be divided into three kinds in terms of the relative degree of their agriculture in a narrow sense. The first kind is cooperation and association directly in the production process in a narrow sense and in economic diversification, which accounts for 91.7 percent of all households in associated groups. The second kind is associated groups in manufacturing industries and doing preliminary processing of agricultural products, which account for 7.2 percent of the total number of associated group peasant households. The third kind is associated groups in business and the service trades, which number 1.1 percent of all peasant households in associated groups. Distribution of already formed associated economic groups in 23 different kinds of activities is shown in Table 3.

Table 3. Distribution of Associated Economic Groups Engaged in 23 Kinds of Activities

	Category 1						Category 2											Category 3					
	Tractors	Plant Protection	Tobacco Curing	Seed Production	Seedling Growing	Fish Raising	Grain & Cotton Processing Plant	Wheat Flour Workshop	Bean Curd Workshop	Edible Oil Workshop	Kiln	Phosphate Fertilizer Plant	Cement Plant	Quarry	Wood and Iron Workshop	Construction Corps	Cultivation and Processing Plant [1014 0455 1681]	Trade Goods Storage	Retail Shop	Restaurant	Inn	Transportation Corps	Cinema Team

The need for cooperation and association was born, first of all, in the direct production process in agriculture after which it grew into associated groups in industrial sideline occupations, in business, and in the service trades.

2. Several Characteristics of Cooperation and Association

First, the new associated groups fundamentally have to do with association before farming and after farming, as well as to the simple cooperation occasioned by the seasonality and sudden needs of farming itself.

Second, most of the new associated groups have taken the form of being loosely affiliated but not combined. Each participant does an independent economic accounting, becomes a shareholder voluntarily, withdraws voluntarily, and individual households may be a part of several associated groups at the same time. At the time they are set up, either a number of people equivalent to the number of shares bought are employed, or shares are bought according to the amount of funds available and the number of people to be employed is set according to production needs. Mostly distribution is done in accordance with work, bonusus in accordance with the amount of shares purchased being ancillary.

Third, currently these associated groups are still in their formative stages. Concentration of able farmers in the farming industry and concentration of skilled craftsmen in industrial sideline industries is only just beginning to appear, while economic association of specialized peasant households or economic association based on specialized division of labor is a rarity in actual rural economic life.

The reasons for the rapid development of new economic association in Chuxian Prefecture and the reasons they bear on such a wide range of activities are as follows:

First is liberalization of policies and the peasants having self-determination. Not only have restrictions on private individuals not being permitted to buy machinery been lifted, but support has been given such purchases by installment plan buying. Not only are peasants permitted to go in for economic diversification, but they are allowed to open retail shops and run industrial plants. Only in this way has it been possible for new economic associations to come into being in Chuxian Prefecture.

Second is the existence of surplus labor and idle capital. Following the contracting of full responsibility for work tasks to individual households, the trend toward change in the structure of the rural workforce was one of "three increases and three decreases," by which is meant an increase in the amount of effective labor, and a decrease in the amount of ineffective labor; an increase in the amount of labor employed in multiple industries, and a decrease in the amount of labor engaged in agriculture; an increase in auxiliary labor, and a decrease in labor by women. The labor surplus in agriculture that had been covered up by the "great hullabaloo," was brought out into the open. Take Kaocheng Commune in Fengyang County, where there are a fairly large number of economically associated groups, for example. Kaocheng Commune has a workforce totaling 7,200 people, each member of the workforce being responsible for farming an average of 4.4 mu. According to calculations we made about the number of workers needed to farm various crops, 2,700 workers would be needed for the somewhat more than 30,000 mu in the commune. Calculations made from a representative sampling of households showed household sideline occupations requiring a workforce of 1,200 people, so the surplus workforce amounted to more than 45 percent. The surplus labor and idle capital had to join together for development in depth and in breadth.

Third is changes in market conditions. With development of production and increase in income, gradual increase occurred in peasant demands for the means of livelihood, the means of consumption, and for services in their daily lives. However, on the other hand, some commune and brigade enterprises in the existing collective economy that had a shaky foundation, a bad attitude toward service, and poor results from their operations, became mired in a state of paralysis and stagnation one after another. Their supply of the means of production was inadequate, channels for the flow of materials became clogged, and sharp conflicts between supply and demand occurred. In such a situation, peasant household investment of funds had an extremely powerful attraction. The peasants hoped to rely on their own strength to bring about many channels of flow for materials and to blaze new production trails.

3. Socio-economic Results

Comrades in Chuxian Prefecture said that the new economic association groups made the most of strengths in contracting full responsibility for completion of work tasks to individual households and made up for shortcomings in such contracting. This made sense. With the establishment of associated groups by contract households, this form of organization that helped development of production was better able to effectively increase the socio-economic benefits of agriculture.

First, it brought into play the initiative of both individuals and collectives in the farming industry. Formerly when the "great hullabaloo" was practiced in agricultural production, the relationship between the labor contributions of commune members and the remuneration of labor was expressed through the medium of workpoints. However, practice has shown that the workpoint system cannot effectively put into effect the principle of distributions according to work. On the one hand this system hurt individual commune member enthusiasm for labor, and it also did not allow productivity from cooperative production to develop. The responsibility system of contracting full responsibility for completion of work tasks to individual households effectively solved the first of these two problems;

nevertheless, it also gave rise to farming by independent households and further development of conflicts in production. Economic association solved these conflicts. While maintaining the responsibility system of contracting full responsibility for task completion to individual households, it brought about working in cooperation, expansion of space for reproduction, shortening of work hours, and a saving in both living labor and embodied labor. Its basic principle is decentralization of whatever should be decentralized, and centralization of whatever should be centralized. An example is the associated tractor team in Taiping Commune, Jiashan County, which instituted cooperation in the planting, tending, and harvesting links of grain production; and used machines more beneficially than had been possible by individual households in the production links of plowing, harrowing, hauling, and threshing. These methods were hailed by all the peasants.

Second, the new economic association helps both skilled farmers and skilled craftsmen make the most of their technical specialities and to gradually move from the foundation of contracting full responsibility for work task completion to individual households toward specialized production. In the former collective economy, as a result of egalitarianism and not being able to do work suited to one's abilities, the special skills of people were held in check, while at the same time some specialized division of labor became a privilege. Following the contracting of full task completion to individual households and the emergence of economically associated groups, an effective way in which to solve the foregoing problems was provided. In the production of tobacco, for instance, where it was not economical for individual households to set up curing rooms, when several households cooperated, the time for growing of seedlings, tending them and curing the tobacco would be largely identical. In this way, those skilled in the growing of tobacco would constitute the nucleus in getting together various households in association. Skilled tobacco grower Fu Ronghuai [0265 3837 2037] of Qiandong Production Team in Qiaotou Commune, Jiashan County had an annual income of 260 yuan solely from the growing of tobacco seedlings for three production teams. In growing the seedlings, he put the seeds that had been soaked into plastic bags, and when he went into the fields to work, he hung them on his clothing next to his skin, and when he slept, he put them inside the bed clothes until they had all sprouted. After planting them, he carefully tended them.

Third, the new economic association provided a workable organization form whereby rational arrangements could be made for use of manpower, capital, and natural resources. The contracting of full responsibility for work task completion to individual households had tapped production potential and steadily brought into being surplus labor and idle capital. How to make the best use of them and use them in expansion of agricultural reproduction and rural economic construction became a great problem. For example, in Kaocheng Commune some peasants had money with nothing to spend it on, so they frequented taverns, got together to gamble, and even made usurious loans, or went by train to Pangfou to carouse. After associated groups were set up, the considerable amount of idle funds in the hands of peasants were combined with the surplus labor and invested in expansion of reproduction.

Today, 85 of the 183 peasant households in Kaocheng Commune jointly operate integrated industrial and business associated groups for processing of grain and edible oil, and to do electric welding. They have purchased 47 tractors for a total investment of 188,700 yuan. Associations of peasant households in Taiping Commune invested 402,200 yuan in the purchase of tractors alone. This has not only converted dead money into live money, but large amounts of surplus labor have also been soaked up by these associated groups.

Fourth, the new economic association has promoted readjustment of the rural economic structure and has provided a stepping stone for the transition of the rural economy from what is substantially self-sufficiency production to a commodity economy. The former collective economy was engaged throughout in substantially the same kind of activities, and there was little division of labor for production of various kinds. In addition, workers within the collective economy were restricted to relatively unchanging work hours. For example carpenters and blacksmiths in production teams were generally responsible only for repair of the production team's farm tools and spent the rest of their time farming. Such an economic structure, whose horizons were the production team, was totally demolished by the contracting of full responsibility for task completion to individual households, and the new economic association provided an embryonic form for development of a new economic structure.

Fifth, the new economic association posed new demands for reform of the rural economic structure. Responsibility systems linked to production are a starting point for reform of the rural economy, and the birth of new economic association has strengthened this tendency. In Qiaotou Commune, for instance, there are two grain and cotton processing plants, one of which is operated jointly by peasant households and one of which is commune operated. The processing plant run jointly by peasant households does not have great resources by any means, but it stresses economic results, flexible methods, and thoughtful service, and it cares a great deal about its reputation. As a result, it has become dominant in competition with the commune run plant, and customers flock to its door. Though the commune run plant has better buildings and equipment than the plant run jointly by peasant households, it had to stop work for 2 months because of poor management, decline in earnings, and inability to pay wages. Finally it had to cut half of its employees and change from eating out of a large common pot to a system of contracting full responsibility for work task completion. This showed us that in reform of the rural economy it is possible to use a minimal social shock to gain very great results and, without directly changing the old system in name, to bring about gradual evolution of its actual content. This is advantageous, of course, in reform.

Double contracting to individual households is a basic condition for the existence and development of the new cooperation and association. For a substantially long period of time, the responsibility system of double contracting to households must remain stable and not be lightly changed. Any of the production links in farm that can be done independently by peasant households can also use cooperation and association, with peasants themselves feeling their way toward solutions in practice, the principles of voluntary participation for mutual benefit, and centralizing whatever lends itself to centralization while decentralizing whatever lends itself to decentralized being followed. There should be no artifical organization of cooperation and association, and care should be taken not to start a movement on a grand and spectacular scale, rushing headlong into rash action only to break up in a hubbub.

One can also not take an entirely laissez-faire attitude toward peasant cooperation and associated groups, but rather should set up statistical and supervisory systems, and use economic methods to put peasant associated groups on the path toward being a part of state plan. Financial departments should set up bank accounts for them, make loans to them, and take in their savings. Vocational departments concerned should help them set up responsibility systems and contract systems in cooperation, train management and technically skilled personnel in an organized fashion, gradually improve the cultural level of participants, and train cultured businessmen. Distinctions should be made in taxation, low profits being taxed low and high profits being taxed high. For associated groups having exceptionally high profits, accumulative total taxes should be levied, but this should be done loosely at first with tightening taking place later on, both so that the associated group can make a profit and so that the state will gain a definite economic benefit.

VI. Establishing an Equitable Economic Functional Structure

Rural establishment of a socialist collective economy was a correct choice made by the masses of Chinese peasants under leadership of the party. Following establishment of the collective economy how to put it on the track of a management system suited to circumstances in China has been a process requiring steady practice. For a long period of time the system whereby politics and communes have been linked has resulted in the management function in China's rural economy being overly centralized. This has inhibited giving full play to the enthusiasm of the peasant masses and of rural cadres, and abuses have been extremely obvious. But institution of production responsibliity systems has led to thoroughgoing changes in the rural management system. We devoted a lot of study and attention to these changes in Chuxian Prefecture.

1. Peasant Households Have Taken on Some Management Functions

The trend in rural Chuxian Prefecture that has aroused most attention during the past 2 years has been increase in the role of peasants in economic life. A considerable part of the function of managing the collective economy has been taken over by peasant households. These functions consist largely of the following:

First, direct organization of production and labor by contracts. This has included the following: arranging for the sequence of crops to be grown on contracted land; preparations for production (machine and draft animal power, seeds, fertilizer, pesticides); decisions about and implementation of technical measures to increase production; allocation of household work-forces to plowing, planting, tending, and harvesting; maintenance and use of machines and equipment; exchange of labor, etc. The situation in which a small number of cadres were relied upon to get planting and harvesting underway every season is over. Farm work is as tiring as ever, but life has a rhythm. By effectively using their sparetime, peasants are able to manage their household affairs more smoothly than formerly, go to market or see a play, visit relatives and call on friends, and study cultural knowledge and farming techniques. This helps greatly in improving reproduction and the quality of rural life. The tremendous all-around increase in agricultural production throughout the prefecture shows that the peasant household take over of these functions makes sense and is effective.

Second is accumulations. Accumulations that peasants have turned over to the collective are greater than in previous years. At the same time peasant households are engaged in accumulating themselves. In 1980, peasants in the prefecture put out their own money to buy 126 large and medium size tractors, 1,933 hand held tractors, 1,926 processing machines, 18 farm motor vehicles, and 25,298 plow oxen. In the same year production funds increased by 23 percent over the previous year, and this could not but greatly increase agricultural reproduction capacity. At the same time, peasant households invested funds to buy shares for participation in commune and brigade enterprise reproduction.

Third is credit. Banks are changing to make households the unit to which they grant credit. In Tianchang County, 24,000 households have set up credit accounts. Agricultural banks in all counties report that peasant household creditworthiness is much better than production team's had been. Dingyuan County formerly had 500,000 to 700,000 yuan in unrecoverable loans annually. In 1980 1.8 million yuan of loans were issued to peasant households and 1.87 million recovered the same year (700,000 yuan being old loans). Last year Jiashan County overfulfilled by 14 percent its loan repayment plan.

Fourth is distribution and supervision. The former overconcentration of the management system meant that a small number of people had too much power while the democratic rights of the peasant masses and lower level cadres were comparatively few. Some of the apathy about work of the peasant masses resulted from protest against this state of affairs. Moreover, the poverty ensuing from apathy about work made eating more and consuming more increasingly rampant in a vicious cycle. Today, once a peasant household has turned over to the state the amounts stipulated in contract agreements, all the remainder is its own. Thus, not only is the portion of total earnings that the peasants get greater, but the peasants can refuse to pay for unreasonable expenditures and prevent cadres from spending freely and wasting. This protects the fruits of the peasants' labors, protects collective property, and protects cadres.

As the economy develops, functions taken over by peasant households will also undergo change and new combinations will be formed. (1) Some peasant households already show a tendency to develop into specialized households. Survey of 20 different kinds of communes in the prefecture shows a 24.1 percent increase in 1980 as compared with the year before in income from peasant family sideline occupations. Quite a few peasant households actively farm economic crops from which earnings are relatively high (oil-bearing crops, mat grass, peppermint, mulberry, and hemp), engage in the breeding industry (cattle, sheep, hogs, poultry, rabbits, bees, fish, and silkworms), processing, hauling, small business, weaving, and services. The first signs of specialized division of labor have also begun to appear among peasant households. Some things requiring a fairly large amount of skill such as breeding, growing of seedlings, curing of tobacco, and the five rural crafts [masonry, carpentry, pastering, bricklaying, and bamboo work] have already begun to be taken over as specialities by some households. These changes will further expand the scope of peasant household operations, and will make for diversification a closer relationship among rural households and the entire society. (2) A large number of peasant households working on the principle of voluntary participation for mutual benefit have teamed up to contract commune and brigade enterprises such as individual peasant households would not be able to manage alone. With the surplus labor in households and accumulations of capital, some associated groups for which commune members have themselves put up the capital have come into being. Thus, differing forms of cooperative organizations are gradually becoming new economically beneficial entities. Not only do they engage in complex associations and exchanges with peasant households and other economic units, but also generate and produce within associated groups plans, management, distribution, accumulation and such new functions. Though peasant household association is embryonic today, it holds prospects for greater capacity and expanded development.

2. Necessary Collective Organization Management Function

After some economic functions have been transferred to peasant households, will the collective economic organization still have to be responsible for necessary economic functions? The answer is affirmative.

Existence of the collective economy is an objective necessity for development of the economy. A look at Chuxian Prefecture shows, first of all, an annual flow between cities and countryside of several hundred million yuan work of industrial and agricultural products. Only a collective economic organization is able to take on the exchange of goods with centralized industries and cities.

Secondly, that portion of agricultural skills that cannot be mastered and spread through the accumulation of experiences of individual peasant households is on the increase. More and more peasant households must obtain information about agricultural techniques. Only by banding together can the 600,000 peasant households in the prefecture obtain technical information smoothly. This accounts for the emergence of a flourishing of all levels of scientific farming organizations, scientific technique responsibility systems, model households for farming techniques, and peasant scientific societies.

Next, some regulatory functions related to the welfare of peasant households themselves such as "assistance to the poor," handling of quarrels about water use, readjustment of the land, etc., obviously require a structure and organization responsible for handling.

Finally, peasant households may not give serious attention to matters such as population increase, ecological balance, restrictions on use of cultivated land, things that pertain to macro-economic benefits, things that relate to the long range interests of all the people including peasants, and things in economic life that may frequently conflict with the immediate interests of the peasants. One could not expect that such matters would be managed entirely by peasant households themselves.

The foregoing several matters occur mostly in the indirect economic process. Even in the direct production realm, peasant households cannot take responsibility for all activities. For some matters, neither individual peasant households nor present associated groups of peasants have the strength to undertake. This includes things such as emergency resistance to disasters, construction of fairly large water conservancy projects. large scale native handicraft trade, etc. In some cases it does not pay for individual peasant households to do things; only with organization can they be profitably carried out, and this requires that the collective economy take responsibility.

All this has determined that even in Chuxian Prefecture, which has instituted large scale contracting of full responsibility for work tasks to individual households, the collective economic organization has not and cannot transfer to peasant households all of its economic functions. What has happened here has been transfer of only a portion of economic functions. To a fairly large extent, production policy decisions, operating strategies, and accounting continue to be the responsibility of the collective economic organization.

In addition, during the past more than 20 years both common property has been accumulated and common debts incurred. The two are a material bond that binds peasant households together.

All these connect and reflect the stratification and diversity of rural economic relationships. Today in Chuxian Prefecture, there are four major strata: (1) peasant households; (2) associated peasant entities; (3) state-owned or commune and brigade operated economic organizations; and (4) commune and brigade organizations directly interlinked with state organizations. No matter how large a portion of economic functions peasant households take over, they are still linked in these ways. All these links have as a premise the public ownership of land; all take place under guidance of state plans; and all are under the leadership of the party. Consequently, the sum total of these links comprise the existing socialist economic relationships of China's rural villages.

3. On the Economic Functional Structure

Practice has brought about an economic functional structure suited to circumstances in China's rural villages. Individual economic functions are largely undertaken by peasant households, peasant associated groups, communes and brigades, and the state in rural economic organizations. Through the establishment of individual functional organic links, coordination of the welfare of the country, the collective, and the peasants is realized.

In a certain sense, rural organizational problems are problems in establishment of an equitable functional structure.

Proceeding from the existing system and acting to depart from past practice whereby a small number of people monopolized economic functions, transferring to peasant households those things that can truly be undertaken by peasant households while having existing commune and brigade organizations more effectively undertake to carry out the remaining portion for a gradual change in the old structure and formation of a new structure is a path that can be taken for reform of China's rural system.

The problem facing Chuxian Prefecture right now is that once some economic functions have been effectively turned over to peasant households, how to take care of the other functions that peasant households are unable to be responsible for. Unless all strata and all parts of economic functions are well coordinated, the microscopic benefits already gained may be offset by the macroscopic ones. Therefore, following double contracting to individual households, all socio-economic management work has to be done truly well.

VII. Status of Rural Cadres

In China the job of managing the rural economy is largely the responsibility of commune and brigade cadres. Chuxian Prefecture has more than 83,000 commune and brigade cadres today. The prefecture, with a 2.95 million population or 604,000 peasant households engaged in agriculture has an average of one cadre per 35.2 people or 7.2 households. This cadre corps plays a particularly important role in protecting the fruits of rural economic reforms and in advancing its further development.

1. Rural Cadre Earnings

We surveyed the changed situation in economic income for 54 commune and brigade cadre households at different economic levels in Dingyuan, Fengyang, Jiashan, and Quanjiao counties, the results of which showed the following:

Average income for 35 commune cadre households as figured on the comparable portion of former collective distributions showed an increase from the 38.96 yuan prior to double contracting to individual households to 114.24 yuan in 1980, a 20.91 percent increase (not including individual cadre income from wages). The aforestated income for 12 production brigade cadre households rose from an average 64.87 yuan per capital to 171.24 yuan, a 163.97 percent increase.

The average per capita 295.50 yuan subsidy that production brigade cadres received and the 62.60 yuan that production team cadres received constitutes the current [character mission] level of rural cadre subsidies. Looked at in terms of the extent of income increases, for the prefecture as a whole average per capita income in 1980 was 56.1 percent higher than before double contacting to individual households. In the four aforementioned counties the extent of increase in per capita income was lower than the extent of increase in average per capita income in 54 cadre households. The reasons for the faster increase in commune and brigade cadre economic income were as follows: (1) Vastly increased amount of labor invested. Today cadres have really "dropped from the embankments between fields into the fields themselves" where they really work in earnest. Most production brigade and production team cadres put in 220 - 330 working days a year. (2) Cadres conduct liason over a wide area; they are well-informed; and they possess fairly strong administrative skills. (3) In the use of production conditions such as use of plow oxen, use of water, purchase of chemical fertilizers, making loans, and getting workers to help, they provide real services. For all these reasons, the double contracting to individual households rapidly turned into economic income for cadres.

For this reason, not only did double contracting to individual households cause no drastic impairment of commune and brigade cadre households, but rather they benefitted from double contracting to individual households. This has been a basic reason why the broad masses of cadres have adopted a positive and active attitude toward promotion of responsibility systems (including cadre personal responsibility systems), and it has also been an important experience whereby Chuxian Prefecture leaders have benefitted and double contracting to households has achieved remarkable results.

2. Quality of Rural Cadres

The above circumstances is not to say by any means that the state of ideology and work of the cadre corps already meets requirements following establishment of responsibility systems. After double contracting to individual households had been practiced for several years, in particular, numerous new problems that had never before been encountered cropped up in rural villages, and grassroots level rural cadres were by no means able to solve these problems very well. This gave rise to the unsuitability of cadre quality. In Jiashan County a commune secretary said, "Today minds are a little blank; work is a little lax; and numerous problems cannot be understood." According to a survey done by the Prefecture CPC Committee Organization Department of 68 committee members of a commune CPC Committee and 209 branch committee members of 41 production brigades, incompetent leaders at the two levels numbered 17.6 and 18.3 percents respectively, and those who did not know their jobs well amounted to 13.2 and 9.6 percent respectively.

Unsuitable cadre quality is harder to overcome than political opposition attitudes. This is because quality of management cadres is formed under certain historical conditions. Rural cultural levels in China are backward, and the "large in size and collective in nature system" [of communes], leftist errors, and the proliferation of political campaigns have all been bad for improvement in cadre management levels. Today when it is both necessary and possible to improve the quality of rural cadres, efforts are limited by the age and cultural level of these cadres. We compiled statistics on 11 communes in five counties and the organization departments of the Jiashan and Fengyang county CPC committees compiled statistics on 5,052 commune and brigade cadres in 80 communes, which found 9.7 percent to be illiterate, 50 percent to have a primary school education, and only 7 percent to have a higher than senior middle school cultural level. Those above 45 years old numbered 27.3 percent, and those who served as cadres during the period of land reform and the founding of cooperatives numbered 32.9 percent. The old age and low cultural level of rural grassroots cadres is striking. The cultural level of first tier commune cadres is fairly high (71.7 percent above the junior middle school level), but they tend to be old (51.3 percent over age 45). By comparison, production brigade and production team cadres are in the prime of life (78.3 percent being below age 45, 44.95 percent of these being under age 35), but their cultural level tends to be low (an illiteracy rate of 11.8 percent and 55 percent having only a primary school education); 66.8 percent of cadres became cadres during the "four clean-ups movement" [the period 1963 - 1966], and during the Great Cultural Revolution, and their cultural level is slightly higher and their ages slightly younger. However, the historical period in which they came to maturity was not conducive to formation of good quality.

3. Need for Relative Stability of Rural Cadre Corps

Is it possible to make large scale replacements of the existing cadre corps? In order to answer this question, we observed and studied how those with organizational ability in rural villages emerge, i.e., those with possibilities for replacing the present cadre corps.

First the number of cadres nationally who want to become commune cadres is extremely small. University and technical middle school graduates assigned to communes are even rarer birds, and most of them are discontent. Ability to come up from below is limited by city and town residence requirements; even if a person is able to transfer his residence registration to a city or a town, it is difficult for his family to do so. Tianchang County is able to change the household registration to cities and towns of only 40 to 50 people a year, but there are more than 500 applicants.

Second, production brigade and production team cadres are all locally produced, and rarely are exchanges between one place and another made. Their successors can only be local peasants. Following double contracting to individual households, peasant welfare became linked to household farming of contracted land, and the interest of young, strong peasants in the study of technology and in undertaking economic diversification became very great. But desires to become cadres to manage joint undertakings declined. Cadre "seedlings" that had been selected were difficult to promote to positions of leadership. When some "seedlings" saw their prospective "cultivators," they fled as far as they could go. In addition, almost all formerly chosen cadres came from among the activists in various campaigns, and now that there are no more campaigns how to spot and train peasants with organizational abilities for economic activities is a long way from being worked up into a method. The situation today is one of it being easy to issue commands to leave at once, but summoning return is difficult.

Third, within the cooperative and associated peasant groups it is possible to bring to maturation management cadres possessed of new qualities. However, this process, like the development of associated groups, requires a long time. Jiashan County is the place where associated peasant groups have developed fastest, yet the average scale of associated groups is only four to seven households. This shows that the organizational management work of associated groups is still fairly simple. In some fairly large scale economic contracting groups, collective enterprises, and trade warehouse, leaders are either present cadres or past cadres. In Lianbu Commune in Dingyuan County, the director of a tea farm jointly contracted by 24 households was a "company commander" in a commune during the militarization period of 1958. Key personnel in the commune trade warehouse were accountants during the time of cooperativization. The Gaogang Production Brigade Phosphate Fertilizer Plant manager was a former production team head. The director of the Nianjiagang Commune trade warehouse is a production brigade party branch secretary transferred by the commune. The manager of the integrated agricultural, industrial, and commercial company of Kaocheng Commune in Fengyang County is a CPC committee secretary in the same commune. This shows us that the source of new quality management personnel can only be principally from the existing cadre corps.

Facts have shown that with the institution of double contracting to individual households, fairly rapid growth took place in rural personnel versed in single kinds of work of a technical nature that was small in scale, but that it has been extraordinarily difficult to get people who are able to undertake comprehensive, fairly complicated organizational management work. Therefore, full use must be made of the favorable conditions created by peasants currently taking over some economic functions to reduce the overall management workload and train cadres, raise their economic management levels, and continuously bring in new blood. There is no other choice. Any unrealistic evaluations, decisions, and policies in this regard can produce an unfavorable impact on further development of the rural situation.

PLANNING EMPHASIZED TO AVOID GLUTS, SHORTAGES IN LIVE HOG MARKETING

Beijing ZHONGGUO NONGMIN BAO in Chinese 26 Sep 82 p 1

[Article: "Improve Planned Marketing of Live Hogs in an Effort To Solve Peasant Difficulties in Selling Hogs"]

[Text] Frequently imbalance occurs in market supply and demand for live hog production. By this is meant that a large number of hogs are marketed during the peak period, but since market sales and commercial storage capacity is limited, not all the hogs that peasants want to sell can be accepted. As a result, to some extent peasants, experience "difficulty selling hogs." During the slack season, few hogs are marketed so market consumption requirements cannot be met. Commercial departments then have to mobilize the masses to sell hogs. Some comrades feel that it is difficult to understand why hogs are said to be numerous for a time and scarce for a time. Actually this is a reflection of the conflict between supply and demand that exists objectively in commercial work. In a situation in which lives hogs are substantially produced in countless dispersed households, it will not be easy to entirely circumvent this conflict within a short period of time.

Up until the time of the Third Plenary Session of the 11th Party Central Committee, growth in live hog production was unable to satisfy growth in consumption demand. After the Third Plenary Session, steady increase occured in the number of live hogs in inventory. The fattening period was generally shortened; the inventory removal rate increased markedly, and the amount of pork available greatly increased. When this happened, for a time seasonal and local peasant "difficulty in selling hogs" became fairly pronounced. As a result of the concern of the CPC Central Committee and the State Council, during the past several years commercial departments have intensified procurement, expanded marketing, built more cold storage facilities, and expanded storage in a series of measures taken to moderate year by year the contradiction of "difficulty in selling hogs." Nevertheless, in a small number of key hog producing counties, during the peak season of hog production, the cry of "difficulty in selling hogs" can still be heard.

Sole reliance on state-owned business procurement and storage to wrap up the problem is not a good way in which to solve the problem of peasant difficulty in selling hogs. The joint efforts of all departments concerned are necessary to improve planning in the marketing of live hogs.

First it is necessary to improve planning in removal of fattened hogs from inventory in order to avoid overconcentration during the peak season, and particularly during the hot months of June and July, of removal of fattened hogs from inventory. Nowadays some households that specialize in the breeding of hogs have begun to realize this. They plan the time for breeding of sows, the birth of shoats, and removal from inventory of fattened hogs, avoiding, insofar as possible, sales of fattened hogs during the stiflingly hot months of June and July. In essence, this amount to the application to the hog raising industry of "operations research," and "optimization," which should be vigorously encouraged. State-owned agricultural and livestock farms, collectively owned hog raising farms, households specializing in the raising of hogs, and key households can all do the same thing.

Second is detailed and solid work in live hog assigned procurement and planned procurement, in an effort to make purchases in a planned way to even out the market. This year commercial department signing of seasonal and monthly live hog purchase agreements with production teams or peasant households on the basis of assigned quotas and planned procurement quotas has played a definite role in the strengthening of planning. However, in some places, because there have been no fixed times established for sales in assigned procurement contracts, the peasants raise "quota hogs" during the first half of the year and "New Year's hogs" during the second half of the year. As a result, in these places during June and July markets "cannot get any," and during the last half of the year they "cannot take any." In some places production teams have not assigned state purchase quotas to individual households, so peasant sales of live hogs continue to lack planning. All this has to be conscientiously improved. In some places, once there is a surfeit of hogs commercial departments do not adhere to the effective and workable method of "going from door to door to inspect the hogs and setting up appointed times when they will purchase them"so as to avoid having the masses market their hogs blindly out of fear that they will be unable to sell them. Grassroots commercial staff and workers must persevere in going into the countryside to make purchases and to do a good job of publicity to set people's minds at ease. In places where a lot of buying and selling of hogs is done, commercial departments should also do a good job of organizational work for "earlier marketing" and "delayed sales" during the peak period, "evening out fluctuations," arranging marketing, and balancing purchases.

Third, looked at in long range terms, active development of lean hog types is necessary for gradual solution to the problem of insufficient lean pork and a surplus of fat pork. There are already considerable numbers of Landrace and large Yorkshire hogs everywhere, but because of the single kind of feed available for them, and commune and brigade bonus and price policies, and remuneration for collecting hog manure all encourage the raising of large fat hogs. As a result even lean pork type hogs have been turned into fat type hogs. This requires study and improvement from the standpoints of improved hog varieties, improved feeds, and perfection of economic policies in order to give impetus to rapid development of lean pork type hogs.

CENTRALIZATION OF IRRIGATION IMPLEMENTED IN BAODING

Shijiazhuang HEBEI RIBAO in Chinese 24 Sep 82 p2

[Article: "Some Production Teams in Baoding Prefecture Set Up Irrigation Companies; Institute Independent Accounting, Centralized Management of Farmland Irrigation, and Solution to Problems of Commune Member Water Disputes"]

[Text] As part of the process of perfecting agricultural production responsibility systems, some production teams in Baoding Prefecture have set up irrigation companies (some are called pump well irrigation companies or specialized soil irrigation teams) with specific responsibility for irrigating the land. This has gained acceptance by the broad masses of commune members.

After 86.9 percent of production teams in Baoding Prefecture instituted responsibility systems whereby work responsibilities were assigned individual households, some new conflicts cropped up in irrigation. Matters such as calculation of compensation to pump well operators, collection of irrigation fees, and deciding the precedence of land to be irrigated all required equitable handling to meet the situation following institution of responsibility systems. In addition, after assignment of work responsibilities to individual households, some households purchased their own equipment for raising water. With the increase in such equipment, centralized use became impossible with the result that equipment lay idle and funds were wasted. Furthermore, the frequency with which equipment was moved around caused serious damage to water conservancy facilities. Individual households that had privately purchased machines were also free to use them as they liked, so instances occurred in which they hiked irrigation fees.

In order to solve these new conflicts, some production teams set up irrigation companies, transferring to the irrigation companies all collectively owned water conservancy facilities, pump wells, and water lifting equipment, the company being responsible for safeguarding them. Acting on the principle of voluntary participation for mutual benefit, privately owned water pumping equipment as well as the equipment operators were made a part of the company. Economically the company instituted independent accounting, responsibility for its own profits and losses, enterprise-style administration, and was responsible for management and use of all of the brigade's drainage and irrigation facilities, becoming responsible for the irrigation of all farmland. The irrigation company strengthened administration and management, instituted personal responsibility systems for machinery operators, and assigned fields for which operators would be responsible for watering. In general, production team leaders came to an agreement with individual households about the time when their fields would be watered on the basis of field plot water requirements. The irrigation companies registered each well and collected fees on a time basis. Some collected fees on the basis of kilowatt hours used, and some collected fees on the basis of the number of mu watered. Jiaozhuang Production Brigade in Anguo County has 22 pump wells, 22 diesel engines, and 22 electric motors. After the production brigade established a pump well irrigation company, the company took responsibility for irrigation of the brigade's entire 1,783 mu, charging a fee of 0.07 yuan per hour of irrigation. This included a depreciation fee of 0.07 yuan to be used for equipment replacement, public accumulation and public welfare funds amounting to 0.13 yuan, and a management fee of 0.06 yuan, the three totaling 0.26 yuan, an equipment maintenance and repair fee of 0.07 yuan, and a fuel and electricity fee of 0.27 yuan for a total of 0.44 yuan under control of the pump operator, any savings belonging to him. The 11 diesel engines that the Luohe Production Brigade in Rongcheng County had privately bought, as well as 11 operators, became a part of the brigade's irrigation company. They worked 10 hours daily for slightly more than 4 yuan. This was beneficial to the collective and no loss for anyone.

After experience over a period of time, all the brigade operated irrigation companies in Baoding Prefecture demonstrated their superiority. The companies' centralized responsibility for irrigation changed a tumultuous situation that had existed in which no one had been responsible for irrigation and in which disputes over wells and pre-empting of water had occured. This solved problems for commune members in getting irrigation water and a chaotic method or irrigation. As a result of the specialization of irrigation company activities, a saving in manpower, in equipment, in fuel and electricity were effected; irrigation costs were lowered; the irrigation cycle was shortened, and the pace of irrigation hastened for a reduction in peasant economic burdens and intensivity of labor. This helped collective production and development of individual household sideline occupations, and increased economic benefits.

HEBEI

IDEAL TIMES FOR SOWING WINTER WHEAT IN HEBEI PROVINCE GIVEN

Shijiazhuang HEBEI RIBAO in Chinese 17 Sep 82 p 1

[Article: "The Right Time for Sowing Winter Wheat in Various Places"]

[Text] Sowing wheat at the right time is the key to development of sturdy seedlings and high yields, and whether sowing can be done on time or not is decided largely by accumulated temperatures before the onset of winter. If sowing is done too early or in years when the autumn is warm, if accumulated temperatures before the onset of winter amount to 700 degrees, the wheat seedlings may grow too vigorously. If, however, sowing is done too late or in years where the autumn is cold, accumulated temperatures before the onset of winter may be less than 100 degrees, and then weak seedlings may result.

An analysis of the long range weather forecast for the time when harvesting sowing and replanting will be done this fall shows a likelihood that total rainfall will be more than in most years, that the rain will be concentrated in the early period, that average monthly temperatures will be slightly lower than normal in September but close to normal in October, and that the first killing frost in most parts of the plain will come toward the end of the second 10 days period or early during the final 10 day period of October.

Analysis of the overall temperature trend shows that this fall will be a usual one, particularly that in wheat growing regions low soil moisture will be favorable. This year the most suitable time for sowing wheat will be about a day earlier than in most areas. In Shijiazhuang and Xingtai prefectures, the most suitable time will be between 24 September and 7 October. Wheat should be sown no earlier than 22 September at the earliest or no later than 14 October at the latest. In Tangshan and Langfang prefectures, the best time for sowing wheat will be between 29 September and 30 October. Sowing should not be done earlier than 17 September at earliest or later than 8 October at the latest. In Cangzhou and Hengshui prefectures, the most suitable time for the sowing of wheat will be between 23 September and 6 October. Planting should not be done any earlier than 21 September at the earliest or any later than 13 October at the latest. In Handan Prefecture, the most suitable time for sowing will be between 26 September and 9 October. Sowing should be no earlier than 23 September at the earliest and no later than 16 October at the latest. In Baoding Prefecture, the most suitable time for sowing will be between September and 3 October. Sowing should be done no earlier than 19 September at the earliest and no later than 10 October at the latest.

BENEFITS OF FURROW SOWING OF WHEAT RECOGNIZED

Shijiazhuang HEBEI RIBAO in Chinese 24 Sep 82 p 1

[Article: "Remarkable Yield Increases From Forrow Sowing of Dryland Wheat in Experiments and Demonstrations Conducted by Hengshui Prefecture Agricultural Research Institute. Opens New Way To Increase Yields on Dryland, Infertile, and Saline-Alkaline Wheatfields. Province Makes It a Major Item for Demonstration and Promotion in Heilonggang Prefecture"]

[Text] Success has been achieved with new techniques for the sowing of wheat in furrows in arid areas that the Hengshui Prefecture Agricultural Institute has summarized, experimented with, demonstrated and promoted. Results of experiments at many sites over a period of 3 years have shown yields from the sowing of wheat in furrows to average 470 jin per mu, a 16.7 percent increase over flat sowing. In low yield wheatfields, the increase in yields was 26.6 percent, and in high yield wheatfields, it was 9.3 percent. During 1982 experiments were conducted at 29 places in the prefecture, increased yields occuring at 28 (at one place yields fell 1.3 percent). High, medium, and low yield wheatfields alike showed increased yields, the average yield increase being 23 percent. In low yield wheatfields, the increase amounted to 35 percent.

In order to develop a new situation in wheat production in Heilonggang Prefecture, to overcome aridity, soil infertility, salinity, freezing, hot dry winds and other natural disasters that occasion unfavorable conditions for wheat production in the prefecture, Hengshui Prefecture diligently summarized traditional experiences in the sowing of wheat in furrows during 1978, and began in 1979 to continue repeated experiments with this traditional experience. It further improved its summarization and study and verified that the sowing of wheat in furrows has overall effectiveness in combating drought and withstanding cold through retention of rain and snow, reduced evaporation, maintenance of soil moisture, avoidance of alkalinity, and improvement in the soil surface microclimate. It benefits wheat growth and development, and yields. Specifically:
1. sprouting rates are high, and a full stand of seedlings can be maintained. Furrow sowing parts the dry soil layer so that the seeds can effectively come in contact with the moist soil below to produce a high sprouting rate. At the Wukaihe Production Brigade in Hengshui County, on a plot of late wheat where soil moisutre was seriously

depleted, water content was less than 10 percent from 0 to 10 centimeters down, and the dry woil layer was 7 centimeters thick. When furrow sowing was done just once, a full stand of seedlings resulted, but the seedling growth rate was only 30 percent from flat sowing, and sprouting was 7 days late. 2. It can promote the strengthening of seedlings before the onset of winter. Because the wheat seedlings within the furrows are well covered and little exposed, and since there is little airflow exchange near the ground, evaporation from the soil is reduced. In addition, precipitation concentrates in the furrows so that marked improvement in soil moisture takes place in the soil from a depth of zero to 10 centimeters. Measurements taken before the onset of winter showed moisture content in the forrows of 14.5 percent, 3.13 percent more than the moisture content of soil where seeds were flat sown. In addition, average air temperature in furrows was between 0.5 and 1 degree higher than in flat sown soil. Consequently, for furrow-sown wheat, root growth and tillering increases by about one-fourth. Leaf surface and weight of dry material increases by one-third, and main stem, and leaves of main stems increase by 0.8 leaves. 3. seedlings are protected for overwintering, and they develop early and grow rapidly in spring. Since furrows are sheltered from the wind and exposed to the sun, direct blasts of cold wind on the seedlings are avoided. In addition, as sides of the furrows slip downward, tillering nodes become buried rather deep, accumulate rain and become filled with sonw, which helps the wheat sprouts overwinter. The winter of 1980 and 1981 had weather that killed large numbers of winter wheat seedlings. The seedlings death rate for flat sown wheat was 24.6 and 27.2 percent respectively, while the seedling death rate for furrow sown wheat was 17.2 and 12.6 percent respectively. Experimental data also show that furrow sown wheat greens up, starts to grown, and joints earlier than flat sown wheat. Fourth, furrow sowing promotes root system development, numbers, and size. Furrow sown wheat has from 597,000 to 1,996,000 more individual roots than flat sown wheat. Because the root system develops well, the wheat's resistance is increased, thereby bringing about an increase in spikes and an increase in grain, prevention of premature degeneration in the late stage, resistance to hot dry winds, and increase in grain weight.

Because furrow sown wheat techniques reduce, to a certain extent, damage from aridity, infertility, alkalinity, overwintering, and hot dry winds, it is able to increase wheat yields in dryland wheat growing areas. In April this year, the Chinese Academy of Agricultural Sciences, organized experts and scientific and technical personnel from the six provinces and municipalities of Hebei, Shandong, Hubei, Shaanxi, Beijing, and Tianjin to hold an on-site meeting for the exchange of experiences at Wukaihe Production Brigade in Hengshui County. Everyone gave full affirmation of the agronomical benefits of furrow sowing and prospects for its spread. They also decided on vigorous experimentation, demonstration, and promotion of furrow sowing in North China's wheat growing areas. The Provincial Wheat Work Conference decided to make it a major topic for demonostration and promotion in the province's Heilonggang Prefecture.

CREDIT GIVEN RESPONSIBILITY SYSTEMS FOR PREFECTURE'S ECONOMIC IMPROVEMENT

Shijiazhuang HEBEI RIBAO in Chinese 21 Sep 82 p 1

[Article by Rural Work Department, Baoding Prefecture CPC Committee: "Agricultural Production Responsibility Systems Have Brought New Vitality to Baoding Prefecture"]

> [Text] Editor's Note: Eighty percent of production teams in Baoding Prefecture have instituted large scale assignment of responsibilities to individual households, and this year the area sown to wheat, though 560,000 mu less than last year, produced 150 million jin more wheat than last year. A comparison of the first half of this year with the same period last year shows output value of commune and brigade enterprises to be 15 percent greater, commune member income from household sideline occupations in the prefecture to be 12 percent greater,and agricultural use of diesel engines and tractors to have increased by 99 and 33 percent respectively.

Since the Third Plenary Session of the 11th Party Central Committee, Baoding Prefecture's production responsibility systems have grown rapidly. Eighty percent of production teams throughout the prefecture have instituted responsibility systems of large scale assignment of responsibilities to individual households, which have brought new vitality to agriculture. This year, despite a 560,000 mu reduction in the area sown to wheat, output increased 150 million jin. Comparison of the first half of this year with the same periods last year shows a 15 percent increase in output value of commune and brigade enterprises, a 12 percent increase in commune member income from household sideline occupations, and an increase in agricultural use of diesel engines, tractors, and water pumps of 99, 33 and 180 percent respectively.

In the process of implementing responsibility systems whereby work responsibilities are assigned individual households, the broad masses of cadres and commune members proceeded from realities, centralizing that which lent itself to centralization and decentralizing that which lent itself to decentralization. They generally instituted the centralization of planting, sowing, and watering, and this not only brought into play the superiority of the collective economy but also reduced intensivity of peasant labor and very greatly changed production conditions. During spring and summer this year, the entire prefecture experienced a drought such as has rarely occured. The water table fell by a general 3 to 6 meters, and cadres and commune members relied on the collective and on the pooled wisdom and efforts of everyone to sink more than 6,000 wells, to dig more than 50,000 indigenous style wells, and to buy more than 8,000 pieces of equipment for raising water. The prefecture expanded its irrigated area by more than 50,000 mu to assure the on-time watering of its large wheat area. This year both the prefecture's yields per unit of area and total output were higher than last year by 8 and 7 percent respectively. Moreover the increases in yields were even. Low yield counties having yields of less than 200 jin per mu fell from last year's seven to four. State purchase quotas were fulfilled with 184 million jin of grain for a 2.2 percent overfulfillment.

Institution of production responsibility systems promoted development of household sideline occupations and commune and brugade enterprises, increased peasant income, and enlivened rural markets. For the first half of this year, workforces engaged in commune and brigade industrial sideline occupations in the prefecture increased by more than 20,000 people over the same period last year, and income increased by more than 10 million yuan. Following assignment of agricultural work responsibility to individual households, a "craze for livestock breeding" occured throughout the prefecture. Statistics from quarters concerned show that as of the end of June this year, the prefecture's hogs numbered 1.73 million for a 5.9 percent increase over the same period last year. Domestic fowl such as chickens, ducks, and geese numbered 15.27 million, a 76 percent increase over the same period last year. Specialized households and key households engaged in the breeding of livestock in the prefecture totaled 13,755. With the development of economic diversification, peasant income increased tremendously. Rural savings accounts for the first half of this year increased by 35 percent over the same period last year. Rural markets were brisk; there was a plentiful supply of goods, and business was good. For the first half of this year, country fair transactions totaled more than 100 million yuan, an 11.5 percent increase over the same period last year.

Production responsibility systems also gave impetus to development of agricultural science and technology. Rural village throughout the prefecture formed a network for promotion of agricultural techniques centering around agricultural science households. These networks gradually linked traditional production experiences to modern science for full play of the inherent potential that the land and the workforce contain to assure increased yields and increased income from crops.

DEVELOPMENT OF PELLITIZING MACHINE FOR SUGARBEET DROSS REPORTED

Beijing RENMIN RIBAO in Chinese 24 Sep 82 p 1

[Article: "Nationally Produced Pellitizing Machine Successfully Manufactured; Sugarbeet Dross Becomes a Treasure. Sugar Refinery With Daily Output of 1,500 Tons Can Pellitize 80 Tons of Dross for Annual Earnings of 2.3 Million Yuan"]

[Text] The Haerbin Oxygen Machine Manufacturing Plant has developed a machine to pellitize sugarbeet dross, which will convert sugarbeet dross that had formerly been thrown away into a treasure.

The pellitizing machine is a piece of equipment that uses the waste (sugarbeet dross) resulting from the processing of sugarbeet raw materials by sugar refineries. Except for a small portion that had formerly been fed to livestock, the large quantity of waste that sugar refineries produced daily had been thrown away for the most part. After a time it rotted and stank, polluted the environment, and endangered human health. A survey has shown that in Heilongjiang Province alone annually such waste amounted to more than 2.7 million tons. If a pellitizing machine were used to compress it into dry pellet residue, it could be easily transported and stored, and it would make an extremely good feed for livestock. Sometimes, some of it might be exported as well. As an export price of 160 yuan per ton of pellitized residue, what with the daily pellitizing of 80 tons of residue by a sugarbeet refinery with a daily output of 1,500 tons of sugar, 2.30 million yuan could be earned annually and economic benefits would be quite impressive.

The Haerbin Oxygen Machine Manufacturing Plant actively served the sugar industry and in less than a year's time successfully developed the Type KL 2 pellitizing machine for the Heilongjiang Sugar Industry Company. Heilongjiang Province's Machinery Bureau and Sugar Industry Company organized 24 units to provide an evaluation. The evaluation team believes that the pellitizing machine developed by this plant is attractive and in good taste, that it operates reliably, that its operation and maintenance are convenient, and that its performance substantially meets design requirements.

China's sugar refineries imported a set of Japanese pelletizing equipment (two pellitizing machines, one cooling machine, and one sifting machine) at a cost of 480,000 yuan. The same set of equipment made by the Haerbin Oxygen Machine Manufacturing Plant has an ex-factory price of 156,000 yuan; furthermore spare parts can be provided promptly, the prices are cheap, and the plant can send people to install and regulate the equipment. Consequently it is readily accepted by customers. As of now the plant has delivered 12 machines, which are in use with very good results in several major sugar refineries in Haerbin, Qiqihar, Jiamusi, and Acheng in Heilong Province.

HENAN

MAJOR EFFORT TO INCREASE WHEAT OUTPUT REPORTED

Beijing RENMIN RIBAO in Chinese 10 Oct 82 p 2

[Article: "Henan Province Fall Wheat Sowing Area Large and Quality Good. Encouraged by Spirit of 12th Party Central Committee, People's Minds Are at East and Their Enthusiasm for Production High"]

[Text] The vast Henan heartland has now entered the extremely busy season of fall sowing. In the major wheat growing areas o Zhoukou, Xinxiang, Luoyang, and Kaifeng, as well as in the rural suburbs of Zhengzhou, the masses of peanants, encouraged by the spirit of the 12th Party Central Committee, have carefully chosen fine varieties of seeds, spread copious quantities of manure, and the area sown to wheat this fall is greater and quality better than in the past.

This year, everywhere in Henan Province a craze for hurried exchange of superior variety seeds has taken place. Eac time seed stations have brought in a shipment of superior variety seeds, peasants have arrived in droves from all over as though going to a fair. Recently the Luoning County Superior Varieties Station brought in more than 500,000 jin of superior variety seeds. No sooner were they inside the station gate than they were snatched up in exchange for other grain until no more remained. "No planting of anything but superior varieties" has become the overwhelming desire of the broad masses of peasants in developing wheat production. Selection of the best from among superior varieties, and careful removal from superior varieties of any seeds that are not superior varieties, has become a conscious action by peasants in most areas to get high wheat yields.

At the same time, this year Henan peasant zeal for collecting manure, composting manure, and buying fertilizer has also been unprecedented. Arriving at a commune or brigade, one sees barnyard manure piled everywhere in front of and behind houses, inside and outside villages, along roads, and at the edges of fields. On some fields that have already been plowed and harrowed for the first time, barnyard manure has been spread with every step and now a dark black layer covers the fields. A peasant who had contracted land said, "When fertilizing used to be done, to tell the truth it was a case of moving soil from one place to another. Last year people still feared that policies might change, so the quality of crude manure was very poor, but this yeear the manure is the real thing." "The government has called for more fertilization to grow more grain. I put down more than 6 cubic meters per mu of crude manure, 100 jin of ammonium carbonate, and 120 jin of phosphate fertilizer as base fertilizer, so there is probably no doubt about harvesting a bumper crop!" A survey done at Zhidian Commune in Chenqiu County showed each household had put down more than 4 cubic meters per mu of crude manure, and between 100 to 120 jin or more of ammonium carbonate and phosphate fertilizer. Actual amount of fertilizer used increased by about one-third over last year. In recent years benefits have been considerable from the use of phosphate fertilizer by numerous people, and phosphate fertilizer has become the means of production in shortest supply everywhere. This year, even though the quantities brought in by the state and purchased by people themselves have been vastly more than in previous years, the scramble to buy phosphate fertilizer can still be seen everywhere.

This year the area sown to wheat in Henan is larger than in any previous year. The peasants say, "Henan is a wheat growing area, so we have to do everything possible to sow more wheat." In Zhoukou Prefecture, for example, wheat has been sown on fields where spring sweet potatoes were to have been grown, and wheat and cotton have been intercropped on the spring cottonfield area. In addition, the 10 besides [beside houses, roads, streams, villages, etc] have been readied and ponds have been filled in for a very great increase in the actual area sown to wheat. This prefecture's planned wheat growing area has been increased to more than 8 million mu this year, an increase by about 500,000 mu over last year. The wheat growing area of other prefectures has also been expanded to varying degrees. In order to get high wheat yields, everywhere in Henan this year attention has been given intensive farming. Peasants have plowed and replowed wheatfields, and harrowed and reharrowed them. Some have required three cultivations and nine rakings. Some plots have been made level and the soil pulverized. In many places, in the process of cultivating and raking, pesticides have been applied against locally occuring insects. This year fertilization has been done differently than in past years as well. Not only has fertilization with nitrogenous, phosphate, and potash fertilizer been required for each plot, but balanced use of the three has also received attention. Formerly not enough attention was given base fertilizer, but this year great attention was devoted to the amount of base fertilizer put down. In Chenqiu County, for example, to make up soil fertility deficiencies and to meet needs for increased yields, this year it was proposed that a "1, 1, 3, 4" per mu average base fertilization be given (with individual variations for field plots in practice), by which was meant 100 jin of ammonium carbonate, 100 jin of phosphate fertilizer, 30 jin of urea, and 4 cubic meters of barnyard manure, both to assure full stands of sturdy seedlings, and to lay a foundation of normal growth of wheat seedlings next year.

FRESHWATER FISHING INDUSTRY RAPIDLY DEVELOPING

Beijing RENMIN RIBAO in Chinese 21 Sep 82 p 2

[Article: "High Speed, Highly Beneficial Development of Hubei's Freshwater Fishing Industry"]

> [Text] Editor's Note: The issues this report raises on good handling of several relationships in development of a freshwater fishing industry can set people to thinking. Facts have shown that all that is needed is a clear guiding idea for good handling of these relationships and implementation of measures to increase output, and then the freshwater fishing industry can develop at high speed for high benefits.

Hubei has been often called the "province of 1,000 lakes." The climate here is temperate, rainfall copious; the land is traversed by streams; and the area is densely covered with lakes and reservoirs. Water surfaces usable for bleeding amount to one-tenth the national amount of inland waterways usable for breeding. It is a major freshwater fishery area in China. Following the 3d Plenum of the 11th Party Central Committee, the province's fishing industry developed very quickly. Last year gross output of aquatic products amounted to more than 300 million jin for a revival of the all-time highest level. Average rate of growth during the past 3 years has been 11.1 percent. Counties in the province having an annual output of more than 5 million jin have increased from 14 before 1978 to last year's 23. The 10 years of turmoil caused damage to the fishing industry, but after 3 years of effort, the long standing fluctuation in output has been brought to an end.

Today, following diligent study and investigation, the provincial aquatic products sector has decided to handle several relationships well, thereby enabling high speed, highly beneficial development of the freshwater fishing industry. These relationships are as follows:

The relationship with state-owned fishing industry and the fishing industry owned by the masses. As a result of "leftist" influence and investment in construction, for a long time numerous comrades have given comparatively more attention to the state-owned fishing industry. Now, while taking firmly in hand development of the state-owned fishing industry, they have shifted the focus to the fishing industry owned by the masses including the breeding of fish by communes and brigades, commune members, and social organizations.

This is because of the following: First, more than 80 percent of the more than 300 million jin of fish produced in the province came from the rearing of fish by the masses. Second, from an investment standpoint, the state must underwrite the state-owned fishing industry in entirety, while the collective fishing industry requires an assistance kind of investment. When commune members and social organizations rear fish, the state is required to provide virtually no money. Third, only through an expansion of commune member rearing of fish can peasants, who comprise more than 80 percent of the population, have fish to eat, and only then can the state-owned fishing industry supply larger amounts of aquatic products to cities, towns, industries, and mines. Fourth, development of the mass fishing industry helps improve the natural environment, accommodates production and the daily life of the masses, and enlivens city and countryside markets. Fifth, development of the mass fishing industry helps stabilize the state-owned fishing industry's proprietary rights over water surfaces, maintains order in production of lake and reservoir areas, and truly achieves increased production, increased incomes, and increased contributions.

Relationship Among Large, Medium Size and Small Water Surfaces. For many years most large water surfaces have lay in a state of disuse or low production. The reason is that large water surfaces have three problems difficult of solution. One is that the administrative system cuts across lines and conflicts exist between fisheries and agriculture, and between the state (owned enterprises) and the masses (operations). Second, fish breeding ponds, the equipment required to pen fish in, and dike locks and stations all require a great investment for construction and equipment. Third production programs in fishery areas are in a shambles. Some comrades say that large water surface production consists of "a figuring of accounts that is gladdening, doing work that is wearing, and trying to raise output that is infuriating." Consequently, intensive raising for high yields on small water surfaces has to be the principal direction of attack, with intensive raising being paramount and use of small water surfaces for intensive raising being paramount. At the same time there can be no relaxation in management and utilization of large water surfaces.

Relationship Between Extensive Rearing and Intensive Rearing. In most places in Hubei Province, an extensive low yield situation has existed right up to the present of "release the fry and watch them grow; catch large and small till there are no more." Average yields for the province's more than 1 million mu of ponds has been only a little more than 100 jin per mu, lower than that of Guangdong and Hunan. About 40 counties in the province have pond surfaces of more than 300,000 mu. In Jingmen and Sui Counties, there are more than 100,000 mu, and potential is very great. In order to raise pond fish yields, it will be necessary, first of all, to change the present breeding of silver carp as the predominant fish so that herbivorous fish varieties with "heads that hang down" will be changed to fish with "big heads." Second is changes in the composition of fish food. Grass has to be grown to rear fish, turning grass into meat. Third is a good job of fish disease prevention and control work; and fourth is companion rearing of fish at separate levels in the water, and rotating catches with releases of fry.

Relationship Between Fish Rearing and Economic Diversification. It is necessary to proceed from water surface realities, setting up fisheries in places suited for fisheries, growing lotus in places suited to the growing of lotus, rearing fish in places suited for rearing, and using varieties suited to particular areas, striving to make the water surface breeding industry and the water surface growing industry thrive at the same time. Some communes and brigades have planted mulberry trees on pond banks and on fields growing feed to combine fisheries with the growing of mulberry. The pond mud fertilizes the mulberry; the mulberry leaves feed silkworms; and the silkworm excrement feeds fish for fairly good economic results. If all the province's several hundred thousand mu of continuous tract fish ponds did this, they would become a very large fishing industry base, silkworm mulberry base, and feed base. In this way, income amounts to several hundred yuan per mu of water surface, or even as much as 1,000 yuan. In addition, water surfaces may be used for development of pearl production.

Relationship Between State Plans and Market Regulation. The Hubei aquatic products sector believes that in studying aquatic products procurement and marketing policies, the basis should be to take the planned economy as the key link with market regulation being supplementary, and that state procurement quotas should be established for state-owned fishery farms, specialized communes and brigades, and commodity fish bases. Following fulfillment of state purchase quotas, production units should be allowed to dispose of surplus fish products in accordance with market management regulations. For communes and brigades, commune members, and social organizations, however, there should be no purchase quotas for the rearing of fish.

Right now Hubei's freshwater fishing industry is in good shape. As of the end of July, fresh fish output for the province was 11.8 percent greater than for the same period last year and purchases increased 27.3 percent. Amounts turned over to the state increased 15.6 percent and exports increased 10.5 percent. The rearing area increased 11.7 percent, and fingerlings released increased 13.9 percent. Especially heartening is that raising of fish by rural commune member households grew from 400,000 households last year to 520,000 households this year, and the breeding area expanded from somewhat more than 140,000 mu to 210,000 mu. In the commodity fish bases located along the Chang Jiang and both banks of the Hanshui, fish growth is heartening. In Honghu and Mianyang Counties, about one-third of the fishbase ponds have yields of 400 jin per mu. Both the state-owned fishing and suburban rearing of fish has developed substantially. Provincial Aquatic Products Bureau deputy director, Ma Jamin [7456 4949 3046] told reporters: "Attainment of the combat goal of an output of 1 billion jin of fresh fish for Hubei by the end of the century is an extremely formidable task; however, so long as guiding ideas are clear and all of the foregoing relationships handled well, policies and programs correct, and measures for increasing output solidly based, Hubei's freshwater fishing industry will certainly be able to develop at high speed and highly beneficially."

INCREASE IN PEASANT SPENDING REPORTED

Beijing RENMIN RIBAO in Chinese 14 Oct 82 p 2

[Article: "Marked Increase in Peasant Purchasing Power in Liaocheng Prefecture. Jump in Sales of Means of Production and Means of Livelihood; Name Brand Goods Even Better Received"]

[Text] Rural markets in Liaocheng Prefecture in Shandong Province are unprecedently busy today. Peasant purchases of means of livelihood and means of production have spurted, and name brand goods are even better received.

Liaocheng Prefecture has been a notorious poverty stricken area in the country where peasant purchasing power has been very low. In recent years, peasant income has risen remarkably. In 1981 gross income from agriculture in the prefecture was more than 1.0 billion yuan and per capita distributions averaged 176 yuan. Commune member savings amounted to more than 160 million yuan, 10.1 times more than in 1978.

Most of the well-heeled peasants put purchases of the means of production in first place. According to statistics from the prefecture's supply and marketing system, total sales of the means of production were 40.7 greater in 1981 than in 1978, an increase of 40.7 percent. This included chemical fertilizer, pesticide devices, and medium and small farm implements, increase in the sale of which was fairly great. Peasant households buying farm machines and large livestock animals were also fairly common. The selection of peasant purchases of the means of production was also improved. With the launching of scientific farming and more careful attention to economic benefits, high nitrogen urea and phosphate fertilizer were in short supply, and highly effective pesticides of low residual toxicity were far from meeting peasant demand. Twelve horsepower tractors, which formerly sold poorly, became "hot items" liked by the peasants.

Last year sales of the means of livelihoodin Liaocheng Prefecture reached more than 640 million yuan or 70 percent of total retail sales of social commodities. Among purchases, high quality durable consumer goods and name brand goods particularly characterized current purchases of the means of livelihood in Liaocheng Prefecture. Beer, bottled wine, canned goods, and such medium and high quality goods, which had formerly found markets only in cities, now sell well in rural villages as well.

YUNCHENG PREFECTURE MAKING PROGRESS TO INSURE BUMPER WHEAT HARVEST

Beijing ZHONGGUO NONGMIN BAO in Chinese 23 Sep 82 p 1

[Article: "Progress Rapid and Quality High in Yuncheng Prefecture Preparations for Fall Sowing, Powered by Spirit of 12th Party Central Committee"]

[Text] Yuncheng Prefecture is one of the principal wheat growing regions of Shanxi Province. Ths year witnessed "three overs" in the growing of 5.4 million mu of wheat as follows: 15.4 percent over last year, 18.9 percent over plan, 10.4 percent over the all-time high. The broad masses faces are wreathed in smiles. Upon hearing again during the 12th party Central Committee a reiteration that responsibility systems would endure without change for a long time, both cadres and commune members are more at ease. Each county further perfected various forms of production responsibility systems making them fit local circumstances more closely. Production teams practicing responsibility systems of "double contracting" [contracting to households both responsibility for fixed output quotas and completion of assigned work tasks] increased from 88.4 percent before the wheat harvest to 95.4 percent.

Inasmuch as the broad masses of people have sufficient zeal and great determination for the winning of a bumper wheat harvest next year, the entire prefecture has laid a fine foundation for a bumper wheat harvest next year. One is that much fertilizer has been made ready. Barnyard manure averages 3.98 cartloads per mu, 0.3 cartloads more than last year. Nitrogenous fertilizer averages 30.1 jin per mu, 9.4 jin more than last year. Phosphate fertilizer averages 24.4 jin per mu, 11.3 jin more than last year. Second is an increase in the deep-plowed area. About 3 million of the 3.68 million mu of the first crop wheatfields have been deeply plowed. This is more than 900,000 mu more than last year. Third is a greater area put in proper farming condition. The wheatfield area that has been carefully leveled amounts to 1.1 million mu, more than double last year's amount. Four is light cultivation and harrowing a larger number of times. Fifth is sufficient quantities of wheat seeds have been prepared and the quantity of select seeds is larger than last year. Throughout the prefecture, 56,280 "science and technology households," "associated households," and "key households," have undergone training to improve their skills so that wheat growing techniques will be spread from one neighbor to another to myriad households. In addition, departments concerned in prefectures and counties have printed large amounts of data about wheat growing techniques, and training classes have been run at every level. Training at the county, commune, and brigade levels in the prefecture has been given more than 520,000 attendees, more than in any other year.

DEVELOPMENT OF DRYLAND CROP AGRICULTURE DISCUSSED

Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 8, 1982 p 2

[Article by Liu Jie [0491 2638] and Guo Jinyu [6758 6855 3768] of the Agricultural Resources and Zoning Institute of the Shanxi Provincial Academy of Agricultural Sciences: "Exploring the Ways to Develop the Agriculture of Dryland Crops"]

[Text] Since ancient times, agriculture in Shanxi has mainly been an agriculture of dryland crops. Since liberation, although the wetland areas have developed greatly, the proportion of dryland-crop agriculture is still absolutely dominant. Bumper harvests or deficient harvests are determined to a large degree by rainfall. When the weather is favorable, agriculture will produce bumper harvests. When severe drought occurs, the output drops. Therefore, how to manage the dryland-crop agriculture has become a strategic problem in increasing agricultural output in Shanxi.

I. The Characteristics of Dryland-Crop Agriculture in Shanxi

There are four types of arid soil conditions in the world: Seasonal aridity of the tropics, tropical semi-aridity, subtropical semi-aridity, mid-latitude aridity and semi-aridity. The arid regions in Shanxi Province belong to the fourth type characterized by the following: Cold and warm seasons are clearly separated. Rainfall in the semi-arid regions is consistent with the rainfall in the warm seasons, but variation between years and between seasons is great. The standard annual rainfall lies between a lower limit of above 250 millimeters and an upper limit of 450 to 600 millimeters. The actually effective rainfall in Shanxi (natural rainfall minus runoff) is generally between 450 and 550 millimeters in the southeastern part and in some mountainous regions in the province and between 400 and 480 millimeters in other central and southern regions in the Province. It is between 350 and 400 millimeters in the northern regions. Generally, the annual supply rate of water (effective rainfall/total consumption of water) can at various times reach 55 percent and 90 percent. The water supply rate in river basins and low hilly regions is the porrest, while it is higher in the high mountain regions and the southeastern regions. Shanxi is a rather typical arid and semi-arid region.

Drought in Shanxi occurs most frequently in the spring. This has been the characteristic of drought in Shanxi for a long period. The so-called "9 years of drought out of every 10 years" mostly refers to the occurrence of spring drought. Since 1972, spring drought has caused damage to varying degrees almost every year. But this type of spring drought does not greatly affect the yield of autumn crops as long as moisture is conserved in winter and spring, seeds can be sown and the seedlings are managed well.

Summer drought generally causes lighter damage. From the last 10 days of May to the middle 10 days of June, a period when the growth of seedlings of autumn-sown crops is restrained, damage by drought is generally not large. Where summer drought occurs, there is the saying that "money cannot buy May drought, but when overcast weather continues in June, there will be alot to eat". This notwithstanding, however, if summer drought persists for a long time, it will also cause serious damage, therefore there is the saying that "summer drought reduces output by half." In Yuncheng and Linfen Basin in the south, summer drought occurs more frequently, while in Taiyuan, Xinding Basin and in some hilly regions of constant aridity, drought occurs less frequently.

Summer drought mostly occurs in the central and southern parts of Shanxi, and the frequency is higher especially in the southern regions. From 1972 to 1979, the southern regions all suffered from severe summer drought, affecting the heading of summer sown crops and the forming of cotton bolls. The local people call this the "choking drought." The frequency of autumn drought is smaller. In recent years, it has mainly affected the sowing of wheat and the development of wheat seedlings in the south and but it has not affected other crops much.

II. The Cause of Low Yields of Dryland Crops

At present, the agricultural yeild of dryland crops is not high. There are mainly three reasons:

1. The land is infertile and there are fewer fertilizers. As a result, there is limited utilization of rain water. The low agricultural yield in drylands in ordinary years seems to be due to a lack of water, but actually it is due to a lack of fertilizers. The fundamental environmental factors for agricultural production are the five indispe6sable elements of light, heat, water, fertilizer and air. None of the five can be missing and one cannot replace the other. Whether the yield is high or low is determined by the lowest determining elements. The three elements of light, heat and air above, under present conditions of agricultural production, can satisfy the needs for producing a thousand jin or several thousand jin. But only the two elements of water and fertilizers are the determining factors in agricultural production. According to experiments and the output of advanced commune brigades, the amount of rain in an ordinary year is 400 to 500 millimeters, sufficient to produce 400 to 500 jin of output over large areas. But in reality, why have we been unable to reach this level? It is mainly because of insufficient

fertilizers and the deficiency of nutrients in the soil. According to the results of general surveys of the soil, only 25 percent of the total area of cultivated land throughout the province consist of soil with an organic content of over 1 percent, 40 percent of the land consists of soil with an organic content of over 0.5 percent, and the remaining 1/3 of the area consists of soil with an organic content below 0.5 percent. According to the results of general soil surveys conducted in the southeastern part of Shanxi, the nitrogen content of each mu of first grade soil is 10.1 jin, the phosphorus content is 5.1 jin. The nitrogen content in second grade soil is 8.7 jin, the phosphorus content is 2.7 jin. The nitrogen content in third grade soil is 7.7 jin and the phoshorus content is 2.5 jin. The deficiency of nitrogenous and phosphorous fertilizers is the determining factor here. Especially in dryland crop agriculture, phosphorous fertilizer is even more so, the main determining factor. Therefore, the fundamental solution in dryland crop agriculture is first to cultivate the fertility of the land, increase the content of organic substances and nitrogen and phosphorus in the soil and correspondingly use fertilizer to modify water and use water and fertilizer complementarily in cultivation.

2. Planting management is careless and the only available amount of rainfall is wasted. The high output experience of the masses over many years is "three tilling, six raking, nine hoeing and drilling." There is also the saying "one plow for wheat harvests and one hoe for autumn harvests." The reason that the output of many communes and brigades is low is closely related to a lack of "three tilling, six raking, and nine hoeing and drilling experience." At some places, the fields are only worked twice a year or three times a year, i.e.: Ploughing and sowing in spring and harvesting in autumn. Some places do better; adding a mid-tilling in between the spring sowing and autumn harvesting. A large amount of water is lost because the fields could not be tilled deeply to store water and water evaporates because the fields could not be raked. Weeds grow uniformly because mid-tilling could not be done in time, causing most of the several hundred millimeters of rain that have already fallen on the cultivated land to evaporate from the empty fields and from between plants.

3. Serious soil erosion carried away large amounts of water and soil fertility. Over 80 percent of the regions of dryland crops in Shanxi are mountainous. In most places, soil erosion is serious. This is the direct cause of soil infertility and aridity. Soil erosion caused serious erosion of the ground surface, soil fertility dropped, and the ability of the soil to store and retain water and moisture dropped. According to measurements made by the Shanxi Provincial Water Conservancy Institute, each ton of soil of the 0 to 15-centimeter soil ayer on slopelands in western Shanxi contains 0.346 kilogram of whole nitrogen, 0.668 kilogram of whole phosphorus and 16.6 kilograms of whole potassium. The amount of fertilizers in the soil lost in soil erosion in western Shanxi, if calculated in terms of chemical fertilizers, was equivalent to 480,000 tons of ammonium sulphide, 2152,000 tons of calcium superphosphate, 12,095,000 tons of potassium sulphate. This is an important reason why the soil in the loess hilly regions is infertile, its ability to store water is poor and the yield is low.

III. Important Ways to Increase Agricultural Yield of Dryland Crops

Generally speaking, our nation's agriculture of dryland crops has three major characteristics: One is organic agriculture, the second is highly refined tilling and planting, the third is man-made agriculture consisting mainly of terrace fields and farmland encircled by ditches. These three aspects have contributed greatly to world agriculture. Future development of the agriculture of dryland crops can be further improved based on these three foundations and by combining the advanced techniques of other nations of the world to open up a way for agricultural development suitable to our nation's actual situation.

1. We must open a way that combines organic agriculture and inorganic agriculture. "One water buffalo equals half an acre of farmland" has been our typical road in organic agriculture for thousands of years. The draft ox has been the main driving force in agriculture. Human and animal excrement and straws have been the source of fertilizers. The cycle of bioenergy will never be exhausted. The more it is used, the more it expands. To develop animal husbandry and improve soil fertility, southern Shanxi which is the main cotton and wheat producing region, has implemented the rotation planting system combining alfalfa, peas and cotton and wheat. This has enabled superior species of the large water buffalo to develop in southern Shanxi and also guaranteed the continued increase in soil fertility. In western Shanxi and northwestern Shanxi where there are fewer people and more land, the rotation planting system of pease flat beans and food grains and oil bearing crops has been implemented according to plans. Central Shanxi and southeastern Shanxi have widely used the system of interplanting and rotation planting of graminaceous crops and leguminaceous crops. This has served a good function in improving soil fertility and increasing the nutrients and organic substances in the soil.

The practice of combining agriculture and animal husbandry, the reverse cropping system of rotation planting and interplanting of leguminous grazing grasses and graminaceous crops, soaking of straw and returning it to the fields have constituted our traditional organic agriculture. As our nation's industry develops, petroleum-based agriculture, consisting mainly of the tractor and chemical fertilizers, has played a huge role in the agricultural system. The yield per unit area in the production of food grains in Shanxi Province has improved as the use of chemical fertilizers increased, and this has correspondingly increased the amount of straw and roots by the same percentage. After the straw was returned to the fields directly or indirectly, it again stimulated the increase of organic substances in the soil and increased the various effective nutrients in the soil. Therefore, we should follow the path of "using the organic to guarantee the inorganic, using the inorganic to stimulate the organic" in improving fertility. This means, we must follow the path of combining organic agriculture and inorganic agriculture. Some problems still exist in the application of chemical fertilizers at present. For example, some high yielding communes and brigades apply too much chemical fertilizer and this greatly increases production costs. Certain commune brigades neglect the accumulation and application of farm manure. The proportion of nitrogen and phosphorus is imbalanced. Thereare also problems with improper storage, management and utilization. Applying less chemical fertilizer or none at all will not solve these problems. We must find a proportional relationship between carbon and nitrogen, for the application of nitrogen, phosphorus and potassium, and between organic nitrogen and inorganic nitrogen. Only when proportionally balanced fertilizers and apples, can we avoid destroying soil fertility due to excessive application of nitrogen fertilizers. At present, an important problem in organic fertilizers is to quickly solve the problem of fuel in farm villages. Shanxi has the richest coal resources. Over 70 percent of the region produces coal. Therefore, exchanging coal for straw and returning straw to the fields directly and indirectly to improve soil fertility, and increase the output of food grains and other agricultural crops are more economical than using coal directly to exchange for agricultural products. In addition, appropriate development of alfalfa in southern Shanxi and popularizing alfalfa, sweet clover, false indigo and sedge and such green manure crops by communes and brigades in a big way in western Shanxi and northwestern Shanxi, where there is more land, and fewer people and where soil erosion is serious, can helpt to reduce the loss of water, develop animal husbandry, improve soil fertility and solve the problem of fuel.

2. We should follow the road of combining fine traditional tilling and cropping technique and modern tilling and cropping technique. Traditional cropping in dryland crop agriculture is characterized by the maximum utilization of natural rainfall. The method of "three tilling, six raking, nine hoeing and drilling" is the typical experience of fine tilling and cropping in dryland. We should organically combine the traditional cropping and modern cropping techniques to create new ways to increase output of our nation's dryland crop agriculture. The key is to uniformly regulate the whole year's rainfall. Annual rainfall in the dryland crop regions in Shanxi is generally between 400 and 600 millimeters, and 70 percent of the rainfall is concentrated in the three months of July, August and September. In spring when water is needed, there is a lack of water. In summer, there is frequently too much rain water. This forms the special situation of spring drought and summer waterlogging. To uniformly adjust the whole year's rainfall, the only effective method is to store all the rain water. The methods of storing rain water are as follows: One way is to build reservoirs to store surplus rain water during the year and then use it when needed. Although this method is good, we cannot fundamentally solve the problem because of the limitations of topography and funds. The other method is to utilize traditional cropping techniques to establish a "cropping layer reservoir." The so-called cropping layer reservoir involves deep ploughing and shallow ploughing in summer and autumn, preserving and preserving moisture in spring and autumn loosen the soil structure of the cropping layer and creating advantageous conditions for storing rain water. During winter and spring when there is less rain, the fields should be raked many times to reduce evaporation of water. During the period from the planting of wheat in autumn to sowing in spring, the fields should be heavily packed in order to bring out the moisture from the deep layers to the sowing layer so to ensure that the seeds will germinate and the root will grow. This is what is commonly called "using summer water in autumn" and "using autumn water in spring." The wheat fields of Dongguanzhuang Brigade in Wensi County were first deeply tilled in summer. After 7 August; the fields should be harrowed aso as to absorb as much summer rain water as possible. The new cropping method of "four early three more" should be used. That is, clean stubbles early, deep ploughing early, fine plowing early, and harrow the soil early, more light plowing, more fine plowing, and more light harrowing of

the fields so that every drop of rain water is kept in the fields, the soil is loose inside and not cracked outside, the surface soil does not have cracks, evaporation is prevented, and the top part is loose and the bottom part is solid without clods. In 1975, that brigade contrasted the new and old tilling methods. The amount of water stored in the soil layer between 0 and 200 millimeters after using the new tilling method and before sowing wheat was 408.8 millimeters, more than that using the old tilling method by 61.6 millimeters. Jinzhuang Brigade in Huguan County used autumn tilling combined with the application of fertilizers and the tilling technique of harrowing the field more times in early spring. The water content in the tilled layer in spring was 3 percent more than the water content in the soil fertilized and tilled in spring. In most years, this could guarantee timely sowing and the preservation of full seedlings.

On the basis of traditional fine tilling and cropping, we must also actively introduce and test the advanced techniques of other nations, such as the use of weeders, the tilling less method, and the method of planting without tilling. These have produced good results after testing in certain regions. Very good results were realized by using ground coverings in planting cotton. Agricultural production using factory-produced large plastic tents will create new conditions for intensive agricultural production.

3. We should follow the road that combines engineering management and biological management. Of the total area of Shanxi, 80.3 percent consists of mountainous and hilly regions. Most of the nearly 60,000,000 mu of cultivated land is hilly mountain land. To guarantee the yield of slopeland in mountain regions, our ancestor created horizontal terrace fields on slopeland and built embankments in trenches and valleys to create land. Such techniques have been proven by history to be successful. The building of terrace fields and land encircled by embankments in trenches to create three-dimensional basic farmland is the fundamental way to develop dryland crop agriculture in mountain regions. It can also be considered a major invention by our ancestors in agricultural production.

To fundamentally solve soil erosion in mountain regions and change the ecological environment, it is not enough to rely on building embankments, preparing land, building terraced fields. We must carry out biological control based on engineering control, return slopeland over 15 degrees in inclination for forestation and grazing, and change the present vicious cycle into a beneficial cycle. Shanxi Province has found effective ways in water and soil conservation over the past 30 years. The main experience is the insistance on comprehensive dredging of small river basins and taking small river basins as the unit in water and soil conservation. The present area is amall. We must not expand outside the commune area. Such work should be carried out by brigades from top to bottom so that biological and engineering measures can be combined. We should plant forests and grass on precipitous slopes and mountain tops, and build terrace fields at the foot of mountains and on gentle slopes below the forests and grassland. Work should be done by contract. The state can provide appripriate investment. We should insist on centralized and continuous management. Then, we will produce definite results. This is an effective method of water and soil conservation at present that requires little investment and that will produce quick benefits.

TITLE: "Preliminary Results of General Soil Survey of Suburbs of Shanghai"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 1-3

ABSTRACT: Based upon The Document No 111 (1979) of the State Council, the second general soil suvey of Shanghai began to be carried out in the autumn of 1979 with Chengdong Commune of Qingpu County as the test point. The Institute of Soil and Fertilizer of the Municipal Academy of Agricultural Sciences, the Soil and Fertilizer Station of the municipal Bureau of Agriculture, Shanghai Academy of Agriculture, municipal Bureau of Water Conservancy, etc. participated in the work, which lasted nearly 80 days. This paper is a brief report of the comprehensive results of the survey of the test point. Chengdong Commune used to be lake-bed low-lying lands. After silting, developing, and cultivating, the soil has matured from the marsh soil origin into low paddy soil of poor drainage. Due to the constant anaerobic reduction state, the residues of aquatic plants are only partially decomposed and utilized by microbes to cause gigantic accumulation of humus. The organic matter content is at 4-5 percent and whole nitrogen above 0.2 percent. Below the topsoil, there is a layer of muck soil or peat. Further below, there is a layer of gley, affected by

[continuation of SHANGHAI NONGYE KEJI No 5, 1982 pp 1-3]

prolonged soaking in the ground water. Although it has long been believed that the soil parent material is entirely limnetic facies, this survey revealed some cross sedimentation of fluvial, limnetic, and marine parent materials. The survey revealed that 3.2 percent of the area of the commune have a ground water table less than 50 cm, 0.8 percent at 50-80 cm, 31.8 percent at 80-100 cm, and 14 percent at 100-120 cm. Since the liberation, efforts have been given to constructing water conservancy structures and the commune is basically protected from flood damages, but there remain various degrees of water-logging damages. At present, about 34 percent of the soils of the commune are severely water-logged and draining is urgently needed to lower the ground water table of these soils. These and other findings of the survey are reported.

TITLE: "Paddy Soil Clay Minerals in the Region of Shanghai"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 4-6

ABSTRACT: For the purpose of understanding the mineral composition, distribution, and physical-chemical properties of the clay granules of soil in order to study soil formation, and identify the soil type and fertility, x-ray diffraction, electromicroscopic photography, and chemical analysis techniques were adopted to observe samples taken from 6 typical profiles of suburbs of Shanghai. Results indicate that in the paddy soil clay minerals, the SiO_2 content is high, at about 44.46-48.32 percent. The Al_2O_3 content is between 22.15 and 24.02 percent. On the profile and in the lower layer, the range of variation is insignificant. The Fe_2O_3 content varies at 8.9-10.74 percent. The positive ion exchange is between 33.30 and 42.20me/100g. The silicon-aluminum rate is 3.2-3.5; the silicon -iron-aluminum rate is 2.51 - 2.84; the whole potassium (K_2O) is 2.82-3.17 percent. The relationship between the clay mineral composition and soil nutrients is discussed. The x-ray diffraction spectrograms of the soil clay minerals of the samples taken from the 6 profiles are reproduced in the paper.

TITLE: "Preliminary Report of Experimental Cultivation of Early-ripening Wheat 7630"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 16-17

ABSTRACT: The 7630 is an early-ripening wheat, bred out by Zhenjiang Prefecture Institute of Agricultural Sciences, Jiangsu Province. It was introduced to Shanghai County Institute of Agricultural Sciences for trial cultivation in 1979 and a yield of 724.8 jin/mu was obtained. It was rated No 4 of the 10 breeds participating in the experiment. In 1980, from 1.77 mu of intercropped spring soybean and small-row seeded wheat (35 percent wheat) 546 jin of wheat was harvested. The results of all test points show yield increases of 3-18 percent above Yangmai No 3. The growth and development characteristics, the utilization values, and the essential points of cultivation technique of the 7630 are discussed.

TITLE: "Classification and Utilization of Climatic Resource of Shanghai Favorable for Triple-crop Grain System"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 27-29

ABSTRACT: When 3 crops of grains are cultivated in a year in the suburbs of Shanghai, the yield is often not stable due to the variation of the weather condition from year to year. The major problem is the low temperature damage to late rice in the autumn. This paper studies the heat energy resources of the region of Shanghai and divides the region in accordance with the distribution of >10°C cumulative temperature during the growth and development period of the late rica crop. On the basis of the classification, the paper concludes that the heat energy condition of Chongming Island is too poor for a triple-crop system. The southern parts of the 2 counties of Jinshan and Fengxian may become the chief area of a triple-crop system. The heat condition of the area of Jiading, Qingpu, and Songjiang can only allow a mixed system of dual and triple crops while Chuansha, Nanwei, and the eastern part of Shanghai County may cultivate 3 crops a year with a grain and cotton rotation system to adjust the seasons.

TITLE: "A Study on Improving the Lean Meat Rate of Pigs"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 31, 30

ABSTRACT: With the development of the national economy and the improvement of the standard of living of the people, the consumers have begun to prefer lean meat and stock of unsold fat pork has begun to accumulate. In Hong Kong, lean pork is selling at about 13.22 HK yuan/jin while fat pork is only about 0.66 HK yuan/jin. Even at the price difference of 20-fold, fat pork still does not sell. In 1980-81, an experiment was carried out jointly by Shanghai Food Export Company, Huacao Breeding Farm of Shanghai County, et al to produce lean porkers through hybridization of 183 pigs. Comparing 5 groupings, hybrids of Shanghai White Pig x Duleke Pig appear to be the best, producing 30.60 percent lean meat in the legs and 60.71 percent lean meat in the body (average of 39 hybrids.) The best mixture of feed and the best feeding method to produce a high lean meat rate are also studied and reported.

TITLE: "Preliminary Report of Experiment With Cultivating Wheat in Rice Paddy Without Plowing"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 pp 37-38

ABSTRACT: Jiading County has a high crop-repeating index and intense conflict of seasons, especially in years of frequent rains when plowing and planting of wheat must all be performed in soggy fields. If the weather is dry, the soil may easily become too tight for the growth of wheat seedlings. This is the main reason for low wheat yield in the county. In 1981-82, the authors experimented with cultivating wheat in rice paddies without plowing. More than 10 experimental points were established in several communes, totaling 15 mu. Three methods were tried: (1) Seeding wheat between rows of rice 10-15 days before the rice harvest; (2) Broadcasting wheat seeds after the rice harvest; (3) Seeding in rows of 2 cun with 5-7 cun in between the wheat rows. Plowed paddies are used for control. Results indicate that on the average (90 percent of the test points) without plowing, the yield of wheat is 4-14 percent higher. The yield is 2.7 percent lower than the control in one test point only. In 1982, the experiment was enlarged to 3,000 mu. The average yield of 50 mu in Zhuxiao Brigade No 9 averaged 775 jin/mu, 114 jin/mu higher than that of the control.

TITLE: "Selection Breeding of the Early Ripening 7750 System of Rape"

SOURCE: Shanghai SHANGHAI NONGYE KEJI [SHANGHAI AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 5 Oct 82 p 38

ABSTRACT: Experimental hybridization of the kohl-rabi type rape and the white cabbage type Nanhui native rape began in 1975 to select and breed out a new system of early ripening rape 7750. After 2 summers of propagation, beginning in 1978, its yield began to be compared with Shengli and 7055 for 3 years. The yield of 7750 is thus determined to be 339.1 jin/mu, 34.7 percent higher than Shengli and 22.4 percent higher than 7055. The 7750 has become the farm breed in Nanhui County since 1979. In regular production, its yield has generally been about 300 jin/mu; may be as high as 350 jin/mu in some high yield fields. Its cultivation technique is introduced.

SOURCE: Beijing NONGYE JIXIE [FARM MACHINERY] in Chinese No 9, Sep 82 pp 12-13

ABSTRACT: For the purpose of lightening labor intensity and improving productivity, the Hanchuan County Institute of Agricultural Machinery began in 1979 to try to make a cotton uprooting machine. Several prototypes have been made, and on the basis of these, the small Hanchuan 4B-141 was produced as the finalized model. It is to be used with a 3 hp walking tractor. Test operations have proved that it can pull up cotton stubble successfully and stack these stumps into a pile at a work efficiency of 2.5-3.1 mu/hr, 7-9 times higher than manual pulling. It was tried last year by Yongfeng Brigade and won the approval of the masses. The cost of uprooting the cotton stubble using this machine is 0.23 yuan/mu, 0.40 yuan less than using manual labor. The structural and work theory and the major technical parameters of this uprooter are given in the paper and illustrated with several drawings.

TITLE: "The Exploitation of Tropical Rainforests in Relation to Soil and Water Conservation in Southern Yunnan"

SOURCE: Beijing LINYE KEXUE [SCIENTIA SILVAE SINICAE] in Chinese No 3, Aug 82 pp 245-257

TEXT OF ENGLISH ABSTRACT: In order to study the laws of soil and water loss of the tropical rainforest and the exploitation and utilization of its land, we carried out a field-plot experiment of water loss and soil erosion in southern Yunnan during the six years from 1962 to 1967. The results of the study are summarized as follows:
1. The seasonal variation of soil and water loss in southern Yunnan is very obvious. It may be divided into three different periods based on soil and water loss over the six-year period.
(1) The period of slight soil and water loss in the hot and dry season (February to May).
(2) The period of severe soil and water loss in the rainy season (June to August).

[Continuation of LINYE KEXUE No 3, Aug 82 pp 245-257]

(3) The period of slight soil and water loss in the cold and cool season (September to January of the next year).
2. The general law is that the runoff, the soil erosion and the runoff coefficient increase with every increase of rain capacity and rainfall intensity in this region.
3. In different utilizations, the soil and water loss of the rubber-tea community is 22.3 percent and 29.7 percent lower than that of a pure rubber plantation, and 95.7 percent and 93.9 percent lower than that of farm crops. Therefore, transforming farmland into rubber-tea community or economic forest land of two stories is a better way of utilizing tropical mountainous areas rationally and decreasing the loss of soil and water.
4. The results of the study still show that the loss of soil and water on the farmland of shifting cultivation is the most serious. It is 778.3 times and 34.5 times that of the tropical rainforest, and 6.6 times and 5.7 times that of the bench terrace, respectively. In order to restore the function of the tropical rainforest ecosystem and prevent the loss of soil and water on farmland in this region, we must safeguard the tropical rainforest against deforestation. We must change the slope land to contoured terrace, and reform step by step the cropping system of shifting cultivation into that of rational rotation of crops. These are efficient measures for raising soil fertility, keeping water and soil, fixing farmland and obtaining high yield of crops.

TITLE: "Research on Large Area High and Stable Yield Cultivation Technique for Grains and Beans in the Central Parts of Liaoning Province"

SOURCE: Dalian LIAONING NONGYE KEXUE [LIAONING AGRICULTURAL SCIENCES] in Chinese No 5, 15 Oct 82 pp 7-10

ABSTRACT: Central Liaoning is one of the major bases of commercial grains in the Northeast. In the past decade, due to overemphasis of grain production, the corn acreage has been consistently enlarged at the expense of gaoliang and soybean and the improper coordination of organic and inorganic fertilizers has resulted in reduction of soil fertility and worsening of agro-ecology. According to tests taken in 1979, the soil organic matter content has dropped from the 1.39 percent of 1975 to 1.25 percent, a rate of reduction of 0.035 percent per year. Incidences of head smut have been 10-30 percent in the last several years. For these reasons, a research project was carried out by the institute in 3 production brigades of Haicheng County to experiment with the following items: (1) To change horizonal seeding to mound seeding to improve drought, flood, lodging, and wind resistance of corn; (2) To change breeds of corn and soybean for better yielding and other manifestations; (3) To increase manure, farm fertilizer, and phosphate applications; (4) Reasonable density to improve utilization of photo-energy and land; (5) Green manure cropping to nurture soil fertility. Yield increase results in the 3 brigades in 1980 and 81 are reported.

TITLE: "On Improving the Fertilizer Application System for Rice---Replacing the 'Top Heavy' Application Method With late Stage Follow-up Method"

SOURCE: Dalian LIAONING NONGYE KEXUE [LIAONING AGRICULTURAL SCIENCES] in Chinese No 5, 15 Oct 82 pp 14-18

ABSTRACT: The top heavy method of fertilizer application had been in use in the rice paddies of Liaoning until the early 70's. Under the condition of small amount of nitrogen application, this was a method of applying mainly tillering fertilizer to guarantee the yield increase effect. In recent years, the quantity of nitrogen fertilizer has reached a high level and with the top heavy method, serious lodging has occurred. In years of low temperature, the growth and development period became too long as well. Studies carried out by the Institute of Rice Crops and the Institute of Soil and Fertilizer demonstrated that the old method had to be changed. After 2-3 years of testing, a new method of applying nitrogen fertilizer as follow-ups in different stages was adopted to replace the old and yield increase results of 7-10 percent have been obtained. The new method is offered in the paper for the reference of rice growing regions of the Northeast, the Southern Plains, as well as the cold rice growing regions of the North.

TITLE: "An Analysis of Trend of Annual Precipitation Distribution in Yunnan Province"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 8, 10 Aug 82
pp 12-14

ABSTRACT: Many studies have been carried out on the relationship between the annual total rainfall R (one of the most important climatic parameters) and various geographical factors, but it remains difficult to provide a precise and objective simulation of the spatial structure of R. The difficulty is due to the fact that R is a very complex function, determined not only by the geographical location $V(\lambda, \varphi)$ of the observation point but also by the extremely variable factors of the terrain. Of these, the elevation H is easily directly expressed by related parameters and its relationship is often reported by various areas in recent years. Others, such as the direction and the grade of the slope, its openness etc. do not yet have suitable indices. For a comprehensive reflection of their quantitative action on rainfall, the function C is abstractly used in the paper to represent the terrain. For the purpose of finding some geographical reasons for the annual rainfall distribution in the 330,000 km^2 of area of Yunnan Province, this paper proceeds with some rough mathematical analysis of the spatial structure of distribution of the annual rainfall in the province. The data of the 130+ weather stations in the province are used in the analysis.

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 145-148

TEXT OF ENGLISH ABSTRACT: Different hosts, including nine cultivars belonging to three species of *Gossypium* (*G. himsutum*, *G. barbadens*, *G. arboreum*) were used for identifying the physiological form of *Verticillium dahliae* Kleb. Ten isolates of cotton Verticillium wilt fungus collected from eight provinces were identified and classified into three forms. Form I was highly pathogenic to three species of *Gossypium*, mainly including the "Jin Yang" strains of Shanxi Province. Form II was less pathogenic to all tested hosts. This form included mainly the "He Tian" and "Che Pai Zi" strains of the Xinjiang Uyghur Autonomous Region. The pathogenicity of Form III was between that of Form I and Form II. This form mainly included the strains of eight other counties of six provinces.

TITLE: "Studies on Resistance of Sweet Potato Varieties to Bacterial Wilt"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 149-152

TEXT OF ENGLISH ABSTRACT: From 1977 to 1981 more than 500 sweet potato varieties from domestic sources and abroad were tested in some severely epidemical regions of bacterial wilt in Fujian for determining their resistance. The results showed that none of them was immune, but there was considerable variation among their disease incidence. Of these varieties, 17 were highly resistant (disease incidence 0.1 ~ 10 percent and its index 1 ~ 5), and 88 varieties were moderately resistant (disease incidence less than 11 ~ 39 percent and its index 6 ~ 20).

According to the recorded data in recent years from many epidemical regions, it was also proved that the depression of resistance of these varieties occurred after continuous planting for 2 ~ 3 years, and it was variable among different varieties. Therefore, in order to prevent the bacterial wilt of the sweet potato, it is necessary to adopt some measures, such as changing the variety annually,

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 149-152]

continuous selecting of highly resistant varieties, planting new resistant varieties, etc.

TITLE: "Studies on Stunt Mosaic Disease of Spinach"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 153-156

TEXT OF ENGLISH ABSTRACT: A spinach stunt mosaic virus was isolated in the spring of 1981 in a spinach field on the outskirts of Beijing. The spinach infected with this virus appeared dark green with yellow mosaic. The leaves were crinkled and malformed, and the plants were severely stunted.

The host range has been tested by sap inoculation. The virus can infect 19 species of plants, including the families Leguminosae, Solanacea, Chenopodiacea, etc. It is transmissible by the aphid (*Myzus perciae*) in a non-persistent manner. The thermal inactivation point is 70°C, dilution end point is 10^{-4}~10^{-5} and longevity in vitro is three days.

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 153-156]

The virus was purified from *Chenopodium quinoa* or *Gomphrena globosa* by means of chloroform clarification, 10 percent PEG-6000 precipitation and two cycles of differential centrifugation. Electron microscopy revealed that the isometric virus particles were 24-25 nm in diameter. The examination of the sedimentation pattern of this virus has given three S values--57S, 94S and 113S. The antiserum titer prepared for this virus is 1:512.

From the data obtained here a tentative conclusion has been made--that the agent of spinach stunt mosaic disease is a strain of broad bean wilt virus.

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 173-178

TEXT OF ENGLISH ABSTRACT: Based on the study of the distribution pattern of the oriental armyworm population, the sampling technique, theoretical sampling numbers and sequential sampling were studied.

1. Comparing the degree of accuracy of several simple random samplings, we consider the chessboard sampling method to be the best one in the investigation of the egg stage, while the parallel-line sampling method can be applied in the investigation of the larval and pupal stages.

2. By calculation, the theoretical sampling numbers of the different developmental stages of the oriental armyworm were defined, and the relation between the theoretical sampling number and relative variance was analyzed.

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 173-178]

3. Using the sequential sampling method, the chemical control standard of the oriental armyworm population in the larval stage in the field was tested. To analyze the larval quantities by means of sequential sampling, the following equations were used:

$$\begin{cases} d_0 = 3.84n - 40.738 \\ d_1 = 3.84n + 40.738 \end{cases}$$

A practical table of determination for field use was made. A calculative character curve and average sampling number curve were given.

ORG: Scientific Research Coordinated Group for Planthoppers of Sichuan, Yunnan and Guizhou Provinces

TITLE: "Migration and Occurrence of White-backed Planthoppers and Brown Planthoppers in Southwest China"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 179-186

TEXT OF ENGLISH ABSTRACT: In southwest China, migration and occurrence of white-backed planthoppers (*Sogatella furcifera* Horvath) and brown planthoppers (*Nilaparvata lugene* Stal) have different features from those in the eastern part of China as a result of the combined effect of different geographic location, topography, climate, cultural system, etc.

The planthoppers immigrated abundantly into the southeastern part of Guizhou Province at an earlier season, with the white-backed planthoppers being the predominant species. In Yunnan Province, immigration appeared first in the southern part and then in the north, and the predominant species was the brown planthopper, followed by the white-backed planthoppers. In Sichuan Province, immigration appeared first in the eastern part and then in the west. The immigratory paths of that generation causing major damage were varied, and the

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 179-186]

migrations of short and middle distances occurred frequently in the summer. Therefore, there were two major damage periods on middle rice during some years.

As for characteristics of occurrence, in normal years planthoppers usually do more serious damage in the eastern and southern parts of the above three provinces than in the western and northern parts. The nearest planthopper populations were the principle sources of emigration doing harm to middle and late rice. It has been found that the planthopper could be checked by various kinds of natural enemies.

TITLE: "Influence of Various Food Plants on the Growth and Fecundity of *Agrotis segetum*"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 187-192

TEXT OF ENGLISH ABSTRACT: Various food plants were tested with the larvae and moths of *Agrotis segetum* (Schiff.) to see their influence on the number of eggs laid. The results show that when larvae fed on leaves of Chinese cabbage, cotton, and corn, along with some wild herbs, the moths emerging laid more eggs and lived longer than did those emerging from the larvae fed on other plants. The larval stage of those fed on *Chenopodium* spp. was much shorter than that of those fed on *Abutilon* spp., and the percentage of mortality was also lower. Moreover, body weights of the pupae whose larvae fed on Chinese cabbage or *Chenopodium* were heavier than those from larvae which fed on potato.

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 187-192]

Results showed that the moths laid more eggs (1.99 ~ 14.06 times) when feeding on honey and sugar or nectar of *Aster* or *Helianthus* flowers than did those living on Chinese cabbage or alfalfa flowers or water alone.

It seems that supplementary diet taken at the adult stage has a more important effect on fecundity than the quality of foodstuff taken at the larval stage.

TEXT OF ENGLISH ABSTRACT: Bioassay of the isolated S01-43 nuclear polyhedrosis virus (SEV) was conducted on early third-instar larvae of *H. armigera* which were individually reared on an artificial diet contaminated with the virus. The regression equation between dosage and mortality was $y = 3.3387 + 0.484x$. The LD_{50} value and 95 percent fiducial limits were 2707 PIB and 1134 ~ 6455 PIB/g of diet, respectively. The LT_{50} values for 5×10^4 and 5×10^5 PIB/g of diet were 7.36 and 6.27 days, respectively. S01-43 NPV stored for 3 years in a refrigerator (4°C) lost 79.03 percent of its LD_{50} activity, but that stored for 3 years at room temperature (approximately 22°C on the average) lost 91.21 percent of its LD_{50} activity.

TITLE: "The Geographical Distribution and Control of Millet Borer, *Chilo infuscatella* (Snellen), in Luliang Mountainous Region"

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 198-203

TEXT OF ENGLISH ABSTRACT: The altitude of the Luliang mountainous region ranges from 700 to more than 1400 m. It was found that damage done to the millet by the millet borer, *Chilo infuscatella*, changed with the altitude, being severest in the range from 1100 to 1300 m. Above 1500 m, no incidence was observed.

There was only one generation of the borer annually. Winter was passed almost exclusively in the millet stubble as mature larvae in cocoons. If June was dry, the overwintering larvae could not readily pupate and incidence was less severe. When the precipitation reached 20 mm by mid-June (which was quite unusual), the larvae could pupate promptly and injury to millet would be severe that very year.

Based on the estimated loss and economic threshold, it would not be difficult to decide if a millet field needed chemical control.

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 205-210

TEXT OF ENGLISH ABSTRACT: A survey on the susceptibility of the brown planthopper collected from different areas of Zhejiang Province to γBHC, malathion and parathion was tested by topical application in 1977. The data obtained showed that resistance of the brown planthopper to γBHC and malathion appearing in paddy rice fields between June and early July in the areas of this province was 2.4 ~ 6.8 and 3 times respectively in comparison with that of Wucun Juxian County. The autumnal generation was 4.7-fold resistant to γBHC as compared with LD_{50} of the immigrant summer generation. The resistant laboratory strain originating from the autumnal generation in Dongyang County was 11.5 times resistant to γBHC as

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 205-210]

compared with the susceptible strain from the immigrant summer generation in Wucun Juxian County. It was found that the susceptibility of the above-mentioned strain (γBHC-resistant strain) to organophosphates, such as malathion, parathion and sumithion, was the same as that of the susceptible strain.

SOURCE: Tianjin ZHIWU BAOHU XUEBAO [ACTA PHYTOPHYLACTICA SINICA] in Chinese No 3, Sep 82 pp 211-216

TEXT OF ENGLISH ABSTRACT: Based on the results of three years of laboratory and field experiments, it was found that thiocyclam hydrogen oxalate is very effective against the rice striped borer (*Chilo suppressalis*), the yellow stem borer (*Tryporyza incertulas*), the rice leaf folder (*Chaphalocrocis medinalis*) and the

[Continuation of ZHIWU BAOHU XUEBAO No 3, Sep 82 pp 211-216]

rice thrip (*Baliothrips biformis*). The characteristics, effectiveness and mode of action of thiocyclam hydrogen oxalate are discussed. Results of root-zone application showed that thiocyclam hydrogen oxalate is also a good systemic insecticide when used at a rate of 1.5 kg ai/ha. It is very effective in controlling rice borers and thrips by root-zone application.

In view of the fact that thiocyclam hydrogen oxalate belongs to a novel class of insecticides, including cartap and "diemhypo," which presumably acts by the interruption of the nerve impulse transmission at the synapses by blocking the acetylcholine receptors, it is a promising compound for the control of rice insects resistant to organochlorine, organophosphorus and caroamate insecticides.

TITLE: "The Feeding Effect of Barley Bud Meal on Pig Growth"

SOURCE: Tianjin ZHONGGUO XUMU ZAZHI [CHINESE JOURNAL OF ANIMAL SCIENCE] in Chinese No 5, 5 Oct 82 p 10

ABSTRACT: Barley of a high sprouting rate is selected for 8 hours of soaking (longer in the winter, shorter in the summer) before piling up under a layer of straw cover to allow the sprout to grow to about 1 cun in length. The barley grains that have failed to sprout are eliminated. The sprouts are dried in the sun and ground into a meal. Four experiments were carried out in 1979 to feed the sprout meal to pigs to study its effect on their growth and digestion. Results of the experiment indicate that when 3-5 percent sprout meal is added to the feed of sickly [not robust] pigs and pigs that have been weaned too early, the nutritional conversion rate is obviously improved, some feed may be saved, and the daily weight gain is higher. Adding the barley sprout meal to the feed of grown and healthy pigs, there is no effect, however. Detailed data of the experiment are reported.

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 10 Oct 82 pp 1-5

ABSTRACT: Once the goal of breeding is decided upon, the key to success or failure is the choice of parents. In order to provide the experience regarding the choice of parents, the authors proceeded to study 5 wheat breeds, which were bred out in Fujian and have been extended over large areas, in terms of their major characteristics and their pedigrees, hoping to contribute to the understanding of the evolutionary history, the blood relationship, and the genetic principle or dynamics of major economic characteristics of each of these cultivars. The wheat breeds thus analyzed include Fumai No 7, Hongmangmai, Jinmai 2148, Pumai No 1, and Longqi 35. The genealogical table of each breed is provided and the genealogical origin of each of its major merits and demerits explained.

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 10 Oct 82 pp 6-7

ABSTRACT: Fufan-16 and Fufan-17 were bred out by the Wheat Office using Jinmai-2148 and an Institute's own material B-5 (white) as parents. Offsprings of these 2 sister hybrids were cultivated, identified, and selected for 8 seasons in 5 years in Heilongjiang and several areas of Fujian and their F_6 were found to have stable characteristics and good yielding and adversity resistance in the summer of 1976. In the following winter, their F_7 were propagated in Fumei Brigade of Longhai County, Fujian for preliminary yield test and the yield was computed at above 400 jin/mu. They began to participate in joint regional cultivation experiments of Fujian and 3 South China Provinces in the winter of 1977. The morphological characteristics, yielding, suitable cultivation areas, and essential cultivation techniques are introduced. Their yield is comparable with that of Jinmai-2148 but they mature 3-8 days earlier.

TITLE: "Low Temperature Cold Damage to Wheat in the Spring and Its Protective Measures"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 10 Oct 82 pp 7-10

ABSTRACT: Majority of wheat cultivars used in the winter wheat regions of South China belong to the spring type, having relatively poor cold tolerance. These regions are frequently attacked by cold air from the north in late winter and early spring, however, and the wheat crop often suffers from various degrees of low temperature damage to become infertile. From 1980 to 1982, 126 spring type wheat cultivars (lines) of different origins were observed in each spring under natural low temperature condition at various seeding times. Major symptoms of spring low temperature damage and major factors influencing the extent of the damage thus observed are described. The paper suggests the following preventive measures: (1) Reasonable arrangement and selection of cold resistant (tolerant) breeds; (2) Reasonable adjustment of seeding time; (3) Improving fertilizer application and field management to reinforce cold resistance of the wheat; (4) If cold damage should occur, proper application of supplementary fertilizer and water may promote fast growth of undamaged tillers to salvage the crop; (5) Fumigation to protect wheat from frost.

TITLE: "Wheat High Yield Experience of Wutang of Putian"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 10 Oct 82 pp 11 13

ABSTRACT: The spring wheat harvest of Wutang Commune's 6,038 mu in 1982 averaged 397 jin/mu. Compared with the previous year, the acreage was 338 mu larger and the yield increased 21.7 percent per mu to result a total production increase of 29.0 percent. Objectively speaking, first, there was the good weather, but due to rainfall deficiency in the early period, wheat seedlings did appear to stop growing. The weather was indeed favorable in the middle and late periods. In view of technical measures, the following experience is summarized: (1) Reasonable arrangement of winter crops including such spring harvested green manure crops of 3201 mu of broad beans and rape; (2) Selecting superior breeds of wheat; (3) Early seeding at a suitable time; (4) Reasonable density; (5) Scientific application of fertilizer; (6) Intensive field management; (7) Preventing lodging, diseases, and pests and having old people and children or straw-man drive birds from wheat fields. These measures are explained in some detail.

TITLE: "Technique of Testingthe Soil, Determining the Desired Yield, for Designing a Fertilizer Application Scheme"

SOURCE: Fuzhou FUJIAN NONGYE KEJI [FUJIAN AGRICULTURAL SCIENCE AND TECHNOLOGY] in Chinese No 5, 10 Oct 82 pp 49-50

ABSTRACT: Research studies in Fujian and other provinces and experimental results in Shunchang, Pucheng, and Guangze counties of Jianyang Prefecture demonstrate that survey and chemical analysis data of soil may be used to design a fertilizer application scheme to produce a targeted yield increase. In 1981, soils were analyzed in Guangze County before a fertilizer plan was devised accordingly; compared with 1980 when the ordinary fertilizer application method was used, the yield was 81.5 jin/mu higher while the cost of fertilizer was 2.38 yuan/mu lower. A method is introduced to compute the basic fertility of soil on the basis of its chemical analysis data of alkaline decomposed nitrogen, fast acting phosphorus, and fast acting potassium. With a predetermined goal of yield of a given crop, the needs for N, P, and K are calculated and on the basis of the needs and the available supplies of the soil, a fertilizer application scheme is devised. Equations required for these mathematical calculations and the processes of computation are introduced.

I. GENERAL INFORMATION

QUESTIONS ON FORECASTING, PREVENTION OF FLOODS EXPLORED

Beijing ZHONGGUO SHUILI [WATER CONSERVANCY IN CHINA] in Chinese No 3, 1982 p 20

[Article by Hua Shiqian [5478 1102 0051] of the Nanjing Hydrological Research Institute of the Ministry of Water Conservancy and Electric Power: "Problems That Should Be Noted in Actual Forecasts for the Prevention of Floods"]

[Text] (I) The Quantitative Problem in Hydrological Science

Half a century ago, hydrology was basically a branch science that had just emerged from earth science. It mainly described hydrological phenomena. As the need for calculating flood waters in designing large water conservancy projects and for forecasting floods to prevent flooding of important rivers arose, hydrology began to develop quantitatively. Today, quantitative calculations in hydrology can preliminarily satisfy the requirements in design and in flood prevention, but its precision is not high compared to other quantitative sciences. During the latter part of the 1960's, the use of computers in the field of hydrology became widespread. Many hydrological models were developed. The efficiency of computation was improved, but the improvement in precision was still limited. This was because of the following reasons:

1. The limitations of input of information of hydrological systems

Our nation suffered mainly from floods due to rain. The amount of rainfall is the main piece of information of a hydrological system. How large an area of rain can a rain meter really represent? This question is difficult to answer. Sampling tests taken from stations of the existing network of rain measuring stations show that the gradient of rainfall in the plains is small. Within an allowable range of error, it can represent a larger area. The gradient of rainfall in the mountain regions is larger and the area it can represent is smaller. The southeast coastal region is generally a complete region of rainfall. The area represented can be larger. Rainfall in the northwest is frequently distributed in patches. The area that can be represented is very small. I have had contact in the past with the Beiyishui Chongling Runoff Experimental Station at the eastern foot of Taihangshan in Hebei Province. Taking it as an example, seven rain guages were set up within the small river basin with an area of only 50,000 square meters. The difference between the maximum and the minimum amount of rainfall, measured after one rainfall, generally reached 5 percent and the difference between individual rainfalls reached 13 percent. Of course, the strike of the mountain slopes in this small river basin had a relatively large turn, and this might have enlarged the gap of the difference. But the density of the rain measuring stations in large river valleys is much lower, and we can conclude that the error and the difference contained in the measurements of rainfall themselves are not too small. The measuring of the torrential rains in the northwest may show an even greater error and difference. Such input errors are not easily adjusted by computational methods. When reflected in the output, the improvement in precision of hydrological forecasts is limited. The precision in measuring the flow in small rivers is also limited by conditions. Because the slopes are steep and the flood waters rise and fall quickly, and if the period of measuring the flow cannot be easily shortened, then the measurement made from one bank to the opposite bank would not be the sum of the individual parts of the flow of each sectional area measured at the same time. Moreover, the error and the difference also cannot be neglected even when measurement is taking place instantaneously as the entire section of water flow occurs. The precision in measuring the flow of large rivers is generally higher, but there are exceptions, for example, in the river segments at the middle and lower reaches of the Huanghe, because certain sections are too wide, and the measuring of flow requires several hours. With the unstable silting in certain sections of the flood, the direction of the main flow frequently shifts, thereby reducing the precision of the measuring of the flow. Therefore, even if the effects of human activity are not taken into consideration, the error and the difference in the information on natural river valleys further limit the improvement in calculating precisely the hydrological quantity.

2. The limitations of the methods of hydrological calculations

Over the past 20 years and more, the theory and methods of hydrological calculations have improved. Generally speaking, the study of the laws that govern the motion of bodies of water in a river valley is a problem in hydrodynamics. Calculations of the generation of flow and confluence are all limited by the Sheng Weinan [5110 4850 0589] differential equations. In the past, the Sheng Weinan equations were very difficult to solve. Now, with the help of the computer, they can be completely solved. But the parameters in the Sheng Weinan equations and the boundary and initial conditions vary according to time and place in the river valley. In practice, frequently data of many measurements must be gathered to select the best measurements to determine the parametric values. This limits further improvement of the precisions of calculations. During the past 20 years, new models for the generation of waterflow and confluence have been proposed continuously, but the precision of calculations has not been greatly improved. This is because the structure of the models is often simplified while the actual situation is much more complex. The major factors affecting the dynamic variation of bodies of water and variations in time and space, can only be generalized using statistical methods at present. Of course the precision is limited. When limiting values beyond the range of the known data are encountered, it is more difficult to guarantee the precision of calculations. In general, the established model used for forecasting at present includes the objectively existing randomness of the elements of input and the lower cushioning surface within the space of the river valley, and there is great difficulty in further improving their precision.

3. Estimates of the effects of human activity are rough

As productivity develops, the ability of mankind to influence nature and the environment becomes greater. The effects of water conservancy and water conservation projects upon the various elements of hydrological cycles are the most visible [examples] of this. They should be given full consideration and they should be quantitatively estimated as much as possible.

The current research level indicates that qualitative judgment can be made of the changes on the surfaces of slopes in river valleys, but it is very difficult to make quantitative estimates of higher precision. For example, changes in vegetation on the surfaces of slopes will cause corresponding changes in the granular structure of the soil and this will benefit infiltration of water. The increase in coarseness of the surface of a slope will reduce the speed of flow on the surface of the slope and increase the duration of infiltration from the surface of the slope. Changing the surface of the slope into platform terrace fields and building ridges around the fields will similarly delay runoff and increase infiltration. Because the amount of construction on the surface of the slope is large, the distribution on the surface is not even, therefore, it is not practical to calculate its influence on the macrocosmic river valley precisely. Generally, we can only rely on empirical data to develop a rough estimate. Construction projects on river channels, such as reservoirs, river floodgates, flood water sluice gates or diversion sluice gates have a relatively stable relationship in hydraulics. We can use more mature hydraulic and hydrological methods in calculations and the precision is higher. But in actual forecasting, we still need to acquire all information regarding the projects on the river channels described above in time before we can carry out relatively more precise calculations. If there are many construction projects in the river channels in the river valley, and if we can only obtain information concerning a portion of the projects, then we can only make estimates.

A summary of the three points above shows that further improving precision involves the three aspects of information input (the network of stations), computational method and human activity. Therefore it is very difficult. It is very important to clearly recognize this point. On the one hand, blindly believing the forecasts and believing that every water level that has been forecast will surely be reached without even one centimeter of error and thus neglecting the problem of precision in quantitative calculations, a problem that commonly exists in earth sciences can be avoided. On the other hand, complete distrust of hydrological forecasting and regarding it as a theoretical science and disregarding it completely can also be avoided. Only by correctly understanding the precision of quantitative hydrological forecasts can we correctly use the forecasts and avoid causing unnecessary loss.

(II) Becoming Familiar With the Weather, Flooding and Natural Geographic Characteristics of the River Valley Can Prevent Serious Mistakes in Actual Forecasts

The forecasting plan is the most important tool in forecasting. This view is generally accepted. But, can we acquire the initiative in preventing floods and guarantee that our forecasts will not be seriously wrong by relying only on the forecasting plan? The answer is not affirmative. In special situations, simply relying on the forecasting plan will not completely avoid serious mistakes. Also, if we disregard the problems that might exist when drawing up a forecasting plan, at least in the many forecasting plans that have already been established, we cannot completely reflect the effects of weather, flooding and natural geographic characteristics of the river valley. Therefore, if the forecaster does not possess a profound knowledge of the above characteristics of the river valley, and if he relies only on the forecasting plan to make his forecasts, it is very possible that he will not avoid making forecasting errors while seizing the initiative in his work and while encountering special conditions that have occurred. The following examples will explain this.

1. Understand the characteristics of torrential rains in the river valley and seize the initiative in flood prevention

First we must understand the seasons in which torrential rains occur in the river valley. For example, torrential rains generally occur between the beginning of July and the middle 10 days of August in ordinary years in the Huaihe river valley. But the earliest occurrence of floods due to torrential rain is at the beginning of June. At this time, wheat planted on the river beaches has not been harvested yet, and when torrential rain falls, a labor force must be organized before the flood water floods the beaches to harvest wheat in time. This creates a tense situation. Therefore, starting from the beginning of June, flood prevention forecasters must watch the movement and development of rainy regions south of the Changjiang closely to seize the initiative in flood prevention. Also, for example, after the middle 10 days of August, the possibility of occurrence of large floods in the entire river valley is very remote but the threat of typhoons to Shandong and the northern coast of Jiangsu still exists. Especially in Yishu River, only several hours after a torrential rain, flood peaks will occur in Linyi and Danguanzhuang. When the floodwater surpasses the safe amount of downstread discharge, the sluice gate at Jiangfenkou must be used, the waterflow of the Yi River must be diverted into the Shu River, and the sluice gate on the Xinshu River must be used. To seize the initiative in flood prevention, the movements of a typhoon over the Pacific, the possible landing routes and the possibility that the typhoon will change to a tropical low pressure system and move into the Yi-Shu river valley must be closely monitored during this period to strengthen flood forecasts and preparatory forecasts. This way we will avoid being caught unprepared when torrential rains fall because we have let down our guard during the latter period of flooding.

2. Understanding the characteristics of flooding in river valleys is useful in revising forecasts and improving accuracy

By analyzing the water of large and small floods pouring into a river valley, we can understand the characteristics of the fullness or leanness of the peaks, variations in the time of propagation of the floodwaters, regulation and interference of floodwater in the main streams and tributaries, the characteristics of deformation, the rise and fall of water roping during the course of downstream discharge of floodwaters in river channels, the regulatory and storage functions of natural lakes and lowlands, and the characteristics of the tidal effects at river mouths. They all have a great reference value for revising actual forecasts, and sometimes may play a key role. Take the southern Canal before 1963 as an example. The safe discharge of the river channel from Chenggouwan to Dezhou dropped from 1,100 cubic meters per second to 400 cubic meters per second. The capability of the river segment for passage of floodwater becomes smaller downstread, creating blockage. This is more pronounced when floodwater continues to flow. The relationship between the water level and the volume of flow at each of the corresponding stations along the river has been shown to be opposite the looping effect in ordinary river channels, and looping of follow-up floodwaters is even greater. The relationship between trough storage and the volume of flow also shows corresponding looping changes, but forecasting plans consider only changes in the rise and fall of water to derive the parameters of the floodwater. This is the average value of the slope of the looping floodwater over the years. The precision is not high.

But how can we estimate looping changes for the next flood? That depends on a profound understanding of the characteristics of the flood water in the river segment and the experience acquired in past forecasts to correctly estimate looping changes. The precision of forecasting can visibly improve. It can be seen that a profound understanding of the characteristics of floodwater in the river segment or the river valley is a precious treasure of a mature forecaster. It is also a necessary preparation to avoid major forecasting mistakes.

3. Understanding the natural geographic characteristics of the river valley is also an important apsect of a successful forecaster

The elements taken into consideration by a forecasting plan are mostly elements that are directly related to the movement of the bodies of water. The plan only describes in general the natural geographic characteristics of the river valley, such as vegetation, soil, the shape of the river valley and the fall of the slope, the density of the river network, the section of the river channel and the specific fall, the lakes and beaches of river troughs, ground surface erosion (including slipping slopes during the rainy season). Generally they are not the major parameters used in quantitative calculations in the plan.

Under ordinary conditions, the effects of natural geographic factors are relatively stable in the river valley, but under special conditions, the effect of a certain factor may be very large. At this time, simply relying on the forecasting plan may cause mistakes in forecasting. For example, there is a relatively wide natural flood detention basin at the mouth of the Zhanghe where it emerges from the mountain. Each year after the flooding period begins, water of the first big flood pours into the flood detention basin, and nearly 10 million cubic meters of water are lost. If this situation is not understood and if it is not handled in a special way, the forecast of the first floodwaters may very possibly be over estimated and cause a scare. Also, for example, if several rains had already fallen during the early period of the year in the loess plateau region at the middle reaches of the Huanghe and if such rains were followed not long afterwards by torrential rains, then large slides might easily occur. This would greatly increase the sand content of the flood waters. The peak of such mud flows is a combination of the peak of clear flood waters and the peak of mud flow. If the forecasting plan is drawn up from the data of flood waters having a low sand content, generally speaking, the forecast value will be smaller. The above shows that in actual forecasting, it is necessary to be familiar with the natural geographic characteristics in the river valley.

A summary of the three above points shows that to guarantee the precision of actual forecasting for flood prevention, besides drawing up a good forecasting plan, we still need to be familiar with the weather, flooding and natural geographic characteristics of the river valley before we can seize the initiative and prevent mistakes.

(III) The Effects of Water Conservancy and Water Conservation Projects Upon the Flood Water in the River Valley Must Be Fully Understood

1. In forecasting for river segments, we must first understand the ability of the embankments of each river segment to discharge the flood water and the dangers of unsafe sections of embankments at different water levels. The amount of flow over the flat beaches must be understood. To guard against large flood waters, we must understand the amount of flow over level embankments, and we must understand the situation of water blocked by bridges where there are bridges. In river segments where sectional scouring and silting changes are larger, we must understand the situation of sectional scouring and silting, the shift of the main flow, the horizontal specific fall, the intersections of the main flow and structures in the water such as bridges at a high water level. The flood discharge ability of the embankments can be determined by analyzing the water surface lines of past floods and the curve of the relationship between the water level and the amount of flow at each station within the river segment. The lowest and the average water levels causing danger in the river segment can be derived by studying dangerous situations of the embankment which occurred at different water levels of past floods. Knowledge about the amount of flow over flat beaches is mainly used for seizing the time to harvest crops planted on the beaches. The knowledge about the amount of flow over level embankments is used generally to calculate the maximum downstream discharge the enbankment may possibly bear after elevating the secondary low banks between fields. Water blocked by bridges may dam up the upstream water level. We can use hydraulic or hydrological methods to calculate the difference between the upstream and downstream water levels. In river segments with dynamic river beds where the sections change drastically,

the direction of flow of the trunk water flow and the bridge do not intersect at right angles and thus the amount of downstream discharge is reduced. The amount of downward discharge at the time the direction of flow changes and the water surface line of the upstream backwater section can be calculated by hydraulic or hydrological methods.

2. The effect of medium and small (I) reservoirs on the tributaries upon the regulation, storage and discharge of flood waters. Generally, we can understand the situation of the flood waters entering the reservoir, the water level in the reservoir and the discharge from flood forecasting radio stations or telephone reports, and thus understand their clipping function in the course of the flood. Because of improper use, some reservoirs have to increase the amount of downstream discharge of continuous floods to guarantee the safety of the large dam. We must also consider this unfavorable effect. For medium reservoirs with a reservoir capacity over 10 million cubic meters, we must first calculate the amount of overflow of water over the dam at various high water levels. For earth dams, we should generally estimate its gradual downward shearing and enlargement of the sluicing mouth to derive the amount of flow of the peak of the flood that will cause the dam to collapse. For concrete dams, we should generally consider the use of the formula for calculating the instantaneous collapse of the dam. After calculating the flow line of the amount of flow that will cause the dam to collapse at the dam site, we then derive the amount of flow at the peak of the flood water and the flow line of the water reaching a certain town in the hydrological section. In this way, when a certain reservoir shows signs of danger and may possibly burst, we can find the amount of flow of the peak of the flood at the town downstream when the dam collapses by how fast the water level of the reservoir rises and this information can be used by flood prevention departments.

3. We must understand at all times the amount of water diverted along the river and the situation of diverting water from other river valleys to revise the forecasts.

During the 32 years since the founding of the nation, many diversion projects have been built on rivers. Some rivers have both diversion projects on the rivers themselves and diversion projects that span several river valleys and divert water from other river valleys. General diversion projects all have manually controlled floodgates or natural diversion weirs at the diversion point. The amount of diverted water of the single tunnel (or single width) and its relationship with the water level can both be derived using hydraulic formulas and their coefficients can mostly be determined by experiment using models. If hydrological stations have been set up downstream from the sluice gate weir and if there are hydrological testing data, then the coefficients can be approximately determined, and their precision can be more reliable. The flood prevention and forecasting departments must grasp these data and draw the relationship between it and the water level of nearby hydrological stations for future use. When water is diverted from other river basins, the predetermined diversion points that span river basins should be made in the flood reports. The mouth of the diversion conduit should be made the outflow and the opening of the other river basin should be made the inflow, and the forecast should be revised whenever possible according to the data provided by the flood reports. For example, the Tuhe and Maxiahe river valleys inside Shandong Province frequently diverted water from the Huanghe for irrigation. When torrential rains occur as the water of the Huanghe is being diverted to the river basin, although the gates are immediately shut down, the amount of water that had already been diverted into the river troughs of the river valley, the variation of the water content in the soil within a fixed area of both sides of the diverted river channel and the rise of the underground water level caused by the diverted water should still be calculated. These effects must be considered in time before we can correctly forecast flood waters from the torrential rain in the valley basin.

4. The characteristics of the flood-diversion area must be grasped.

The flood-diversion area that has been determined in the flood prevention plan and that has intake and outflow control floodgates, such as Changjiang's Jinjiang flood-diversion area, mostly has complete information such as the water level both upstream and downstream from the intake floodgate, the curve of the relationship between the height of the opening of the floodgate and the amount of the incoming flood water flow, the curve of the relationship between the water level and the volume of the flood-diversion area and the water level both upstream and downstream from the discharge floodgate, the curve of the relationship between the height of the opening of the floodgate and the amount of the discharged flood water flow. They can basically satisfy computational needs. But, when we encounter especially large flood waters and have to temporarily open up a flood-diversion area, such as the People's Embankment in the Jinjiang section where there are no controlling floodgates and where temporary embankments have to be set up to divert the flood water, the embankments downstream frequently have to be removed to allow the flood water to discharge into the main trunk [sic] river again and to temporarily become a flood water lake during the latter part of diverting the flood waters. When such a temporary flood-diversion area diverts the flood water, the flow of the diverted flood water must be calculated by the flood prevention department. By so doing, the department must understand the conditions under which the water passes through the floodgate such as the width and the average depth of water at the gate, the water level behind the embankment. Then the specific fall of the downstream water surface at the mouth of the trunk flow is used to calculate the amount of water flow of the downstream discharge. By comparing this with incoming water upstread we can check the amount of flow of the diverted waters at the gate. The coefficient of the corrected formula for the flow over the weir can be used to calculate the amount of flow of the diverted waters at the funnel mouth of other embankments in the river segment. The corresponding interior water level in the area of water accumulation inside this temporary flood-diversion area can be found on the map. This is the initially derived water level inside the flood-diversion area. Then we can calculate the interior water level at the end of each period, determine the exact moment when the normal free flow changes to flood, and plot the course of the flow and volume of the incoming flood waters that are gradually diminishing at the time of diversion. We can then determine when is the appropriate time to discharge the water downstream in the flood-diversion area.

5. Outlet control gates and their impact in river channels

The outlet control gates in river channels regulate the release of water to prevent flooding and to store water for drought resistence. At present, gates have been built in many river streams. Because most efforts before the arrival of big torrential rains are to resist drought, therefore, the use of controlling gates in river channels is a factor that cannot be neglected. Let us set aside temporarily the issues of anti-flood management and organization. The forecasters involved in the work of flood prevention, should familiarize themselves and grasp the designs and data materials of these in order to cooperate and utilize these gates correctly. For example, the conditions are laid out in the design on the amount of flood discharge, the corresponding water level and the fall upstream and downstream of the operating gates, the maximum operating head of the gates and the surplus flow exceeding the level of discharge when the water floods over the gates, determination of the downstream flooding area when the embankments on both sides burst, and the relationship between the water level upstream of the operating gate when the gate closes, and the amount of water stored in the river channel. These data not only are needed in revising flood forecasts, they are also necessary in further modifying the forecast. When making actual forecasts, we must especially pay attention to the inspection and the testing of the discharge coefficient of the operating gates when the water level is high (ordinary floodgates lack the capability to determine the discharge rate for high water portions). Only after grasping these key data, can we gradually make more reliable forecasts of river segments that have floodgates.

6. The effects of large key water conservancy projects

The data on large key water conservancy projects on river channels are relatively complete and there is a network of flood reporting stations especially set up for them. For example, Sanmenxia on the Huanghe, Dahuofang on the Hunhe, Guangting Reservoir on the Yongdinghe generally do not have many problems with gathering information and forecasting. The key is to control the flood waters that have discharged into the downstream areas and to handle any possible continuous flood water that may occur upstread. The plans for discharging the flow is calculated from the forecasts of incoming water into the upstream and downstream areas. The safety of the large dam must be guaranteed and the downstream discharge must be controlled to prevent any damage to the downstream area by discharging flood waters. Even when damage is unavoidable, we must still propose the most rational discharge plan to lessen the damage by flood waters as much as possible. According to the discharging plan, we can synchronize the information on flood in all areas to forecast the course of flood waters at all of the downstream places.

7. The effects of small surface water conservancy and water conservation projects

Generally, surface projects do not have a source of information during the flooding stage, therefore, there can only be rough estimates. The effect of surface projects on slopes can only be estimated by analyzing the hydrological data of a year ago or several years ago, and the information is used to revise the forecasting plan. The amount of water at the bottom of small (II) reservoirs or large ponds or dams that are widely distributed is different before the occurrence of each flood from torrential rain, and the situation of every small (II) reservoir is also very different, therefore it is very difficult to estimate. When there are many small (II) reservoirs in a river basin that is seriously damaged by flood, only a portion of these small reservoirs has flood reporting conditions. In this situation, it is necessary and also possible to estimate the effect. There are many methods of estimation. This writer had mentioned one method in an article published in the SHUILI XUEBAO [WATER CONSERVANCY JOURNAL] of October, 1959. We should clearly survey all of the small surface stations in the river basin and their controlled water level during the flooding period and the reservoir capacity to prevent flooding, and the relationship between the height of the dam and depth of the water in the reservoirs and the amount of discharge. Then we should generalize them as one reservoir and derive the relationship between the average depth of water and the total reservoir capacity for flood prevention, and the relationship between the average depth of water and the total amount of discharge. With these relationships, we can develop computations for the reservoir by combining these relationships with the relationship between rainfall and runoff. But when rainfall is heavy, we should also compare the amount of torrential rainfall and the capacity of the reservoir in order to take measure against floods and estimate the amount of flow from small (II) reservoirs that might burst and from dams that might collapse.

Water conservancy projects do affect floods to varying degrees in rivers in the eastern half of our nation. It is not wise to completely neglect these factors. Under present conditions, an overall understanding of the projects within the river valley, making necessary estimates according to hydraulic and hydrological data gathered and according to a portion of the real-time information to revise forecasts will help us avoid making major errors in forecasting.

(IV) Flood Forecasting Must Be Combined With Flood Dispatching In Order to Better Perform the Task of Flood Prevention.

Simply forecasting floods does not serve a great function when especially large floods are encountered. This is because when such situations occur, frequently, the ability of the existing embankments to discharge floods has already been surpassed, and we must take the initiative to separately discharge a part of the flood water and sacrifice a smaller flooded area in exchange for victory in overall flood prevention. We must combine forecasting with the dispatching of floods before we can realize greater results. To facilitate understanding, we will take the actual case of preventing the big flood of the Changjiang and Huaihe in 1954 as an explanation.

1. Changjiang: During the last 10 days of July, 1954, diversion had already taken place in the Jinjiang flood-diversion area. At the time, the peak flood had already passed. The north floodgate at Taipingkou (intake floodgate) was still open to continue to take in flood waters. The reason that we did not dare to close the floodgate was that the downstream water level at Jianli

was level with the top of the embankment and we were building a secondary low bank between fields for fear that after the floodgate closed, the water level would rise. But, August and September are the time when the Chuanjiang brings water, and the chance of the greatest flood of the year occurring in August is the highest in the Chuanjiang. At this time, the remaining capacity in the Jinjiang flood-diversion area was already very small, and we had to close the intake floodgate and use the south floodgate (the discharge floodgate) to drain the water from the Huduhe into Dongting Lake, so that the empty part of the reservoir would have room to receive the Chuanjiang flood waters in August. But, would the Jianli water level rise after closing the north floodgate? We conscientiously analyzed and studied and discovered that the water level at Jianli was higher than the corresponding water levels at Shashi and Jianli by several meters under ordinary conditions. The water level was mainly controlled by the water level at Lingji, the town at the eastern mouth of Dongting Lake (representing the water level of the large body of water), while the water in the four rivers leading into Dongting Lake was receding. The incoming water from the four river mouths had already stabilized. The amount of stored water in the entire Dongting Lake and the eastern Dongting Lake area had reached the maximum value (about 34 billion cubic meters and 16.8 cubic meters). Therefore, closing the north floodgate to divert the flood waters at Jinjiang would not cause the water level at Jianli to rise. A decision was made at a departmental meeting to notify us to immediately close the north floodgate and open the south floodgate completely to make as much as we can of the reservoir capacity. The north floodgate was thus closed on July 27. As expected, during the first 10 days of August, torrential rain fell over Jialingjiang. At the time, there were only a few rain guaging stations and there were only a few years of data. We used only the information of eight floods, five floods between June and September, 1952 and three floods in July, 1954, to analyze the relationship between the average amount and the net amount of rainfall in the flow producing area. This relationship was very good. Also, because the area of the river basis was too large (about 160,000 square kilometers), we could not use unit lines so we changed to using standard runoff distribution curves. Using these two tools, we forecast the course of flow at Dongjintuo, the outlet spillway of the Jialingjiang. Then we used the combined flow to forecast the course of flow at Cuntan Station in Chongqing on the main stream of the Changjiang. We then derived the amount of downstream flood water and calculated that the highest water level in shashi would reach 45.63 meters if the flood waters were not diverted. To keep the water level at Shashi at or below 44.49 meters as much as possible, we still needed to separately store 2.5 billion cubic meters of flood water. At the time, the flood-diversion area had already stored 4.8 billion cubic meters, and it could not take in any more. Therefore, we proposed a plan to break open the eastern embankment of Huduhe to separately store the flood waters and thus the highest actual water level in Shashi was controlled at 44.67 meters (0.18 meters higher than the guaranteed water level). We preserved the large embankment of Jinjiang and the production of the several million mu of farmland on the northern bank, the lives and the safety of the people. After making a flood forecast, we continued as a matter of course to modify and readjust in diverting flood waters. The latter is the true goal in flood prevention, and when combined with previous efforts, we will be able to develop a greater "advisory" function.

2. Huaihe: During the middle 10 days of July in 1954, all of the flood water storing area beyond Zhengyangguan on the Huaihe had already been filled. After 15 July, a third torrential rain occurred over the Huaihe. The center of the rainstorm was over the middle and lower reaches of the Shayinhe, over the Huaihe's tributary, the Shihe and over the Weihe river basin. At the time, the flood waters at the upper reaches of the main stream of the Huaihe had not receded. With the water coming from the Jinhe, the Shihe and the Weihe, the large Huaibei embankment below Zhengyangguan was threatened. According to calculations of the flood waters, the forecast flow of the flood peak at the Zhengyangguan was 9,780 cubic meters per second, surpassing the high water level of 9,000 cubic meters per second and this would last for 4 days. If we used Wabuhu and Shouxihu to store the flood water, the amount of flow at the flood peak could be reduced to 7,680 cubic meters per second. Therefore, at 0030 hours on July 20, the most serious threat to the large Huaibei embankment was removed (the large Huaibei embankment protected the safety of nearly 10 million mu of farmland in the Xuaibei plain and the medium and small towns in the two prefectures of Fuyang and Shuxian). But the serious threat was still to come. If the large embankment of Hongzehu or the large embankments of Gaoyouhu and Liyunhe burst, 10 million mu of farmland in norther Jiangsu and a large number of towns would be flooded. All of the flood waters of the Huaihe would have to pass through Hongzehu for downstream discharge. Besides the main irrigation canal which diverted and discharged 800 cubic meters per second of flood water, the rest must all pass through the Sanhe floodgate (with a designed flood discharge of 8,000 cubic meters per second) and discharge into Gaoyou and Baoying Lakes (abbreviated Gaobaohu), and then discharge via spillways into Changjiang. To guarantee the safety of the large embankment of the Hongzehu, the highest water level at Jiangba should not surpass 15.2 meters. To prevent the embankments of Gaoyouhu and Liyunhe from bursting, the highest water level in Gaoyouhe should not surpass 9.5 meters. Therefore, after forecasting the course of the amount of waterflow entering Hongzehu, there were still two problems that had to be solved: the amount of rainfall over the area surrounding Hongzehu and on the surface of the lake during the forecast period and a plan to utilize the Sanhe floodgate. Concerning the first problem, we referred to rainfall data over the lake area during the same periods in the past, especially analyzed and studied the amount of rainfall during the latter period of the big 1931 flood. Because the amount of rainfall was not large, we made a slightly safer estimate and the effects were very small. Therefore, the key of the question was the plan to utilize the Sanhe floodgate. If we increased the amount of flow at the beginning, the water level in Hongzehu would quickly drop, and the outflow from the Sanhe floodgate would be small, but the water level in Gaobaohu would rise quickly. The amount of discharge into the spillways in the Changjiang could be increased. If the Sanhe floodgate could not control the downstream discharge in time, it was very possible that the water level in Hongzehu would be lower than 15.0 meters while the water level in Gaobaohu would surpass 9.5 meters. Conversely, when the Sanhe floodgate reduced the amount of flow to force the water level in Hongzehu to rise, then because the water level in Gaobaohu was lower and the amount of water flowing into the Changjiang via spillways was small, there was the possibility that the water level of Hongzehu would surpass 15.2 meters. The best plan was to keep the water levels in Hongzehu

and Gaobaohu both below 15.2 meters and 9.5 meters respectively, and to maximize the flood prevention capacity each lake shared. At the time, to guarantee the safety of the Lixiahe area in northern Jiangsu Province, somebody proposed to build a temporary flood-diversion embankment employing 300,000 workers, diverting the flood waters north of the main irrigation canal in northern Jiangsu and south of the temporary flood-diversion embankment and let the flood water flow into the sea. This plan involved mobilizing a massive labor force, spending large funds, and flooding some of the land, but yet it could not ensure that the new embankment would allow water to pass. Therefore, we calculated the various plans of utilizing the Sanhe floodgate in order to rationally utilize the reservoir capacities of Hongzehu and Gaobaohu and the capability of the spillways leading into the Changjiang to discharge the flood. At the time, there were no computers. Everything had to be calculated by conventional methods. Finally, the best plan was found. The Sanhe floodgate was opened to discharge the flood waters until the water level in Gaoyouhu reached 9.2 meters. The Sanhe floodgate controlled the downstream discharge at 9,000 cubic meters per second. When the water level in Gaoyouhe rose to 9.4 meters, Sanhe floodgate controlled the downstream discharge at 8,500 cubic meters per second. Using this control method, we forecast that the highest water level at Jiangba in Hongzehu would be 15.20 meters, the highest water level of Gaoyouhu would be 9.40 meters, and this was a more ideal operating method. After operating the Sanhe floodgate according to this plan, we avoided building a new embankment to divert the flood water and to guide the water into the sea. By so doing, we could still guarantee the safety of the Lixiahe area in norther Jiangsu Province. The highest water level actually measured at Jiangba in Hongzehu during the operation coincided with the forecasts. The highest water level in Gaoyouhu was 9.32 meters, a difference of 8 centimeters.

The above example further shows the significance of combining forecasting methods with flood prevention and control methods.

Conclusion: The problems that we may encounter in actual forecasting in the effort to fight floods will be very complicated. This article has only briefly introduced several problems that should be noted. Of course, not everything is included. But, in view of the above description, we can already demonstrate that simply relying on the forecasting plan is insufficient. To be a good forecaster, familiarity with the hydrological and meteorological characteristics of the specific river basin and human activity and especially the situation of water conservancy and its protection projects is very important. In addition, flood forecasts can function as the "ears and eyes" of flood prevention work, and by combining forecasting efforts with flood water control we can give full play to this "aid" function. This function is very obvious in actual flood prevention.

'GUANGMING RIBAO' ON PRC AGRICULTURAL STRATEGY

HK161210 Beijing GUANGMING RIBAO in Chinese 7 Nov 82 p 4

["Economics Trend" column: "Summary of Views Put Forward at the Symposium Held by the Chinese Agricultural Economics Society"]

[Text] The Chinese Agricultural Economics Society held its 1982 symposium in Hefei during the last 10 days of October. The meeting discussed China's strategy for agricultural development and the agricultural responsibility system. We now summarize the main views put forward at the symposium as follows:

China's Strategy for Agricultural Development and Ways to Achieve It

With respect to China's strategic objective of agricultural development, different views were put forward at the meeting. There was a view which held that, fundamentally speaking, China's strategic objective of agricultural development is to achieve modernization of China's agriculture, that is, to have a developed agriculture, prosperous rural areas and a good environment. Another view held that China's future agricultural development should be centered on developing commodity agriculture, ecological agriculture and scientific and technological agriculture and changing the self-sufficiency, disproportion and the present state based on traditional experience.

With respect to the ways of achieving China's strategy for agricultural development, some comrades aired their views as follows: the fundamental way to develop China's agricultural production is, on the basis of improving land productivity, improve agricultural labor productivity. At the same time, with regard to the content of production, it is necessary to reform the agricultural production and rural industrial structure. Reforms in agricultural production refer to a shift from paying exclusive attention to grain and viewing things from the angle of 1.5 billion mu of cultivated land to paying simultaneous and vigorous attention to diversified undertakings and viewing things from the angle of 9.6 million square kilometers of our territory and taking the road of all-round development of agriculture, forestry, animal husbandry, sideline occupation and fishery. Reforms in the rural industrial structure refer to the gradual development of comprehensive operation by agriculture, industry and commerce. Some comrades emphatically pointed out that it is necessary to pay attention to the "rate of formation." In organizing production, it is necessary to reform the structure of agricultural production areas and the administrative structure of enterprises. That is to say, it is necessary to shift from the structure of "small but complete" areas and enterprises to specialized production in order to constantly improve the standard of mass agricultural production. With respect to the key element of productive forces, it is necessary to readjust and reform the structure of rural labor force technology and energy resources: We should absorb, by means of developing the range and quality of production, the surplus labor force in the rural areas and gradually transform them on the spot into nonagricultural population; we should reform the structure of agricultural technology by taking the road of integrating organic agriculture with inorganic agriculture; in reforming energy resources in the rural areas, great attention should be paid to the utilization of biological energy but it is also necessary to increase the supply of industrial energy such as petroleum, coal and electricity. With respect to the utilization of soil, we should take the road of intensive farming and pay attention to the expansion and protection of agricultural land. The core of agricultural development strategy is to improve economic results. We should base ourselves on this when determining and testing the ways and measures for achieving agricultural development strategy.

Grain strategy is a basic strategy of our agriculture. We should apply the strategic thinking of integrating long-term with short-term planning to guide and solve China's grain problem. Reliance on the existing cultivated land can only slightly ameliorate China's grain shortage. In order to fundamentally solve the grain problem, we should rely on 14.4 billion mu of our territory. We should base ourselves on the existing land for growing grain and have the whole territory in mind. At present, we should stabilize the acreage of commodity grain-growing areas. Resolute steps should be taken to readjust the high-yield cultivated land suitable for growing grain which has been planted with low-yield industrial crops.

The Contract System Based on Output with Household as Production Unit Will Exist for a Long Time to Come

The comrades who spoke at the meeting hold that the contract system based on output with a peasant household as the unit is a form of socialist cooperative economy. Some comrades expounded this point from the following three aspects: 1) It is an economic structure integrating a unified administration with a decentralized one, with the one being interdependent on the other. 2) It is a form of contract and distribution in a production team based on unified accounting. 3) The households signing contracts based on output will develop in the direction of a union based on specialization.

Quite a few comrades held that the contract system based on output with the peasant household as a production unit conforms to China's characteristics. It has been chosen by the peasant masses after many years of practice and it will exist for a long time to come. The essential basis they provided are as follows:

1. The relative stability of blood relationship in the household of Chinese society. In China, the organizational form of taking a household as the production unit goes back to ancient times. At present, China's agricultural production is still conducted in a decentralized manner and is primarily done by hand. Under these circumstances, this form, which is readily acceptable to the peasant masses, has a relatively stronger force of inner attraction.

2. The requirement of the feature of agricultural production. Some comrades held that the technological level of our agriculture was low. The previous method of great concentration (concentration of property, management, distribution and labor) was practically a method of running agriculture with the method of running industry. The organic structure of capital in modern industry is very high, its division of labor is well-organized and each producer only undertakes work for a certain link. It has both fixed quantitative and qualitative requirements and scientific means of inspection. Therefore, we must and are able to conduct concentrated management in industry. However, this method cannot be applied in the present agriculture which has a very low level. Agriculture is the production of living materials. The conditions to which it is related are more complicated than those of industry and various factors such as weather, soil and the contents of fertilizers and water constantly change. Unless future agriculture can be turned into factory production, it will be necessary for laborers to make frequent responses and policy decisions according to circumstances. This makes it necessary for the agricultural administrators and producers to be in unity as much as possible. Therefore, it is relatively appropriate to have a household as the production unit. Some comrades also raised a question from another angle. In agricultural production, due to the considerable influence of natural force, the circulating labor thrown into production is frequently out of proportion to the final yield of labor. The unified calculation of workpoints on the basis of work done has brought about a lot of problems. The adoption of the contract system can prevent contradictions because it places the final responsibility for production on the households. At the same time, agriculture also has a feature characterized by the intermittence of labor. By adopting a household as the production unit, the peasant households can make full use of the intermittent time to engage in diversified undertakings and make a comprehensive utilization of various agricultural and sideline products in a more effective way.

The comrades who spoke at the meeting said that the current contract system based on output with a household as the production unit is a very "flexible" organizational form. Viewed from the practical experiences at home and abroad, it not only suits the present needs but also the future needs for achieving agricultural modernization. Therefore, this organizational form will exist in China for a long time to come. Some people, basing themselves on their previous long and habitual understanding, regard the contract system based on output with a household as the production unit as a retreat, a provisional measure or an expediency. The peasants do not feel at ease with this either. A clear definition of the protracted nature of this organizational form will help to ease their minds.

PRC PEASANTS' PURCHASING POWER INCREASES

OW151421 Beijing XINHUA Domestic Service in Chinese 0047 GMT 15 Nov 82

[Excerpts] Beijing, 15 Nov (XINHUA)--What will be the trends in the brisk rural market after the autumn harvest this year? The recent surveys of supply and marketing cooperatives in some provinces and municipalities show: The peasants' purchasing power after the autumn harvest this year will continue to increase by a big margin, the brisk market will come earlier and persist longer in the countryside this year and there will be some changes in the direction in which peasants will use their purchasing power.

Rural market surveys have been conducted by supply and marketing cooperatives in Zhejiang, Jiangsu, Hunan, Hubei, Shandong, Henan, Heilongjiang, Jilin, Liaoning, Gansu, Guizhou, Sichuan, Guangdong, Anhui, Shanghai and Shanxi.

The Hubei provincial supply and marketing cooperative has conducted a sampling survey of 214 peasant households scattered throughout the province, which shows that each household's income from agricultural and sideline production this year will increase 33.5 percent over last year and that each household's average income will be 1,178 yuan. A survey of 310 peasant households shows that each of the households will spend more than 700 yuan in the market, a 33 percent increase over last year.

The surveys of some rural areas show that since large numbers of commune members are anxious to increase production after the institution of the production responsibility system, they now give first priority to buying means of agricultural production. The amount of money 139 peasant households in Jiangsu have used to buy means of agricultural production after this year's autumn harvest has increased 47.8 percent over last year.

The surveys conducted in various areas show that after buying means of production and building houses, many peasants will spend their money mainly on consumption articles. Famous-brand bicycles, sewing machines and desk clocks are still very much welcomed by people in the countryside.

METHODS OF SOWING WHEAT IN FURROWS EXPLAINED

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 9, 20 Sep 82 p 11

[Article by Li Jiwu [2621 4949 2976], Crop Institute, Chinese Academy of Agricultural Sciences: "Markedly Increased Yields From Furrow Sowing of Wheat and Concentrated Fertilization"]

[Text] A combination of sowing wheat in furrows, concentrated fertilization, and compacting of the soil links traditional experience to modern scientific techniques for all-around measures in crop resistance, consistent yields, and increased yeidls. This results in pronounced consistently increased yields particularly in arid, infertile, aline-alkaline land, and in the far-flung moderate and low yield of the arid northwest.

Advantages

(1) Sowing of seeds in deep furrows covered with a shallow layer of soil is a way to get enough soil moisture in arid places to be able to sow wheat, and to sow more wheat on time. Since soil moisture conditions in the bottoms of furrows are better relative to the soil surface, seedlings grow evenly, completely, and quickly, and their root systems develop. They are able to absorb a great deal and plants are sturdy, with the result that the wheat's drought resistance is increased.

(2) In places where wheat is prone to freeze damage, use of the deep furrow, light cover method of sowing makes the plants grow sturdy, and it can lower the position in the ground of tillering nodes. When tillering nodes are relatively deep in the soil where soil moisture conditions are better and there is less variation in temperatures, soil temperatures are evened out, and the number of dead seedlings resulting from freeze damage to tillering nodes is reduced. Furrow sowing also helps accumulate snow to withstand cold. This both saves work and trouble as compared with covering the wheat with sand or pulverized soil.

(3) Inasmuch as soil alkalinity and salinity is distributed in a "T" shape, by forrow sowing wheat in saline-alkaline areas opening of the furrows pushes the salt toward the ridge along the top of the furrow where it tends to concentrate serving to protect the seedling from coming in contact with it down in the furrow. Seedling roots and tillers develop commensurately enabling the plants themselves to increase their ability to withstand salinity and alkalinity.

(4) Watering fills the seeding furrows with soil, which checks the growth of small tillers and promotes growth of large tillers. In addition, the base nodes of wheat stalks are buried in the soil and are able to grow node roots, thereby greatly increasing the wheat's capacity to absorb nutrients and resist lodging. This is a good way in which to yet high yields without lodging.

(5) When sowing in furrows is combined with hilling, the back of the furrow becomes a trough, and because of the deepening of the location of the rhizosphere, the temperature of the rhizosphere is relatively low and constant. This can strengthen the root system's vitality and prevent premature degeneration of the root system for relatively good results in increasing plant ability to withstand hot dry winds during its later stages of growth.

(6) Furrow sowing in combination with concentrated fertilization entails placing the fertilizer beside the seeds, the fertilizer and the seeds being separated from each other. Nutrients are concentrated and the fertilizer utilization rate is high.

(7) Furrow sowing in hilly areas can reduce ground runoff and prevent soil erosion. In irrigated areas, when used in combination with furrow irrigation, a saving in water can be effected.

(8) Compacting the soil plays an important role in arid areas in increasing soil and conserving soil moisture.

Results of experiments everywher show that furrowsowing has brought varying degrees of inrease in yields. Take Beijing Municipality as an example. Comparison of figures for furrow sowing and flat sowing in 15 cases showed yield increases of less than 10 percent in 40 percent of the cases. Yield increases of from 10 to 20 percent occured in 33 percent of the cases. In 27 percent of the cases, yield increases were above 20 percent. Another example was Hengshui Prefecture in Hebei Province where statistics from seven places showed average yields of 469.7 jin per mu from furrowsowing versus yields of 417.8 jin per mu from flat sowing, 51.9 jin per mu more from furrow sowing for a 12.4 percent increase. Four places were in low yield areas where the average yield from furrow sowing was 208.3 jin per mu and 169.9 jin per mu for flat sowing, which was 39.4 jin per mu, or 22.6 percent, more from furrow sowing. When furrow sowing was used in arid and alkaline medium or low yield level field plots, the extent of increase in yields was greater.

Method

The specific method used in furrow sowing of wheat may be roughly divided into the following steps:

The first is use of the interchangeable machine chassis used by the Crop Institute of the Chinese Academy of Agricultural Sciences for furrowing, concentrated fertilizing (60 jin per mu of ammonium bicarbonate and 100 jin of calcium superphosphate), and soil compacting, which are completed in a single combined operation. The furrow sowing machine uses a hoe-shaped furrowing device to make furrows that are 1.2 chi wide and 3 cun deep. Two rows of seeds are sown in each furrow, the two rows being 4 cun apart and the furrows being 8 cun from each other. The seeds are covered with 3 to 4 centimeters of soil. The calcium superphosphate is air dried, pulverized, sifted, and blended with the ammonium bicarbonate and a vibrating fertilizing device spreads the mixed fertilizer along the sides of the two rows of seeds in the furrow, 2 to 3 centimeters apart. When sowing is done, the soil is rolled to bring up soil moisture.

The second kind is the furrow seeding method used in places like suburban Beijing. On the front of the seed sowing machine is mounted six boot-shaped spades that do the furrowing, and a single disc double row comination furrowing device follows along the furrow to sow the seeds. The furrow is 1.2 chi wide, and two rows of seeds are sown in each furrow, the rows being 3 cun apart and the furrows being 6 cun from each other. Alternatively furrows may be 6 cun apart with a single row of seeds being planted in each furrow. An outside trough rotary fertilizing device spreads a flow of nitrogenous fertilizer such as urea or ammonium sulfate at a maximum 45 jin per mu. It cannot spread calcium superphosphate. Behind the machine is a cast place-like circular rolling device that flattens the furrows.

The third kind is a furrowing machine attached to a hand tractor that has been promoted in Shaanxi Province. It opens six furrows at one time, each of them 18 centimeters wide. Mounted on the furrow sowing machine is a fertilizer bin and a seed bin. The fertilizer bin bholds pulverized calcium superphosphate. Nitrogenous fertilizer is mixed with the seeds in the seed bin, and is spread simultaneously with the seeds. After sowing is done, the soil is compacted. When fertilizing (calcium superphosphate being applied to a depth of a 8 centimeters), both the seeds and the nitrogenous fertilizer are sown to a depth of 3 to 4 centimeters after which the soil is compacted. All four operations are completed at one time.

Cautions

(1) Furrowing and sowing of seeds cannot be readily separated, particularly in drylands. Practice has shown that a combination machine that furrows, fertilizes, sows, and compacts in one continuous operation is best.

(2) Furrow-sown wheat fields are easily prone to burial under windblown sand and watering of silted furrows may press down on tillers causing insufficient spiking per mu. Care should be taken to increase the amount of seeds sown to enlarge the number of plant colonies in order to assure a sufficient number of spikes.

(3) In order to increase the soil utilization rate, in field plots that are relatively fertile furrow width should be increased so that two rows may be planted in each furrow.

(4) In saline-alkaline areas, after furrow-sowing has been completed, compacting of the soil should not be done nor should the soil be hilled up around plants.

REVISED FORMULA FOR CALCULATING SEED NEEDS EXPLAINED

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 9, 20 Sep 82 p 3

[Article by Chen Zhenming [7115 2973 2494], Xianning Prefecture Agricultural Institute, Hubei Province: "Correction of Quantities Needed for Seeding on Basis of Per 1,000 Seed Weight"]

[Text] In the course of experiments when quantities of seeds needed for the sowing of paddy rice and wheat had to be generally determined, the following formula was used:

$$\text{Actual Amount of Seeds to be Sown} = \frac{\text{Planned Amount of Seeds Sown (Jin Mu}}{\text{Cost of Using Seeds}}$$

with cost of using seeds = Degree of seed cleanliness x sprouting rate ÷ 100. The shortcoming of this formula is that is has not taken into consideration the different per thousand (or per hundred) weight of seeds for different varieties of crops, which varies greatly. As growing seasons and farming conditions change, for the same variety seed weights change correspondingly. For example, by using the above formula to calculate quantity of seeds to be sown, the weight obtained for large seeds may be right, but the weight obtained for small ones may be overly large. In order to increase accuracy of experiments, I worked out the following corrected formula based on the per thousand seed weight:

Planned Amount of Seeds to be Sown (Jin/mu) = Standard Quantity of Seeds to be Sown (10,000/mu) x per thousand weight x 2 ÷ 100.

Since the corrected formula divisor is 100, after multiplying the standard quantity of seeds to be sown (10,000 seeds/mu) by twice the per thousand weight of the seeds (or 20 times the per 100 weight of seeds) and moving the decimal point two places to the left, the planned amount of seeds to be sown (jin/mu) can be derived.

For example, in comparative experiments of certain paddy rice varieties, it was determined that for the seedling field the standard quantity of seeds to be sown was 4 million seeds/mu. For variety A, the per 1,000 weight was 30 grams, so the planned amount of seeds of that variety to be sown = 400 x 30 x 2 = 240.00 (jin/mu). For variety B, the per 1,000 weight was 25 grams, so the planned amount of seed worked out according to the formula was 200 jin/mu. For variety C, the per thousand weight was 20 grams, so the planned amount of seeds worked out by the formula was 160 jin/mu., After calculating the planned quantity of seeds to be sown according to the foregoing corrected formula, on the basis of seed use cost the actual quantity of seeds per mu can be derived. For dryland crops, in addition to these calculations, it will also be necessary to estimate the field sprouting rate in order to determine the actual quantity of seeds to be sown per mu.

DOUBLE-CONTRACT ECONOMIC SYSTEM

HK111126 Beijing GUANGMING RIBAO in Chinese 31 Oct 82 p 3

[Article by Zhang Guangyou [1728 1684 0645]: "A Probe Into the Trends of Developing the 'Double-Contract' Responsibility System"--passages within slantlines published in boldface]

[Text] Since the 3d plenary session of the 11th CPC Central Committee, our rural areas have generally established and perfected all forms of the production responsibility system. The enthusiasm of the masses of peasants has been aroused and a heartening picture of prosperity in our agricultural production has emerged. Through several years of repeated practice, contrast and selection, the double-contract responsibility system (the system of assigning the households full responsibility for task completion and the system of setting fixed output quotas for each household) now plays a leading role in China's rural areas and has become the principal responsibility system. According to incomplete statistics, the double-contract responsibility system is practiced in more than 70 percent of China's rural areas. In Guizhou, Gansu, Anhui, the Nei Monggol Autonomous Region, Fujian, Henan, Ningxia and Hunan, the system is practiced in more than 90 percent of their rural areas. Most of the households which practice the double-contract responsibility system practice the system of "assigning the households full responsibility for task completion" and this responsibility system is still developing in some provinces and regions. Thus the question of how this responsibility system developes in the future is one which attracts the attention of people.

//It Is Necessary to Clarify the Nature of the "Double-Contract" Responsibility System//

In order to clearly determine the trend of development for the "double-contract" responsibility system, particularly the trend of development of the system of assigning the household full responsibility for task completion, first of all it is necessary to clarify a condition, that is, the nature of the "double-contract" responsibility system. In October 1981, Comrade Hu Yaobang met delegates to the meeting on rural work in China. He said to them: "Our policy has not shattered the collective economy. Land, the most basic means of production, is still owned by the collectives. The contract itself tells us that the nature of the system of collective ownership is not changed. The peasant used to say 'distribute the land.' It is incorrect to say that the system of assigning the households full responsibility for task completion is to 'distribute the land and work on one's own'." A large number of facts prove that: The "double-contract" responsibility system is not to "distribute the land and work on one's own," it is not individual economy and it is absolutely different from the small-scale peasant economy before the liberation. It is a form of the responsibility system which suits the actual conditions of most areas in China and is well received by the masses of peasants.

But there are a few people who hold that "the 'double-contract responsibility system' divorces ownership from the right of use. Ownership no longer plays the decisive role. Thus the 'double-contract responsibility system' is in fact land distribution." Such views are of course not in accordance with reality. In production relations, the ownership of the means of production plays a decisive role, and there is no exception in any society. In a feudal society, ownership of the land belonged to the landlords. Land was rented by the peasants for cultivation and the right of use belonged to the peasants. In that case, can we say that the ownership of land did not play a decisive role? Our society is basically different from a feudal society, but the right of use is still not the same as ownership. Production brigades can still exercise their right of ownership and announce that fields under the system of setting fixed output quotas for each household are taken back or adjusted; the users of the land do not have the right to handle the land. No matter whether it is under the system of assigning the households full responsibility for task completion or under the system of setting fixed output quotas for each household, the land is still owned by the collective and not by individuals. There are still some who say that: "The system of public ownership of land cannot determine the nature of the 'double-contract responsibility system.' There are capitalist states which practice the system of state ownership of land, so can we say that this is a socialist feature?" Those who hold such views have forgotten the most fundamental presupposition that our country is characterized by dictatorship of the proletariat; they have forgotten that the problem we study is a problem of socialist China under the leadership of the communist party.

Of course, in implementing any responsibility system, it is inevitable that there will be all sorts of questions and there is no exception in implementing the "double-contract responsibility system." For various reasons, when some regions practice the "double-responsibility system," problems appear. For instance, disputes arise over the use of farm cattle and irrigation facilities, land being divided into extremely small pieces, machines not playing their roles, property of the collective not being well protected and the problem that the four kinds of households, which have martyr members, soldier members, overseas members and members in Taiwan, as well as the households enjoying the five guarantees are not well arranged. Attention should be paid to these problems. But we should see that the above problems are not the problems of the "double-contract responsibility system" itself, but are problems related to work. Exactly for this reason it is extremely necessary to combine ideology and understanding and improve and strengthen leadership in the process of implementing and perfecting the responsibility system in agricultural production.

//The Masses Decide Which Kind of Responsibility System They Will Practice//

There are many forms of the contract responsibility system which links remuneration to output and which is now being practiced in the rural areas. There is the system of setting fixed output quotas for each household, the system of assigning the households full responsibility for task completion, the system of assigning responsibilities to each laborer and linking remuneration to output, the system of assigning responsibilities to each group and linking remuneration to output and the system of specialized contracts. Sometimes several forms are practiced at the same time or they overlap each other. This is quite normal. But there are people who say that the system of assigning the household full responsibility for task completion is an "elementary" responsibility system and they suggested that the "double-contract responsibility system" be guided by the system of "setting a fixed output quota for each laborer."

I think that whichever responsibility system we choose, we should not proceed from such abstract terms as "high-level" or "elementary," but we should see whether the form suits local conditions and the experience of the masses. As long as the form suits local conditions, promotes production development and is welcomed by the majority of the people, then this responsibility system is suitable as far as the place is concerned. On the contrary, if there is a responsibility system which many people hold is of an extremely "high level," but is not suitable for the place, harmful to production development and not accepted by the majority of people, then such a responsibility system should not be adopted. Just as people said in the rural areas in Henan: "Whether a form is good, the stomach indicates it, whether a form is elementary or of a high level, the judgment is based on the increase in production."

Then on what do we base deciding what form of responsibility system should be adopted? To sum it up, there are two points: First, proceed from reality, suit measures to local conditions and adopt whichever responsibility system we find suitable; second, let the masses of peasants have the right to choose and decide. In the process of investigation, we deeply felt that the adaptability of various forms of the responsibility system had the nature of an objective law which did not change according to people's will. There is process in which the adaptability of the responsibility system is verified by practice and observed, contrasted and selected by the masses. Leaders at all levels should avoid by all means subjectively and one-sidedly pursuing certain forms and should sincerely give the masses the right to choose. China is a country with a vast territory, and because natural conditions and economic based are not the same in all places, it is unrealistic to seek uniformity. Unhealthy results will be produced if we cut ourselves off from the masses and reality and blindly pursue the so-called "high-level" forms.

It is necessary to point out that if we take the responsibility system of assigning the households full responsibility for task completion as the most elementary form, we will come to the necessary conclusion that: The "double-contract responsibility system" is only an "expedient measure." We should admit that: At the present stage, the "double-contract responsibility system," particularly the system of assigning the households full responsibility for task completion, is a better responsibility system under the Chinese way of socialist agricultural management. Because compared with other responsibility systems, "the benefits are most direct, responsibilities most concrete and method most simple." This form suits the economic and natural conditions of most places in our country; in a certain sense, this form is an important measure of business management which our country has discovered through repeated practice and by paying a price on its way to collective agriculture. On the one hand, it has promoted the superiority of the collective economy, and on the other hand, it has fully aroused the enthusiasm of the masses of peasants and has solved a fundamental problem in collective business management that has not been solved for a long time.

//It Is Necessary to Stabilize and Perfect But Do Not Help the Shoots Grow by Pulling Them Up//

We should be positive that the "double-contract responsibility system" has a broad mass base and that it has strong vitality. But faced with the present situation of the "double-contract" responsibility system, it is necessary to make a concrete analysis. Judging from the actual situation in many places, since the "double-contract" responsibility system is practiced for a very short time and people have no experience, there are many practical problems which must be solved as soon as possible. For instance, the problems of how to unify planting plans, how to fully promote the roles played by the existing irrigation conditions and the grand-sized agricultural machines, how to make arrangements for the livelihood of the "households enjoying the five guarantees" and do subsidy work for the families of martyrs and soldiers, how to make arrangements for surplus manpower, how commercial undertakings can adapt to the rural areas and so on. Thus, to solve the problems which will surface after the "double-contract" responsibility system is put into practice and to continuously consolidate and perfect the system through practice is a central link of rural work at the present stage. The view that after the "double-contract responsibility system" is put into practice the peasants will have had initiative in production, that the peasants' enthusiasm will have been aroused and that it will no longer be necessary to strengthen leadership are extremely erroneous and harmful views.

Attention should be directed to the fact that there are people who think that under the "double-contract" responsibility system, the household is taken as a unit in its management, that it is an "all-round but small" form and that it is not advantageous to large-scale socialist production. They suggest we should strike while the iron is hot and put "specialized integration" into practice as soon as possible. How should we look at the so-called "all-round but small" system which takes the household as its unit? I think that first, we should see that it is suitable for a majority of the existing economic conditions and the level of business management in China at the present stage. Planting is the principal feature of agricultural production. The system with the household as its unit of management suits the characteristics of agricultural production and meets the demands of the masses of peasants. It should be clarified that the size of the production organization and the number of people who work together do not indicate the level of advance of production relations and the level of labor efficiency. In China, the size of the population is large while there is limited cultivated land, and it is necessary to practice a high degree of intensive management in agricultural production and do something in intensive cultivation. Of course, with development in production, the "double-contract" responsibility system may take the road of "specialized integration." But judging from the majority of production brigades which practice the "double-contract" responsibility system, we do not have the conditions necessary for "specialization" and "integration." A healthy and perfect stabilizing stage is necessary. Since the movement to organize cooperatives, there have been many policy changes, and the masses of peasants doubt the party's policies. At present, in places where the "double-contract" responsibility system is practiced, the masses are afraid of policy changes. If we do not proceed from the actual situation and put forward the slogan of "specialization" and "integration" when it is still early or in an improper manner, we will harm the stabilization and perfection of the "double-contract" responsibility system. Historical experience has proven that an important economic reform requires a long period of stabilization. We should learn the painful historical lesson and avoid by all means committing the foolish act of helping the shoots grow by pulling them up and avoid being over-anxious for quick results.

PRC'S WANG WEI EXPLAINS FOOD HYGIENE LAW

OW150351 Beijing XINHUA Domestic Service in Chinese 1411 GMT 12 Nov 82

[Text] Beijing, 12 Nov (XINHUA)--Explaining the draft PRC Food Hygiene Law at the 25th meeting of the 5th NPC Standing Committee held here today, Vice Minister of Health Wang Wei said that the draft law was written at a time when the whole country was implementing the PRC food hygiene control regulations promulgated by the State Council in 1979, as well as other food hygiene laws and regulations, after summing up the experiences and lessons of the past 30 years and more in connection with the supervision and control of food hygiene and also relevant existing problems, and after studying the food hygiene laws and regulations of a number of countries.

He said that drafting the law began in April 1981. Since then, the Ministry of Health has held more than 20 investigation and discussion meetings, and copies of the law have been distributed to the health and other departments concerned in various provinces, autonomous regions and municipalities directly under the central government, as well as to the concerned ministries and commissions of the State Council in order to extensively seek their opinions. More than 1,400 suggestions have been received, and the law has been revised more than 10 times. The general concensus is that promulgation of the Food Hygiene Law is absolutely necessary. The draft law was approved by the State Council at its routine meeting held on 6 November 1982.

Wang Wei said: The Food Hygiene Law has 45 articles in 9 chapters. Its main contents are: More specific regulations for food production, materials and vessels used for transporting food, food additives, materials and tools used for food packing and the management of equipment; explicit provisions requiring all production management departments and the units under their authority to be responsible for their own food hygiene and safety and to establish hygiene control and inspection organs; provisions on the adoption of a state system for supervising food hygiene and on fixing the responsibility of food hygiene supervisory organs and that of the personnel therein; and provisions on fixing the legal liabilities of those who cause harm or damage in violation of this law, aimed at protecting the interests of the people.

Wang Wei said: Since the founding of New China, satisfactory progress has been made in food hygiene work. However, the decade of domestic turmoil seriously disrupted this work. In addition, it has failed to catch up with the different ways of operating production. With the development in industry, agriculture and other fields, more possibilities exist for contamination of foodstuffs. This has caused food hygiene to deteriorate, and some cases have even posed a threat to the people's health and life and have adversely affected the four modernizations.

He said that patriotic health movements, launched since the founding of New China, have played a role in improving food hygiene. After the promulgation of the law, it is still necessary to strengthen the patriotic health movement. He suggested that patriotic health movement committees at all levels should continue to organize the masses for this purpose, to pay attention to propaganda and education on the legal system, morality and knowledge concerning food hygiene, and employ the means of inspection, appraisal, criticism and commendation to inspire the departments and units concerned to conscientiously implement the Food Hygiene Law.

RURAL AGRICULTURAL RESPONSIBILITY SYSTEM PRAISED

HK161230 Beijing GUANGMING RIBAO in Chinese 7 Nov 82 p 1

[Commentator's article: "The Agriculture Production Responsibility System is Created by Peasants"]

[Text] From today on this newspaper will publish a series of reports on how the production responsibility system known as "big contracting" is carried out in Chuxian Prefecture of Anhui Province. The great changes over the past 4 years since the "big contracting," or the production responsibility system of contracting production quotas to peasant households, was put into effect have convincingly proved that the production responsibility system has strong vitality and the development of agricultural production is still in the ascendant.

Do the production responsibility systems of various forms drop from the skies? No. Are they innate in people's minds? Again, no. It is the masses of peasants who created these systems in practice. For a long time in the past, affairs in China's rural areas were always tackled with the methods conceived and enforced by the authorities from one level to another. Peasants had no say in these affairs but could only act according to the directives issued by the authorities. The peasants' enthusiasm was thus greatly sapped. This was an important reason why China's agricultural production grew slowly. In the wake of the 3d plenary session of the 11th CPC Central Committee, the peasants emancipated their minds and took the lead in front of the people of the whole country. They eagerly demanded a change in the previous form of organizing production which was characterized by the rigid concentration of management, labor and distribution. They called for blazing a new trail which is suited to the characteristics of agricultural production and the reality of China's rural areas by shaking off the shackles of "leftist" ideology, old conventions and the previous rigid patterns under the guidance of the line set by the 3d plenary session of the 11th CPC Central Committee. It is under these circumstances that the various production responsibility systems of contracting production quotas to peasant households arose. As a result of this practice, this creation by the peasants has brimmed in the rural areas with vigor and vitality. Production has developed and peasants' mental attitude has also been greatly changed. Lenin said: Living creative socialism is the product of the masses themselves. This truth of historical materialism has now once again been proved in China's countryside.

Having been educated by the communist party for a long time, the Chinese peasants are new peasants [words unclear] to take the road of socialist cooperative economy. Through the comparison between the new and the old societies and from their personal experiences, they have clearly realized that the road of socialist cooperative economy is a broad road which can lead them to opulence. But how should they advance along this road? The practice followed since the 3d plenary session of the 11th CPC Central Committee has shown: 1) We should let peasants take this road by themselves. No person can do this on their behalf by enforcing administrative or other mandatory measures; and 2) we should let peasants gain real economic benefits in a way suited to local and current economic conditions. Matters which are economically impracticable are always refused by the peasants. The violation of the peasants' interests is to divorce the peasants from reality.

Does this mean that the party's leadership can be abandoned? No. It is obligatory on the party to show respect for the creative initiative of the masses when it is wielding its leadership. The party should seriously sum up the experience of the masses and popularize it. The fact that the production responsibility system can play a great role, from its emergence to universal introduction in the vast rural areas, has shown the importance of the party's leadership. Our party's traditional work method of "from the masses to the masses" is precisely reflected in being good at summing up the experiences gained by the masses and seriously popularizing them. It is a pity that for a fairly long time in the past this traditional method and style of work were cast aside due to the influence of "leftist" ideology. In the wake of the 3d plenary session of the 11th CPC Central Committee, party organizations and rural cadres at all levels restored and carried forward the party's good tradition of seeking truth from facts and practicing the mass line. They timely perfected and popularized the production responsibility system created by the peasants. Only thus can such a good situation emerge in the rural areas today.

In order to lead and educate the peasants, it is necessary to first learn from the peasants. Today's peasants are no longer the same as the peasants in the past. Now they have broader vision. They have become laborers in a socialist cooperative economy and are greatly different from the individual peasants in the former era of a natural economy. They have a vast reservoir of creative power. They can certainly break through the fetters of "leftist" ideology and open up a socialist road with Chinese characteristics in China's rural areas. Get yourself moving and go among the peasants, you will sweep all doubts and misgivings from your mind. The great prospect of China's agriculture developing with huge momentum will present itself before your eyes.

ABANDONMENT OF CONTINUOUS RICE, WHEAT CROPPING URGED TO INCREASE YIELDS

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 9, 20 Sep 82 pp 17-18

[Article by Xu Huandou [1776 3562 2435], Fengtai County Farming and Forestry Bureau, Anhui Province: "Ways to Solve the Longstanding Fluctuation in Yields from Continuous Rice and Wheat Cropping"]

[Text] Fengtai County is located at 32° 43' north latitude, which analysis of light, temperature, water, and soil ecology shows to be suitable for paddy rice and wheat production. Since 1970, as farmland water conservancy conditions have improved, the irrigated area increased, new superior varieties produced steadily, and chemical fertilizer increased year by year, the country CPC committee has proceeded from realities to propose a production program of "directing the main attack on wheat while expanding paddy rice," which has brought about very great growth of grain production. In 1981, as a result of diligent implementation of the spirit of the Third Plenary Session of the 11th Party Central Committee and institution of different forms of responsibility systems linked to output, wheat and rice output increased. Statistics show that yields from 553,000 mu of wheat were 307 jin per mu, and from 249,000 mu of paddy rice, 743 jin per mu. Furthermore there were some production brigades that produced 500 jin per mu of wheat and 1,000 jin per mu of rice. Nevertheless, we discovered that in some places that have long practiced continuous cropping of rice and wheat, output has fluctuated without moving ahead; costs have become increasingly high; and some problems urgently await solution without which further increases in grain output will be impaired.

Major Problems

(1) High yields for the first several years with yields per mu fluctuating after 6 years of continuous cropping. (Table 1)

Table 1. Rice and Wheat Output Statistics for Xuqiao Production Brigade, Madian Commune

表1 马店公社徐桥大队稻麦产量统计

作物种类 (b) / 年度 (a)	小 (c) 麦		水 (d) 稻	
	面积 (e)(亩)	单产 (f)(斤)	面积 (e)(亩)	单产 (f)(斤)
1970—1973	3,500	200—250	240	1,000—1,100
1974	3,560	250	485	850
1975	3,670	310	1,250	839
1976	3,760	350	1,400	600
1977	3,155	180	2,050	782
1978	3,670	320	1,830	770
1979	3,908	368	2,600	870
1980	3,750	310	3,500	551

(a) Year
(b) Crop
(c) Wheat
(d) Paddy Rice
(e) Area (Mu)
(f) Yield Per Mu (Jin)

A look at Table 1 shows that for the first several years after improvements in water facilities had been made, rice yields stabilized at a general somewhat more than 800 jin per mu and wheat yields per mu also tended to rise. After 1976, however, not only were rice and wheat yields no longer consistent, but increasing yields also became difficult. Surveys show that right after ricefields were improved, only 50-60 jinof ammonium bicarbonate was required per mu for a harvest of 800 jin of paddy, and pesticide and fertilizer costs per mu amounted to 10-odd yuan. With the passage of time, however, quantities of ammonium bicarbonate and superphosphate fertilizer increased year by year, about 80 to 90 jin per mu of ammonium bicarbonate and 80 jin of calcium superphosphate per mu being applied. To maintain the 800 jin per mu yields, the ammonium bicarbonate requirement is now between 150-200 jin per mu, and even so it is difficult to get 800 jin per mu of paddy, while both pesticide and fertilizer costs have increased tremendously.

(2) Gradual increase in soil alkalinity, decrease in potash content, and serious imbalance in proportions of nitrogen, phosphate, and potash. A survey done at 73 places in 1980 showed only 16 having a pH of 6.5-7.0, 16 having a pH of 7.0-7.5, 10 having a pH of 7.5-8.0, 19 having a pH of 8.0-8.5, and 12 having a pH higher than 8.5. Obviously the pH of some ricefields was greater than the 6.5-7.0 value deemed suitable. Even though the organic content of rice paddy soil was high, the proportions of quick acting nitrogen, phosphate, and potash were seriously unbalanced, a mutually restrictive situation taking place (Table 2). Everywhere paddy fields were potash deficient.

Table 2. Fertility of Clay and Sandy Paddy Soils

Survey Site	Organic Value (%)	Effective Nitrogen (ppm)	Quick Acting Phosphate (ppm)	Quick Acting Potash (ppm)
Shankou Tenth Brigade. Sandy Soil	0.60	5.9	3.4	98.0
County Agricultural Institute Paddy Clay	1.75	6.8	7.8	70.3

(3) Irrational crop patterns for paddy and wheat varieties with prominent seasonal conflicts. As a result of the high yields of hybrid rice in the current season in recent years, some peasant households are concerned only with the present season and unconcerned about the following season. More than 80 percent grow hybrid rice, so this means difficulties for directing the main attack on wheat. Wangyu Production Brigade in Baikuang Commune grows 1,200 mu of paddy rice including 1,140 mu of Shanyou No 3 and 661 for which the growing season is long. This delays the sowing of wehat. On 20 November the Production Brigade started to plant 200 mu of wheat, 700 mu less than in former years.

(4) Growing of a few superior rice and wheat varieties, which provide little potential for increased yields. Survey has found that in most places the paddy rices of choice are Nanjing No 11 and Zhenzhuai. For wheat they are 7023, Fengtai No 3, and Taishan No 1. These have been planted for a long time, and their yields per unit of area are not high. Ever since 1974 the county stock varieties rice farm has stuck to the production of Nanjing No 11 rice and 7023 wheat. Wheat yields are slightly more than 400 jin per mu, and rice yields are about 700 jin per mu. Though many measures have been taken, as a result of the long use of these two varieties it has been very difficult to increase yields per unit of area.

In addition, many years of continuous cropping of rice and wheat have made the soil's cultivated layer become shallow, the soil become sticky, the time when plowing can be done short, and caused deterioration in the soil's physical structure, problems urgently requiring solution.

Means of Solution

(1) Focusing on the overall situation in rational planning of the succession of crops. Rational planning of the succession of crops would not only assure yield increases for any given season, but would also mean increased yields season after season, and would be extremely beneficial in reviving and increasing soil fertility. Places that have continuously cropped rice and wheat for 4 long time could, while increasing yields per unit of area and without any decrease in total output, expand the growing of soybeans, peanuts and such pulse crops as well as rape, green manure, and cotton. Rotational cropping of the soil as wetland, and drylands would be remarkably beneficial in improving the soil's physical structure, in reducing the incidence of diseases, insect pests, and weeds, and increasing crop outputs. Ther should be planned step-by-step crop rotation.

(2) Rational choice and matching of superior varieties and following along in the growing of a certain superior variety for a long period of time does help one figure out the characteristics of varieties so as to be able to take corresponding action to increase yields per unit of area; however, because of the amounts of single nutrients drawn from the soil, the soil becomes deficient in its principal elements and reduced yields result. Under these circumstances, a change of superior varieties can bring immediate increases in yields. For example, some of the production brigades in Xialiang Commune grew Nanjing No 11 for a long time obtaining yields of from 700 to 800 jin per mu. In 1981, the brigade promoted hybrid rice for yields averaging about 1,000 jin per mu, which was from 200 to 300 jin per mu greater than for Nanjing No 11. Therefore, places having the water, fertilizer, manpower, and draft animals might start with an expansion of hybrid rice to increase their rice yields, and go on to cut back appropriately on the area sown to late wheat, increasing the area planted to rape for bumper harvests of both grain and oil.

Different areas with different levels of production and different peasant households may also use a different direction of attack on the problems of rice and wheat production; they should not practice arbitrary uniformity. In the attack on wheat, for example, they should select either a winter or semiwinter variety for more than half their crop, planting the remainder to spring varieties. Hybrid rices requiring a long growing season and variety 661 can be planted on 20 to 30 percent of the area, with rice varieties having a short growing season, such as Nanjing No 11, being grow on 70 to 80 percent of the area so that it can be harvested early and the fields cleared for the succeeding crop of wheat. Conversely, if mostly rice is to be planted, it should be hybrid rice or variety 661 planted on 60 to 70 percent of the area in order to get high rice yields. However, no matter whether the main attack is directed against rice or wheat, there should be no standardization of either the wheat or rice superior varieties grown. Fascination with anything can bring great losses.

(3) Promotion of return of stalks and stems to the fields to nurture soil fertility. In places where conditions permit, return to the fields of stalks and stems, or cutting the rice and wheat higher to allow more straw to remain in the fields should be vigorously promoted, so that they can be plowed under to fertilize the fields. This can both increase the soil's organic content and regulate the ratio of carbon to nitrogen in the soil, and can improve the soil's physical structure so that the soil can be plowed for a long period of time. By leaving in the fields 200 jin per mu of rice and wheat straw, the soil's organic content can be maintained with no dramtic decline.

(4) Change in farming methods, and striving to plant on time. On-time sowing is a prerequisite for sturdy seedlings that develop early. In order to solve the conflict between seasons resulting from the continuous cropping of rice and wheat, some changes in farming methods should be taken in hand. Even while the wheat is being harvested, plowing should begin, the soil turned to a good depth and sunned. Then the fields should be manured, water returned to them, and rice planted. After the rice crop has been harvested, if time is extremely short, sowing may be done after shallow plowing, rotary tilling, and fine raking. Experiments at many places during 1980 have shown that when wheat is sown after rotary tilling of fields from which rice has been harvested, not only do the numbers of basic seedlings increase and seedlings grow evenly in height, but ripening occurs 1 to 2 days early, spikes are large and grains numerous, and yields increase by about 10 percent. In addition, obtaining consistently high rice and wheat yields requires solution to technical problems of sparse sowing for sturdy seedlings, correct understanding of the insect pest situation, prompt prevention and control of crop diseases and insect pests, scientific use of water, sensible fertilization, and cultivation to get rid of weeds.

BRIEFS

WHEAT SOWING--By 26 October Anhui Province had completed more than 70 percent of its wheat sowing task. The acreage sown was 5 million mu more than in the same period last year. Before cold dew [the 17th solar term], Suxian Prefecture had sown wheat on 1 million mu. By frost's descent [the 18th solar term], it had basically completed its autumn sowing tasks. Chuxian Prefecture has sown 480,000 mu more wheat than last year. [OW301417 Hefei Anhui Provincial Service in Mandarin 1100 GMT 27 Oct 82 OW]

FLOOD VICTIMS--According to an ANHUI RIBAO report, the Anhui Provincial Government and other provincial authorities concerned organized 24 cadres into 8 groups and separately sent them, on 3 November, to Huaibei Municipality, Yingshang, Funan, Linquan, Xiao, Shou, Huaiyuan, Fengtai, Quanjiao and Huoqiu counties, which were seriously hit by floods and waterlogging, to solve pressing food and housing problems for victims there. Every cadre in the inspection groups was required to carry out his job earnestly and to accomplish the task by 22 November so that victims could spend the winter safely. BRIEFS

MARINE FISH-FARMING--Fuzhou, 25 Oct (XINHUA)--Output from marine fish-farming in Fujian Province during the first 9 months of this year exceeded 2,356,000 dan, topping last year's total annual output. Some 50,000 mu of laver and over 100,000 mu of oyster and clams remain to be collected. This year, the province has 380,000 mu of marine fish-farming areas, 10 percent larger than last year's. The province's output of laver and shellfish respectively accounts for 80 and more than 50 percent of the nation's total output. [Beijing XINHUA Domestic Service in Chinese 25 Oct 82 OW]

SEA FISH FARMING--Fujian Province's rapid development in marine fish farming since the 3d plenary session of the 11th CPC Central Committee has received favorable comment from representatives of fraternal provinces and municipalities and leaders of the Ministry of Agriculture, Animal Husbandry and Forestry attending the National Sea Fish Farming Work Conference now in session in Fuzhou. As of 1981 the province had 420,000 mu of marine fish farming areas, up from 320,000 mu in 1978, an average increase of 7.7 percent a year. From January to September this year, the catch exceeded the total catch of 1981. Per capita income in the fishing areas in 1981 was 230 yuan, doubling the 1978 figure. GANSU

BRIEFS

GRAIN PRODUCTION FORUM--Yesterday the Gansu Provincial Government held a forum in Zhangye on the development of grain production in the Hexi area. This forum discussed and formulated measures to speed up the building of a commodity grain base in the Hexi area. The Hexi corridor in the province is a newly-developed commodity grain base. Since the founding of the country, some 3 million peasants in the Hexi area have persisted in building water conservation projects, leveling fields, improving soil, planting trees and popularizing and applying advanced agricultural technology and measures so that the natural outlook, fundamental conditions for agricultural production and social economic situation have greatly changed. At present, the Hexi area has built 146 medium-sized and small reservoirs, sunk some 24,000 motor-pumped wells and electrically-operated wells, repaired and built channels, some which are 12,000 km long, and expanded irrigated fields by some 3.7 million mu. In the Hexi area, total output of grain in 1980 was some 2.68 billion jin more than in 1979 and the average per mu yield increased from 148 jin to 456 jin. Since 1975, the amount of grain supplied by the Hexi area to the state per year accounted for more than half of the amount of grain supplied by the whole province to the state. The Hexi area has reaped a bumper grain harvest again this year and its total output is 20 percent more than last year. The Hexi area has supplied more than 900 million jin of commodity grain to the state. [HK271418 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 21 Oct 82 HK]

HEXI AREA FORUM--The Gansu Provincial Government held a forum in Zhangye on the development of grain production in the Hexi area. The forum discussed and formulated the target of struggle for building the Hexi commodity grain base. In accordance with the target of struggle, the average yearly output of grain in 3 years is 3 billion jin and total output of grain by the year of 2000 amounts to 6.1 billion jin; total agricultural output value will increase from 900 million yuan to 3.6 billion yuan; the amount of commodity grain supplied to the state will increase from 890 million jin to 2.5 billion jin; the average per capita income will increase to 600 yuan. To achieve this target of struggle, the forum decided to take the following measures: 1) it is necessary to persist in the socialist orientation, continue to emancipate the mind, seriously perfect the rural production responsibility system and arouse the enthusiasm of the collectives and individual commune members; 2) it is essential to persistently do well in farmland and water conservation construction, further improve fundamental agricultural conditions and strengthen irrigation management; and 3) it is imperative to vigorously popularize advanced agriclutural science and technology and transform the farming system. [Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 26 Oct 82 HK]

BRIEFS

HAINAN SUGARCANE PRODUCTION CONFERENCE--The Hainan Regional Administrative Commissioner's Office recently held a conference on sugarcane production in Haikou. A total of 140 people attended the conference including all county CPC committees' deputy secretaries and county vice magistrates in charge of industry and communications, chairmen of all county economic committees and responsible persons of all sugar refineries. The conference noted: Due to the implementation of the policy on purchasing sugarcane since last year, our region's peasants' enthusiasm for promoting sugarcane production has been mobilized. Sugarcane production this year and next year will be higher than ever. This will lay a good foundation for opening up new prospects for our region's sugar industry. SUCCESS OF FERTILIZER EXPERIMENTS REPORTED

Shijiazhuang HEBEI RIBAO in Chinese 18 Sep 82 p 1

[Text] Most recently this reporter learned from related departments of the province that the experimental application of nitrogen-phosphate compound for wheat in the Heilonggang Prefecture of the province produced obvious results. Under this year's persistent drought condition, the 450,000 mu of wheatfields in the experimental area produced a general yield increase. The average unit yield reached 251 jin/mu, 81.85 jin/mu higher than the control (no phosphate application). The yield increase was 65.3 percent.

Aiming at the problem of low and unstable wheat yield of Heilonggang Prefecture, in the autumn of last year, the centers of agricultural science and their technicians of the five areas of Longfang, Handan, Xingtain, Hengshu, and Cangzhou established the Heilonggang Prefecture Wheat Development Research Cooperative Group for joint development of a research project with the use of nitrogen-phosphate compound as the base fertilizer with wheat as the major experimental crop. This was combined with the practice of trench seeding, increasing phosphorus and reducing water, promoting the weight of the grain, using inorganic to promote organic, breeding superior varieties, and high yield cultivation on thin land to form six experimental items of demonstration. The experimental fields, a total of 450,000 mu, were placed in the 9 counties of Dacheng, Wenan, Pingxiang, Julu, Nangong, Hengshui, Zaoqiang, Qingxian, and Hejian. Through survey and study, the scientists and technicians arranged a proper ratio of nitrogen and phorphorus according to the condition of phosphorus deficiency of each plot within these experimental areas and applied the compound as the base fertilizer for the wheat crop. Results of the experiment indicate that due to high nitrogen and phosphorus deficiency, especially phosphorus deficiency of the soils of the prefecture, when the nitrogen-phosphate compound is used as the base fertilizer, the fertility of the topsoil is improved, its ratio of nitrogen and phosphorus is properly adjusted, and strong seedlings may be obtained in the seedling process. Furthermore, the nitrogen and phosphorus contents of the soil may thus promote and supplement one another to raise the benefit. Phosphorus, in particular, acts to promote the early development of the wheat root system to cause the roots to be numerous and to stretch deep into the soil so that the wheat plants develop early and the prewinter seedling become strong. The drough-resistance, cold-resistance, saline and alkaline resistance, and dry and hot wind resistance of the wheat become better also. According to the experiment, compared with nitrogen alone, the nitrogen-phosphate complex adds 1.9 secondary roots to each wheat seedling before the winter and the dry weight of the root system is four times heavier to cause the total quantity of roots to be five to six times more [sic]. During the entire growth and development period, the wheat fields were irrigated only once. In the fields applied with the compound, the roots reached down to 130 cm in depth; in the fields applied with nitrogen only, the roots only reached down to 52.5 cm. Due to the flourishing development of the wheat root system, especially the radicles, the roots can absorb the moisture of the deep layers in the soil to supply the needs of the wheat plants to reinforce the plants ability to resist calamities.

Through the experimental demonstration, the scientists and technicians believe that the fast acting phosphorus content of the soil is the key to the effectiveness of phosphorus fertilizer application. According to the experiment carried out by the Hengshui area Agricultural Science Center, when the soil contains 9 ppm of fast acting phosphorus, for the application of each jin of phosphate fertilizer, the yield increase of wheat is 2.36 jin. On the basis of this data, when the fast phosphorus content is below 5-10 ppm, 80-100 jin of standard phosphate fertilizer may be applied. When the soil fast phosphorus content is 5-10 ppm, 40-60 jin of standard phosphate fertilizer may be applied. For a higher level of yield, the quantity of application may be suitably increased further. The method of application is found to be better as a base fertilizer than as a follow-up application, as a concentrated application better than as a scattered application. An application in a 3-4 cun depth of the soil is proper.

BRIEFS

THERMAL WATER RESOURCES--Scientists of the Research Institute of Hydrogeology and Engineering Geology of the Ministry of Geology and Minerals have carried out, from August 1979 to recently, a special subject survey and research project on the formation, distribution, and use condition of ground thermal water in Hebei Plain. The large quantity of data they have thus mastered proved that the ground thermal water resources in Hebei Plain are very rich and much can be done to develop this new source of energy. The hot water wells in Hebei Plain are distributed mainly in Xiong County, Gaoyang, Wuji, Ningjin, Xinhe, and Renqiu. Judging from the bore information the area with surface outpouring of ground thermal water may reach above 4,500 km^2. There are 150 plus wells, each producing above 100 m^3 of hot water a day. The temperature of the automatic flow water is generally above 60° C, with the highest reaching 110°C. This type of hot water is distributed at a regularity of 1,000-2,000 m in depth under the ground. Its pH is high, mostly alkaline. If it is used in cotton and wool textiles and in knitting and dyeing processes, the quality of the products may be improved. In agriculture, it may be used to build greenhouses to cultivate seedlings, vegetables, etc. This type of hot water also has good therapeutic effect on psoriasis, eczema, and arthritis. CIRCULAR ISSUED ON STOPPING RECKLESS TREE CUTTING

SK071022 Harbin Heilongjiang Provincial Service in Mandarin 2200 GMT 6 Nov 82

[Excerpts] On 3 November, the Heilongjiang Provincial CPC Committee and Government issued an emergency circular to urge party committees and governments at all levels and departments concerned to conscientiously relay and implement the emergency directive of the CPC Central Committee and the State Council on forbidding reckless lumbering.

The circular urges a general inspection of forestry policy and blows against those who illegally damage forests so as to effectively halt the evil trend toward recklessly felling trees. The circular urges:

1) The party committees and people's governments at all levels and departments concerned should conscientiously relay the emergency directive of the CPC Central Committee and the State Council among the masses in order to make it known to every household and to every person.

2) We must resolutely combat the phenomenon forest destruction. The propaganda departments at all levels should closely work in cooperation with leading party and government organizations to publicize the guidelines of the emergency directive of the CPC Central Committee and the State Council. Efforts should be made to whip up public opinion so as to consciously form a fine general mood of society among the people of the province to take good care of forests.

3) We must conscientiously implement the directive of the CPC Central Committee and the State Council that CPC committees and people's governments of counties with forests should be in charge of implementing the decrees for protecting forests.

4) All localities should conscientiously organize forces of forestry, local procuratorial, public security, procuratorial and court organizations to conduct a general inspection of forestry policy throughout the province.

5) Only the forests that are designated under the state or provincial plans may be opened up. Denuding of forests not covered by any plans must be resolutely forbidden.

6) We should firmly and successfully attend to forestry, stabilize mountain and forest rights and delimit private mountainous areas in order to develop the production responsibility system in forestry.

BRIEFS

NATURAL RESOURCES--More than 80 scholars, specialists, scientists and technicians in the fields of garden, forestry and agriculture were invited to a symposium 29 October in Yichun Municipality, Heilongjiang Province, to discuss the issue on rationally exploiting the natural resources of the greater and lesser Xing'an mountains. The symposium participants pointed out that some 16.7 million cubic meters of timber have been grown annually in the forest areas of these mountains, but some 25 million cubic meters of timber have been felled annually. At present, the province's comprehensive timber utilization rate is 23 percent. The growth rate of trees in these mountains is only 1.08 percent. If we increase the tree growth rate to 2 percent, the contradiction between tree planting and felling will be alleviated. Wang Jinling, deputy provincial governor, attended the symposium. BRIEFS

WHEAT SOWING--By 23 October, Henan Province had cultivated wheat on some 58 million mu, which was 15 million mu more than in the corresponding period last year. The province had fulfilled 90 percent of its wheat cultivation quota. The province has collected 250 million cubic meters of clay fertilizer and miscellaneous manure for wheat cultivation this year. There is an average of 4 cubic meters of clay fertilizer and miscellaneous manure for each mu. The meaees have bought 1.64 million tons of nitrogenous fertilizer, which are 380,000 tons more than last year. They have bought 1.57 million tons of phosphatic fertilizer, which are 610,000 tons more than last year. On average, about 50 jin of nitrogenous fertilizer and phosphatic fertilizer has been applied on each mu of wheat. All places in the province have bought some 700 million jin of superior wheat seeds and trained 1.68 million wheat technicians, 200 percent more than last year. BRIEFS

CATTLE EXPORT--The export volume of marketable cattle of Ju Ud League, Nei Monggol has been increasing year after year. Since 1978, the league has exported 26,100 head of marketable cattle to Hong Kong and Macao, earning 7.5 million yuan of foreign exchanges for the state. After the implementation of the party's economic policies for rural pastoral areas, the relevant departments of the league allocated special funds amounting to 390,000 yuan for the development of cattle raising. According to statistics, in 1981 the league exported 8,700 head of marketable cattle and in the January-July period of 1982, 6,600 head. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 16 Sep 82 SK]

SHEEP'S WOOL--Nei Monggol region reaped a bumper sheep's wool harvest in 1982, overfulfilling the annual state procurement target 4 months ahead of schedule. By the end of August, the region procured over 86 million jin of sheep's wool, an increase of 6.9 million jin over the 1981 figure, topping an all-time peak. During the January-August period, the fine hair sold to Beijing, Tianjin and Shanghai municipalities reached 23 million jin, up 5.8 million jin as compared with 1981. [SK180033 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 16 Sep 82 SK]

BEET OUTPUT--Nei Monggol region sowed over 1 million mu of beets this year. It is estimated that total beet output will surpass 1 million jin, up 20 percent over the previous record. Bayannur and Ju Ud leagues sowed 570,000 mu of beets this year. In addition, 87 percent of beet seedlings are kept in full stand and sugar content will be higher than that in 1981. [SK192314 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 18 Sep 82 SK]

BEET HARVEST--This year Bayannur League in Nei Monggol Autonomous Region reaped a bumper sugar beet harvest. According to statistics, the league's total sugar beet output this year is expected to reach 1 billion jin. The average per-mu yield showed an increase of 20 percent over 1981. [SK300243 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 26 Oct 82 SK]

AUTONOMOUS REGION INCREASE IN SUMMER GRAIN REPORTED

Yinchuan NINGXIA RIBAO in Chinese 18 Sep 82 p 1

[Text] This year the total summer grain production of the region reached 12.5 billion jin, an increase of 12.5 percent over last year's bountiful harvest. The wheat yield of areas irrigated by the water of Huanghe was a great deal higher, with a total production of 1.08 billion jin, an increase of 20.9 percent over that of last year. Due to a particularly severe natural calamity, the summer grain production of the mountainous areas was 17.7 percent less than the year before.

This year, the rural villages and the state-operated farms of the autonomous region implemented the post-Third Party Congress line, policy, and goal still further. The system of production responsibility was increasingly completed and perfected. Productive enthusiasm of farmers and state-operated farm workers was unprecedentedly high. The party organizations of all ranks took advantage of the situation and provided favorable guidance to help the cadres resolve the relationship between unity [unified leadership or planning] and responsibility [production guarantees.] Productive enthusiasm of the masses was encouraged while the merits of collective economy were also promoted. Meanwhile, the leaders and the agricultural technology departments also adopted various ways, geared to the new condition of the rural villages following the practice of the production responsibility system to carry out the work of extending agricultural sciences and technology. In all the counties of the Huanghe irrigation district, the acreage of superior breed wheat was greater than the year before and such techniques as timely seeding of proper amount of seeds, reasonable fertilizer application, timely irrigation, serious pest and disease control, and intensive field management were accomplished. In addition, the weather was relatively satisfactory to result in the great increase of unit yield. With the 53,000 mu additional summer grain acreage, the output of all the 11 counties (suburbs) was larger than that of the previous year. Of these counties, the yield increase of Yongning, Helan, Taole, Zhongwei, and Qingtongxia and the suburbs of Yinchuan City was more than 20 percent and that of Pingluo County exactly 20 percent. The yield of the suburbs of Shizuishan City and Zhongning County was more than 15 percent. The output increase of all the remaining counties was also more than 10 percent. At present, the cadres, commune members, and employees of the state-operated farms of the Huanghe irrigation district of the autonomous region are delighted with the great harvest of summer grains and are struggling for obtaining bountiful harvests all through the year. In the mountainous areas, the work of fighting natural disasters is proceeding in earnest.

CONFERENCE ON WINTER AGRICULTURAL PRODUCTION

HK080920 Xian Shaanxi Provincial Service in Mandarin 0500 GMT 7 Nov 82

[Text] Yesterday evening, the Shaanxi Provincial CPC Committee and the Provincial Government held a telephone conference on winter agricultural production and rat extermination. In his speech, Vice Governor Bai Jinian pointed out: At present, the central work of the rural areas in our province is that we must regard the spirit of the 12th party congress as the impetus and, while perfecting and promoting the agricultural production responsibility system, vigorously do well in grasping farmland capital construction and winter crop field management.

Bai Jinian said: With a view to further improving conditions for agricultural production and ensuring that grain output in the sixth 5-year plan period will exceed 20 billion jin and the average per capita output of grain by the end of this century will amount to 1,000 jin, farmland capital construction at present and in certain years in the future is a central task and we must persist in embarking on it for a long time. He demanded:

1. We must fully mobilize the masses; leaders must personally assume command; and tasks must be done and responsibility shouldered at all levels to ensure that over 30 percent of the labor force will take part in farmland capital construction.

2. In light of the different situations of various places, we must define the main direction of attack in each place. Sanyuan County must mainly harness small basins in connection with planting trees, growing grass and developing forage grass fields. At the same time, it must do well in developing drinking water projects for both human and livestock consumption. Irrigated areas must stress developing square fields with a network of forests and regard the irrigation conveyance system as the key point. We must step up repairs in areas seriously damaged by floods.

3. To suit changes in the forms of the production responsibility system, we must take such measures as are suitable to local conditions and have flexible and varied organizations and measures. Some places can implement the system of attending to farmwork while others can implement the system of assuming full responsibility for task completion or the system of

contract. Other places can also implement the cooperation system. However, we can by no means pursue equalitarianism or indiscriminately transfer resources.

4. We must resolutely implement the provincial government's circular and order on the strict prohibition of the sabotage of water conservation and water and soil conservation facilities.

Comrade Bai Jinian also demanded: At the same time, all places must step up winter crop field management and rat extermination. Responsible comrades of Liquan and Yanchang counties introduced their experiences in carrying out farmland capital construction. Comrade Yu Mingtao, Provincial CPC Committee secretary and governor, presided over the telephone conference.

BRIEFS

TANGERINE OUTPUT CONFERENCE--A conference of 12 provinces and municipalities--Gansu, Sichuan, Henan, Jiangxi, Hunan, Hubei, Anhui, Shanghai, Beijing, Zhejiang, Guizhou and Shaanxi--on tangerine production was recently held in Hanzhong, Shaanxi Province. Approximately 100 workers attended who are engaged in scientific research on and production of tangerines. They held that if we can select drought-resistant and superior quality tangerine varieties and pay attention to raising the level of scientific management, we can increase our output of tangerines. [Xian Shaanxi Provincial Service in Mandarin 0500 GMT 22 Oct 82 HK]

MEANS OF PRODUCTION--From January to September this year, the amount of money which peasants in Shaanxi Province spent on means of production amounted to 650 million yuan and was 16.5 percent more than in the corresponding period last year. They bought 1.01 million tons of chemical fertilizers, which was 27.5 percent more than in the same period last year; 722 large tractors, an increase of 50.7 percent; some 9,300 3-wheeled, motorized carts, an increase of 120 percent; and some 18 million medium-sized and small agricultural tools, an increase of some 10 percent. MASSES REASSURED ON AGRICULTURAL POLICY

SK080704 Jinan Shandong Provincial Service in Mandarin 2300 GMT 7 Nov 82

[Text] In publicizing the 12th congress documents, the Yidu County broadcast station has seized on the subject about which the peasants care most and stressed it as the main point. An investigative report conducted by the station before the 12th congress revealed that the issue about which the broad masses of commune members and grassroots cadres care most is whether the party's policy will change. To help them clarify the point at issue, the county broadcast station repeatedly beamed the portion of Comrade Hu Yaobang's report dealing with persistently implementing the agricultural production responsibility system on a long-term basis and gradually perfecting it. The station also broadcast many programs on supplementary lectures on studying the 12th congress documents and stabilizing and perfecting the production responsibility system. It also broadcast many articles by commune members and cadres on their study and understanding of the 12th congress documents in programs devoted exclusively to the study of the 12th congress documents, giving wide publicity to those examples of achieving prosperity through hard work and to units and individuals distinguished in promoting the spiritual civilization. Peasants in the county are, one after another, buying the means of production. In the past month the peasants have purchased 1,500 draft animals and 1,300 diesel engines, electrical machines and water pumps. Sales of cake fertilizer and chemical fertilizer have also increased markedly.

DEZHOU PREFECTURE READJUSTS CROP DISTRIBUTION

Beijing BEIJING RIBAO in Chinese 23 Sep 82 p 4

[Text] XINHUA Editors Note: The experience of realizing rapid yield increases of both grain and cotton in Dezhou Prefecture of Shandong Province is a new inspiration for us all. It presents us with a scientific attitude of persistent struggle in a realistic manner, with unshakable faith to march steadily forward. Under the guidance of the 12 great spirits the leaders of the party are guiding the masses of people to stride in vigorous steps up the terrace to reach the height of Taishan. In this manner, our goal of creating the new situation of socialist modernization construction will definitely be accomplished.

The Dezhou Prefecture of Shandong Province made reasonable adjustment in its crop arrangement. Attention was given to the merit of developing cotton production and at the same time, grain production was not neglected. In this manner, yield increases of both grain and cotton were achieved. Compared with 1978, the cotton acreage of the prefecture last year was 2.63 million mu larger to produce a total increase of cotton production of 3 million dan, an increase of more than 7-fold. The grain acreage was decreased 1.41 million mu, while the total grain production remained 390 million jin higher, an increase of 13.1 percent. The total production of summer grain of the prefecture this year was more than 300 million jin above that of the previous year, an increase of 20 plus percent. Cadres and members said happily that "Grasp the gold (grain), push the silver (cotton) up, life is getting more and more delightful."

Dezhou is an old cotton-producing area. After the Third Plenary Session of the 11th Party Congress, the crop arrangement has been readjusted to restore some cottonfields squeezed out by grain crops during previous years. With increased production of cotton, more and more cotton was sold to the state and the incomes of the collectives and the members increased year after year. Under this condition, the trend of contracting the grain acreage began to appear in some areas. The CPC of Dezhou and the executive office cooly analyzed the situation. They believed that Dezhou had a farming population of 5 million and the problem of food just could not be resolved on the basis of state supplies. Grain and cotton production just had to be taken into equal consideration to make a reasonable arrangement and to struggle for yield increases of both. Originally, Dezhou Prefecture planned an expanded cotton acreage of 170,000 mu. After the leadership was strengthened, the cotton production plan was readjusted realistically to 700,000 mu only, to increase 100,000 mu of grain acreage.

Dezhou Prefecture has a great deal of wasteland and alkalized land. In the process of expanding the cotton acreage, as much as possible they developed and used the waste and alkalized lands so as not to take over grainfields. In order to resolve the land competition between grain and cotton, wherever the condition permitted intercropping wheat and cotton was also actively extended in the prefecture. After the grain acreage was reduce, in order to guarantee grain production increase, Dezhou Prefecture adopted the method of using grain to guarantee cotton production and using cotton to promote grain production so as to guarantee yield increased of both grain and cotton. In these few years, cotton production was quickly established to increase the income of cotton farmers. The Dezhou Prefecture Committee and the executive office directed and organized the cotton farmers in a timely manner to transfer the bumper cotton harvest into a large quantity of chemical fertilizer, residue cake fertilizer, and capital to be invested in grain production. As the agricultural production system began to be extended, many communes and brigades of this prefecture adopted the method of separate guarantees for cotton and grain and in some communes and brigades, a tendency of competing for cotton contracts and unwillingness to take on grain contracts appeared for a while. The prefecture extended in a timely manner the method of mixing cotton and grain contracts by individual workers or households, effectively to insure the implementation of the grain production responsibility system. Last year, in the prefecture the per capita grain consumption was 670 jin and the per capita grain production was 446 jin. With the added grain production of the private plots, the per capita grain supply reached more than 500 jin.

After several years of readjustment, the ratio between grain acreage and cotton acreage in Dezhou Prefecture this year was 55:45. The prefecture committee and the executive office believe that the present ratio of grain and cotton has become reasonable and they have asked all areas to stabilize it on this basis. In the future, the traditional yield increase experience of the masses should emphatically be united with modern scientific technologies to strive for increasing the unit yield and to struggle for continuous yield increases of grain and cotton.

SOIL CONSERVATION WORK CONFERENCE ENDS 4 NOVEMBER

SK050956 Jinan Shandong Provincial Service in Mandarin 2300 GMT 4 Nov 82

[Text] The Provincial Water and Soil Conservation Work Conference concluded on 4 November. It pointed out that our province's water and soil conservation work is very arduous. Efforts must be made to control soil erosion as soon as possible and to do a good job on construction in mountainous areas in order to expedite the province's agricultural development. The conference was attended by responsible persons in charge of agricultural water conservancy work of various prefectures, municipalities and some counties, responsible persons of departments concerned, scientific research units as well as experts and professors of colleges and universities.

The conference noted that the water and soil conservation task of our province is very difficult. There are still 23,000 square kilometers of eroded areas in hilly sections that urgently need improvement. Of the initial 20,000 square kilometers of lands that have been improved, some have been damaged again. Those that have not been damaged again also need further improvement. The task of planting trees and grass to prevent windstorms and to immobilize shifting sands is still arduous for the province's 16,000 square kilometers of plains and windy and sandy areas. Therefore, controlling soil erosion as soon as possible, protecting water and soil resources, creating a good environment for production is of great significance in building mountainous areas, expediting the province's agricultural production and creating a new situation in all fields of socialist modernization.

The meeting urged all localities to take the guidelines of the 12th party congress as a guide, implement the guidelines of the fourth national water and soil conservation work conference, adhere to the principle regarding the work of water and soil conservation formulated by the State Council, which urges efforts to pay equal attention to preventing and tackling problems, to combine problem-tackling work with management, to suit measures to local conditions, to map out overall plans, to tackle problems comprehensively and to [words indistinct]. The meeting also urged efforts to continuously implement the guidelines of the provincial work conference on building mountainous areas. In carrying out water and soil conservation work in the days to come, we must lay stress on the following three points:

1. Actively improve vegetation. Prior to 1990, efforts must be made to plant trees on all lands that can be afforested and to plant grass in all places that need grasslands. Plains, and windy and sandy areas must complete the afforestation and grass-planting work 3 to 5 years prior to 1990.

2. Terraced fields must be built in mountainous areas so as to attain the demands of conserving water, soil and soil fertility.

3. Actively build projects to stop drifting sands from shifting into water areas.

In short, we must grasp the key points, tackle problems concerning water and soil conservation comprehensively, concentratedly and continuously and strive to basically control the province's soil erosion by the end of this century.

The conference stressed: The key to doing a good job in water and soil conservation work lies in leadership. Leaders at all levels must attach importance to the guiding principle, pay due attention to water and soil conservation work and grasp this work on a long-term basis and with good results. Efforts must be made to implement the regulations regarding water and soil conservation formulated by the State Council, map out good water and soil conservation work plans, do a good job in conducting scientific research and technical training work, arouse the enthusiasm of all quarters and upgrade the work on conserving water and soil in a down-to-earth manner.

BRIEFS

MECHANIZED FARMING--Various localities of Shandong Province have called in the service of farm machinery to accelerate autumn sowing. As of early October, 336,000 tilling and harrowing machines and 39,000 sowing machines had been utilized. Of the total farmland, 74 percent were tractor-plowed and 46 percent tractor-sown. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 26 Oct 82 SK]

WHEAT SOWING--By 27 October, Shandong Province had sowed 55.6 million mu of wheat, overfulfilling this year's autumn wheat sowing task. Linyi Prefecture had sowed 7.75 million mu of wheat by 27 October, overfulfilling plan by 1.2 million mu. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 27 Oct 82 SK]

WHEAT PLANTING--Jinan, 25 Oct (XINHUA)--Shandong, a major wheat area in China, has basically completed this year's autumn wheat sowing task. By 20 October, the province had planted 54 million mu, an increase of 3 million mu over the same period last year. Wheat sowing is continuing in many prefectures which try to expand their wheat area. The province's total wheat area is expected to reach 55 million mu this year. [Beijing XINHUA Domestic Service in Chinese 1154 GMT 25 Nov 82 OW]

BRIEFS

DIVERSIFIED ECONOMY—Shanghai's foreign trade departments have vigorously supported the suburban counties in developing diversified economy and increasing production to expand exports. This year, total volume of products from diversified economy procured by foreign trade departments reached 350 million yuan, which is 3 1/2 times the 1977 figure. These products will bring in more than $120 million in terms of foreign exchange and will add more than 35 million yuan to the state's revenues and profits. MEETING ON WATER, SOIL CONSERVATION

HK100337 Taiyuan Shanxi Provincial Service in Mandarin 2300 GMT 9 Nov 82

[Summary] The Shanxi Provincial Water and Soil Conservation Committee held a provincial conference on water and soil conservation in Taiyuan from 2 to 6 November. The meeting stressed: "In creating a new situation in water and soil conservation work in the province, we must: 1) vigorously popularize the experience of having households take contract responsibility for harnessing small river basins, and 2) resolutely curb destruction of forests and grassland and the reclamation of barren slopes."

Having households undertake contract responsibility for harnessing small river basins is a new thing that has appeared in the rural areas following the institution of the comprehensive contract responsibility system and a good way of speeding up construction in the mountain areas. Xinxian Prefecture has popularized the experience of a peasant household in this respect since July. In only 2 months or so, 41,700 peasant households in the prefecture have undertaken contract responsibilities for harnessing 6,800 small river and stream basins, covering a total area of 397,000 mu. Many places throughout the province are studying this experience.

The conference pointed out: In instituting this system, it is first essential to do a good job in planning. Various flexible measures should be adopted in light of local conditions.

The conference stressed: "At present there is serious destruction of forests and grassland and reclamation of barren slopes in many places in the province. Harnessing is carried out on the one hand and destruction on the other. In some places the destruction actually exceeds the harnessing. We must resolutely curb this situation and slam on the emergency brake. If we let it go on, the province's limited [words indistinct] resources will be seriously damaged."

Many of the participants said: "Many leading cadres have not regarded destruction of forests and grassland and reclamation of barren slopes as economic crimes. They just treat it as a measure for increasing grain production. Many leading cadres even take the lead in reclaiming the barren slopes. The state has now promulgated work regulations for water and soil conservation. In the future, leadership responsibility will be investigated for any failure to enforce them."

PRELIMINARY SUCCESSES IN HEXAPLOID COTTON HYBRIDS REPORTED

Beijing NONGYE KEJI TONGXUN [AGRICULTURAL SCIENCE AND TECHNOLOGY NEWSLETTER] in Chinese No 9, 20 Sep 82 p 2

[Article Li Bing Lin [2621 3521 2651], Zhang Xinrun [1728 2450 3387] and Wang Yun [3769 0060], Shanxi Agricultural University: "New Progress in Interspecific Hybridization Research on Asia Cotton and G. Bickii Cotton"]

[Text] Accompanying the need for development of cotton production, people have made higher and greater demands for cotton varieties. They have desired that varieties bred be high yielding and early maturing, have high fiber quality, be resistant in amy ways, highly resistant to diseases and insect pests, and such superior properties, while at the same time having the properties of seeds without glands [5177 7555] and plants with a high gland content so that cotton products will have all-around usefulness, production costs lowered and environmental pollution reduced. Because of the shortage of cotton germ plasm resources today, it is difficult to breed species with pronounced characteristics through the use of conventional cotton growing methods. Consequently, it is necessary to expand plasm resources for cotton breeding, artificially creating more and better breeding plasm. Use of remote hybridization methods to make new combinations from beneficial genes in wild growing cotton species and genes from upland cotton currently being farmed is a major way in which to realize the foregoing objective. Since 1965 when the world's first phenol-free cotton was bred until the present time, the numerous phenol-free dotton varieties that have been bred have not been promoted to wide area cultivation because of their proneness to diseases and insect pests. In 1965 Fryxell discovered that undomesticated G. bickii cotton had the special characteristic of delayed formation of oil glands and that the seeds contained no glands; however, the boll loculi had generating cells for oil glands, but only after the seeds has sprouted did the oil glands form. During the past 10 years and more, much research in this regard has been conducted abroad in an effort to transfer this trait to cultivated upland cotton varieties, without any success whatsoever. This trait was not found among the hexaploid (ADG) cotton bred from the hybridization of upland cotton and G. bickii cotton by Molamotuo [phonetic]. By way of exploring ways to breed varieties having seeds without glands and plants with high gland content, our thought was first to transfer this trait from G. bickii cotton to A or D chromosome cotton seeds, thereafter doubling the transferred hybrid chromosomes and then conducting further study of the possibilities for transfering this trait to domesticated upland cotton hybrids. First the results of research that had been done on the hybridization of Asia cotton and G. bickii cotton was used for briefing purposes as a way in which to provide cotton breeding workers a reference for use.

G. bickii cotton is a wild growing creeping cotton plant that grow in central Australia, $2n = 26$, its chromosomes belonging to C_4 of C group. Most recent research reports have additionally classed it as a new chromosome group G_1. The stalks and both sides of the leaves of this cotton variety are covered with fuzz (5000 - 6000 individual hairs/cm^2). Most of the leaves are rather small and ovular in shape. Ventilation and light penetration characteristics are very good Bracts are particularly small and stand out from plants, thereby reducing the contamination of cotton fiber with bract leaves that lowers cotton quality, which is a very fine trait. Plants have many branches, and have strong boll formation characteristics and a low rate of bud and boll drop; they are also early maturing drought resistant, disease and insect resistant, and fibers are fine and strong. Particularly because the seeds lack glands while the plants have a high gland content, these plants are an extremely valuable plasm resource in the breeding of cotton. Our hybridization work got underway in the school's hothouse in August 1980. Using the small black seeds of Asia cotton brought from the west as the female parent, and the wild growing G. bickii cotton as the male parent, much cross-pollinization was done during the period of vigorous flowering of plants. After removal of the male organs and artificial pollination, drops of gibberelin (GA) and methyl a-naphthyl acetate (NAA) were put inside the bracts to preserve the bolls. That year 6 zero generation hybrid seeds were obtained. Planted in early April 1981, two plants survived and began budding in July. Trait mutations were numerous and remarkable in the first generation hybrid plants. The plants looked like cedar trees and manifested the strong boll formation characteristics, the small leaves, the lack of compactness of bolls around bracts, and numerous characteristics of the male parent, while the cotton boll and numerous seed traits were close to those of the female parent (Asia cotton). Statistics derived from preliminary observation of 20 traits of the hybrids showed seven similar to the male parent's traits including color and luster of petals, and flowering characteristics. Three traits resembled those of the female parent including size of seeds and shape of bolls. There were six mutations that contained traits from both, and four other mutations. In order to enlarge the number of first generation hybrid plant colonies, we propagated 10 plants using asexual grafting, which were supplied as experimental materials for hybridization with upland cotton and for doubling of hybrid chromosomes.

A high amount of infertility existed in first generation plants resulting from the crossing of Asia cotton with G. bickii hybrid variety. After plants budded, within 2 or 3 days all the buds fell off the plants. After hormones were used to preserve the bolls (drops of gibberelin and methyl a-naphthyl acetate applied inside the bracts), though buds stopped dropping, once the cotton bolls split open, only a very small degenerate embryo was found within. Microscopic examination of pollen showed irregularities in size, most pollen being rather small and round in shape. No semicircular or short thick pollen was found. When stained with the reagent, benzidine methonaphtol (5114 0058 5143 3946 6055 1568], observation showed only 1.3 percent of the pollen to be alive, which explains why there was a high rate of infertility among male gametes in first generation hybrids, and this was the principal reason why the first generation hybrid plants did not form bolls.

In order to overcome infertility in first generation hybrids, we undertook a doubling of plant chromosomes. We used a solution of 0.2 percent cochicine and 5 percent dimethylsulfoxide at a temperature of 25°C to treat growth points on several different parts of plants for 24 hours. In April this year five bolls formed on branches whose chromosomes had been successfully doubled, and after all had been opened, 50 plump first generation seeds were obtained.

To summarize the foregoing, our research results showed that by using effective measures of sexual hybridization plus hormone treatment of matched plants of domesticated diploid Asia cotton and wild growing G. bickii, obstacles to their reproduction can be overcome and first generation hybrid seeds obtained. At the same time, by using cochicine to treat growth points on first generation plants, it is possible to restore their fertility and obtain plump F_1 generation seeds. Now we are in process of carrying out hybridization of upland cotton. The hybrids formed from corssing of Asia cotton with G. bickii cotton may supply the plasm resources needed for breeding early maturing, drought resistant, disease and insect resistant, fine fiber quality varieties that can be used in an all-around way for food, cotton, and oil.

'WEN WEI PAO' ON HU YAOBANG'S VISIT TO LIANGSHAN

HK170421 Hong Kong WEN WEI PAO in Chinese 17 Nov 82 p 3

[Report: "Hu Yaobang Visits Liangshan, Stresses Developing Animal Husbandry"]

[Text] Chengdu--Recently, not long after the convening of the 12th CPC Congress, Hu Yaobang inspected Dukou Municipality and Liangshan Autonomous Prefecture in Sichuan Province. During his investigation of the cadres and masses in Liangshan, Hu Yaobang discovered that to change the state of affairs in Liangshan, they should exert their superiority and the development of animal husbandry should be stressed. So as to enliven their thinking and broaden their field of vision, Hu Yaobang listed large number of facts, calculated many itemized accounts and repeatedly explained from north to south and from internal to foreign the great significance of conspiciously developing animal husbandry.

Hu Yaobang said: Recently, I made some investigations in the north. The income from four dairy goats is equal to the salary of a new university graduate. 6 jin of milk is equal to 1 jin of grain. If Liangshan Prefecture can breed 6 million dairy goats, this would be equal to 1 million dairy cows. They can then produce 2 million tons of milk a year, equal to 6 million jin of grain. This is a considerably figure. Milk and meat are the staple food in many countries at present. The Henggu (Monggol), Heiwuer (Uygur) and other minority nationalities of our country also take milk and meat as their staple food, so they are sturdy and strong. Our Yi and Han nationalities should also imitate them in this respect and gradually change the composition of our diet. There are more than 6 million mu of cultivated land in Liangshan Yi Autonomous Prefecture. The area of wooded and hilly lands, grassland and water is ten times more than the area of cultivated land. Therefore, it is quite obvious that we must proceed from this practice, carry out a combination of agriculture. forestry and animal husbandry, and raise the development of animal husbandry to a more important position. We must also be aware that this is a revolution in the agricultural sphere. Only by carrying on this revolution step by step for a decade or two can we have a radical change. Otherwise, if we insist on a single product economy grasping only the grain, ignoring the development of a diversified economy and are keen on reclaiming wasteland on the hillside at 50 to 60 degree angles and trying to plant buckwheat and maize, it will be impossible to change the present situation and we will become poorer and poorer.

TEXT OF ENGLISH ABSTRACT: The time of fusion of male and female nuclei and the duration of zygote stage after artificial pollination of different wheat varieties were studied. The purpose of this study is to find out a suitable time for irradiating the zygote in order to increase mutation rate and get more steady mutants.

Three wheat varieties were used, namely, Nong Da 139, a winter wheat, YLN 7926, a spring wheat, and YLN 7617, a wheat variety of the intermediate type. The processes of pollination through fusion of male and female nuclei to the beginning of the zygote stage are similar. They usually take 6-7 hours. But the duration of the zygote stage is different. For Nong Da 139, YLN 7617 and YLN 7926 it

[Continuation of YUANZINENG NONGYE YINGYONG No 3, 17 Sep 82 pp 1-6]

appears from the 7th to the 13 hour, from the 6th to the 11th hour, and from the 7th to the 23rd hour after pollination, and lasts 7 hours, 6 hours and 17 hours respectively. It is suggested that the duration mentioned above could be the appropriate period for irradiation of wheat zygotes.

TITLE: "Cytological Effects of ^{60}Co Gamma Radiation on Root Tip of *Vicia faba* in Different Cell Cycles"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 3, 17 Sep 82 pp 7-12

TEXT OF ENGLISH ABSTRACT: The sprouting seeds of *Vicia faba* were treated by ^{60}Co gamma radiation with the same dose (1850R) and the same dose rate (90R/min) at intervals of 2 hours for a whole day. Taking 1 day as a cycle, we carried out a cycle observation on the aberrations of cells.

The experimental results show that gamma radiation had an obvious inhibition effect on the mitosis of root tip cells of *Vicia faba* and there was an apparent difference in radiation sensitivity at different mitotic stages between the cells. The frequency of different types of chromosomal aberration was positively correlated with the number of total aberrations. However, irradiation at different stages of

[Continuation of YUANZINENG NONGYE YINGYONG No 3, 17 Sep 82 pp 7-12]

the cell cycle led to different results. When radiation took effect at the early S stage, the maximum chromosome aberrations amounted to 48.1 percent of the total aberrations, while in chromosome aberrations the fragments reached as much as 50 percent. When radiation took effect at the later S stage, the nuclear aberrations amounted to 86.1 percent of the total aberrations, while in nuclear aberrations the micronuclei reached as much as 82.8 percent.

Therefore, in radiation breeding attention must be paid not only to good material, proper mutagenic agents and adequate dosage, but also to appropriate stage of mitotic cycle of the sprouting seeds to be irradiated.

TITLE: "Selection of Wheat Mutant Long Fu 5009 Resistant to Root Rot"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 3, 17 Sep 82 pp 13-16

TEXT OF ENGLISH ABSTRACT: The dry seeds of the wheat variety "663 Red" were irradiated by ^{60}Co γ-rays and argonion lasers. The mutant strain "Long Fu 5009" was selected from the seventh generation for resistance to root rot. It produced more grain than its parent and the control variety. In inoculation experiments in 1978 and 1979 it displayed stronger resistance to root rot. As for maturity, it was not an extremely early type. The changes in awn type and glume color were not due to single gene mutation. Genes controlling the awn type and the glume color were of incomplete linkage.

TITLE: "A Study of the Activity of Corn Root System and Its Distribution in Soil"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 3, 17 Sep 82 pp 17-22

TEXT OF ENGLISH ABSTRACT: ^{32}P was used as the trace for investigating the activity of different corn roots and their distribution in the soil. The experimental results indicated that the corn roots arising from higher nodes (especially the aerial roots) were the main organs which absorbed the inorganic nutrients from the soil in the middle and late growing period of maize. The active sphere of the root system moved gradually downward as the growing season pushed on. A cylinder of 20 cm in diameter and 40 cm in depth, with the plant as the center, was marked to be the active region of corn roots. For the purpose of producing better yields, more attention should be paid to the aerial (brace) roots arising from higher nodes and to the extension of the rich soil layer.

TITLE: "A Study of the Nutrition of Rice Seedlings Grown in Soilless Culture in Greenhouse"

SOURCE: Shijiazhuang YUANZINENG NONGYE YINGYONG [APPLICATION OF ATOMIC ENERGY IN AGRICULTURE] in Chinese No 3, 17 Sep 82 pp 26-32

TEXT OF ENGLISH ABSTRACT: The technology of soilless culture and the nutrition of seedlings of early rice grown in a greenhouse have been studied with ^{32}P and ^{15}N as tracers. The experimental results show that it is necessary to give light to the seedlings at the one-leaf-stage because it can promote the greening of the seedlings and enhance the quality of the seedlings. The seedlings of the soilless culture can strongly absorb external nutrients before the trifoliate stage. Hence stronger seedlings of early rice can be produced by supplying the seedling with mineral fertilizers, and good harvests can be obtained from the seedlings of the soilless culture.

TITLE: "Morphological Changes of the Surface of the Eggs of *Rana amurensis* During First Cleavage by Fluorescence Microscopy--Receptors of Wheat Germ Agglutinin and Soybean Agglutinin"

SOURCE: Shanghai SHIYAN SHENGWU [ACTA BIOLOGIAE EXPERIMENTALIS SINICA] in Chinese No 3, Sep 82 pp 375-381

TEXT OF ENGLISH ABSTRACT: Receptors of wheat germ agglutinin (WGA) and soybean agglutinin (SBA) are present on the denuded living egg surface of *Rana amurensis*. Before cleavage these receptors distribute evenly all over the animal pole. At the onset of cleavage, numerous bright fluorescent granules which correspond to the protrusions in the scanning electron microscope are seen on the cleavage stripe and many bright radiated rays, identified as folds, are visible on the side of the cleavage stripe. Soon after, the new membrane having much less FITC-lectin binding ability appears and divides the cleavage stripe into three bright lines. The middle one is the primitive contractile ring. During cleavage, the new membrane increases gradually. However, when the denuded eggs are immersed

[Continuation of SHIYAN SHENGWU No 3, Sep 82 pp 375-381]

in a high concentration of WGA (500 γ/ml) before cleavage, the new membrane appears only for a short time, then vanishes, leaving a black streak. These results are in line with those found in newt's eggs. In a high concentration of SBA (100 γ/ml), the new membrane is exposed continuously but on a much smaller schedule. The contractile ring initially works normally, then fails to work, and the new membrane bulges out. Finally the new membrane disappears as do those in WGA.

In a few FITC-SBA stained eggs, a large dark halo, its center often coinciding with the center of the furrow, appears quickly and persists for several minutes to more than an hour, so that it may overlap with the halos seen on the second cleavage stripes. The darker overlapping area gradually decreases and eventually disappears, while the halos on the second cleavage furrows move away. Sometimes a bright halo may be seen on the egg surface. As the halo contracts, it becomes brighter and brighter. Finally many radiated stripes and a nipple-like structure are found in the center of the halo. A few receptors, however, remain or lag behind during the contraction of the bright halo. This indicates that the receptor can become mobile or increase its moving rate under certain conditions. The increasing of fluorescence, however, does not always result from the movement of the receptor, but from the movement of the cell surface. By pushing the evenly distributed fluorescent egg surface, many brighter lines appear at the folded places. An increase in fluorescent intensity due to the fold of the egg surface is also present, as are the bright radiated rays and granules at the cleavage stripe.

TITLE: "Callus Induction and Plant Regeneration in Dehulled Rice Seeds of the Hybrid Rice in *Oryza sativa* Subsp. *Japonica*"

SOURCE: Shanghai SHIYAN SHENGWU [ACTA BIOLOGIAE EXPERIMENTALIS SINICA] in Chinese No 3, Sep 82 pp 387-391

TEXT OF ENGLISH ABSTRACT: By using the hybrid rice material in *Oryza sativa* subsp. *Japonica*, we have studied the relationships between the different seed statuses and the efficiency of the callus induction. It is found that the results are good and the method is easy by culturing the dehulled hybrid rice seeds directly. If the seeds have germinating capacity, the induction frequency can reach 100 percent. By histological observations it is demonstrated that the callus can grow out from the hypocotyl position.

[Continuation of SHIYAN SHENGWU No 3, Sep 82 pp 387-391]

In the dehulled hybrid rice seed culture, the optimum concentration of 2, 4-D for the callus induction is 3 mg/1.

There are close relationships between the age of the callus and the frequency of the green plantlet differentiation. In general, the optimum age is 15 days old.

ORG: Nanjing Technological College of Forest Products

TITLE: "New Strategy of Forestry Development in China"

SOURCE: Nanjing NANJING LINCHAN GONGYE XUEYUAN XUEBAO [JOURNAL OF NANJING TECHNOLOGICAL COLLEGE OF FOREST PRODUCTS] in Chinese No 3, Sep 82 pp 1-4

TEXT OF ENGLISH ABSTRACT: According to the speech "Situation in Forestry and Our Task" delivered on 28 Oct 1981, then the Minister of Forestry, this article probes into the major points of the new strategy of the forestry development in China. 1) Forestry work should be focused on afforestation, forest protection and greening the country. This is the essence of the new strategy. In the past, the forestry work was unduly centered on timber production, which resulted in severe ecological disasters. Under such circumstances, strategical shift is something imperative. 2) The foundation of forestry theory and ideological basis of the new strategy is to recognize, according to the laws of economy as well as the law of nature, the important role of the forest in an all-around way. Needless to say, the forest can provide timber and various kinds of forest products, but what is more important is the fact that it has multiple functions and offers multiple benefits. 3) In the past, due to the influence of the erroneous "left" ideology, the enthusiasm of the peasants was dampened, thus resulting in such damage as low survival rate of

[Continuation of NANJING LINCHAN GONGYE XUEYUAN XUEBAO No 3, Sep 82 pp 1-4]

seedlings in afforestation. Therefore, we must now apply the party's policy to emancipate the minds of the peasants and bring out their initiative. 4) Backwardness in forestry science and technology is the chief cause hindering the production of forestry. To solve this problem, great efforts must be made to raise the level of forestry science and technology, advocate scientific management and popularize forestry education. Only in this way can forestry development be speeded up.

ORG: Research Department of Rural Economics and Agricultural Systems Engineering, Shanxi Province

TITLE: "A Preliminary Study of the Characteristics of Agricultural Systems Engineering"

SOURCE: Nanjing NANJING LINCHAN GONGYE XUEYUAN XUEBAO [JOURNAL OF NANJING TECHNOLOGICAL COLLEGE OF FOREST PRODUCTS] in Chinese No 3, Sep 82 pp 39-45

TEXT OF ENGLISH ABSTRACT: 1. Agricultural systems engineering is the application of systems engineering to the management of macro-agriculture, a modern technique in the organization and administration of the movement of macro-agriculture economics and of the productive activities of micro-agriculture.
2. Agricultural systems engineering is a branch of systems science, whose main objects of study are the logic, information and program in the field of agriculture, belonging to the category of "soft" science.
3. Apart from the common basic theories for systems engineering, such as operations research and computer science, agricultural systems engineering has its own specific basic theory, i.e., farming science, which studies the laws of conducting macro-agricultural production.
4. The objective of agricultural systems engineering is to speed up macro-agricultural production so that more material wealth can be created and to improve the systems of nature in order to create a desirable, reasonable and highly efficient ecological system.

[Continuation of NANJING LINCHAN GONGYE XUEYUAN XUEBAO No 3, Sep 82 pp 39-45]

5. Viewed from the standpoint of systems science, macro-agricultural production system has characteristics with complex mechanisms, i.e., regionalism, periodicity, comprehensiveness, systematism, orderliness and being subject to chain reactions. In conducting agricultural production, one should bear in mind all these characteristics and the actual conditions of the specific locality and time, analyze the contradictions and coordinate relevant links and factors, going forward step by step in dynamic equilibrium.

TITLE: "Studies on the Relationship Between Soil Moisture and Tree Growth in a Pine Forest Ecosystem in Nanjing"

SOURCE: Nanjing NANJING LINCHAN GONGYE XUEYUAN XUEBAO [JOURNAL OF NANJING TECHNOLOGICAL COLLEGE OF FOREST PRODUCTS] in Chinese No 3, Sep 82 pp 97-108

TEXT OF ENGLISH ABSTRACT: The pine forest ecosystem we have studied is situated at the purple mountain not far from Dr Sun Yat-sen's mausoleum, Nanjing, Jiangsu Province. Masson's pine trees (Pinus Massoniana Lamb.) constitute more than 80 percent of the total composition of the pine stand, are 12-14 years old, with a canopy density of 0.7, stand density of 120 trees/mu (or 1800 trees/ha), stand height 5.5 m, and average breast-height diameter 11 cm. The undergrowth is mainly intolerant grasses, 60-100 cm high, with a coverage of 40-50 percent. The soil is yellow brown earth, heavy loam to clay.

A formula for the moisture equilibrium in forest soil has been suggested in this paper to study the variations of soil moisture and their effects on tree growth. The main conclusions we arrived at are as follows:

The annual variations of soil moisture in a pine stand can be divided into four

[Continuation of NANJING LINCHAN GONGYE XUEYUAN XUEBAO No 3, Sep 82 pp 97-108]

phases in Nanjing region. During the phase from April to June, when the water supply is most important for tree growth, soil moisture is fairly sufficient, although a little uncertain at times.

There is no significant variation of soil moisture beneath 20 cm of the ground. Soil moisture there is much more stable than that at the layer above. So if we adopt some measures to make the roots of the trees penetrate deeper into the soil layers, they will absorb more water and grow better.

The height growth of trees and the growth of early wood and late wood are closely related to the hydrothermal coefficient of climate and the available water. In the April-June phase, the multiple correlation coefficient of the average height growth of trees to the hydrothermal coefficient of climate and the capacity of available is 0.962, and that of early wood growth of trees to those is 0.947. In the July to September phase, such a multiple correlation coefficient of late wood growth to those is 0.851. With the analyses of the correlations, it is possible to use the hydrothermal coefficient, especially together with the available water supply in soil, to predict the growth of the stand.

The pine stand can make the soil desiccative during the growing season and moist during the dormant season in the mountainous region in Nanjing.

TITLE: "Basic Method of Resolving the Problem of Aridity in Shanxi Province"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 10, 20 Oct 82 pp 2-5

ABSTRACT: In Apr and May, the author spent more than one month to visit the 20+ counties in Xishan, Pingchuan, and South Shanxi to talk with the local cadres and masses about the situation of agricultural production. The response he got was that the policy is good, the people are diligent, but all depend upon whether the weather is going to be helpful. Following a detailed observation and analysis of the problem, the author believes that it essentially involves the following: (1) The State cannot afford to invest a large amount of capital for water conservancy engineering at present; (2) The lack of water resources in the province; (3) Due to insufficient sources of water, some existing engineering structures have become ineffective; (4) The problem of aridity also involves water and soil erosion, sparse vegetative cover, uneven distribution of rainfall, and ecological imbalance. Following this analysis of the facts, the author presents in the paper a program of comprehensive treatment of the soil, the water, and the forests. The program is explained in some systematic detail, with concrete steps for its implementation. This paper originally appeared in SHANXI RIBAO 2 Aug 82.

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 10, 20 Oct 82 pp 11-14

ABSTRACT: In 1974 to 1980, 765 specimens were selected from 1,000 materials of farm varieties of soybean collected from 85 counties (cities) of Shanxi Province and grown for 2 years in the experimental field of the office. Based upon the classification of the author (1981) of soybean cultivars of the province into 6 ecological adaptation regions, the height of stalk, the number of branches, the number of nodes on the main stem, the height of pod formation, the ratio between grains and stem, the number of pods per stalk, the number of beans per stalk, the weight of stalk and beans, the average weight of 100 beans, the standard deviation, and the variation coefficient of the 765 specimens were analyzed. Based upon the analytical data thus obtained, the geographic distribution of the stalk characteristics and the geographic distribution of the yield characteristics are discussed separately in the paper.

TITLE: "Relationship Between Corn Head Smut and the Planting Time"

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 10, 20 Oct 82 pp 15-16

ABSTRACT: The major route of infection of the fungous disease of head smut of corn is soil. If the soil carries the disease, the temperature and humidity of the soil after seeding affect the severity of the disease. In areas of spring corn, the seeding time varies to create a variation of the soil temperature and moisture condition and hence the difference in the severity of the disease. Some scientists believe if seeding is early, the seedling stage is prolonged and there will be more opportunity for infection. Others believe the diseaseis milder if seeding is either early or late and the incidence of the disease is the highest if the corn is seeded at a proper time. In 1980-81, the authors carried out an experiment in the northern suburb of Taiyuan with corn of different disease resistance and different seeding times, followed by another experiment using different temperature treatments. Results indicate that seeding time has no effect on the disease-resistant varieties. With the susceptible varieties, proper early or late seeding may reduce the severity. With the highly susceptible varieties, the disease will be severe regardless of the seeding time; they should never be used.

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 10, 20 Oct 82 pp 17-19

ABSTRACT: In 1980-81, in the process of carrying out a survey of bovine breeds in Shanxi Province, the group discovered a new typeof oxen-- the Pinglu mountain oxen. Preliminary inspection indicates that it is primarily a draft animal, with some meat producing potential. The condition of its native habitat, its distribution and formation, its morphology and size, its work capacity, its feeding and reproductive characteristics, and its shortcomings and some suggestion for its improvement are discussed. This breed has a high content of good quality and tender lean meat. Related departments are urged to breed it and to open a market for it as a meat animal.

SOURCE: Taiyuan SHANXI NONGYE KEXUE [SHANXI AGRICULTURAL SCIENCES] in Chinese No 10, 20 Oct 82 inside backcover

ABSTRACT: This paper is a brief biography of the wheat breeding specialist, ZHAO Hongzhang who successfully bred out in 1970 the highly adaptable, lodging resistant, Aifeng No 3, yielding more than 1000 jin/mu. He was born in 1917 in Qi County of Henan and was a graduate of the Department of Agronomy of the Northwest College of Agriculture in 1940. Disheartened by the low wheat yield of his native Guanzhong due to rust and midge, he was determined to breed disease and pest resistant varieties of wheat and produced the high yield, good quality, and rust resistant Bima No 1 in 1947, just before the liberation. He joined the Communist Party in Mar 56 and was elected to the National People's Congress twice. His major writings include: "Process of Selective Breeding of Bima No 1," "A Superior Breed of Wheat," "Several Problems in the Wheat Hybridization Work," "Shaanxi Wheat," etc. A photo of the scientist is included.

SOURCE: Tianjin XUMU SHOUYI XUEBAO [ACTA VETERINARIA ET ZOOTECHNICA SINICA] in Chinese No 3, Aug 82 pp 167-171

TEXT OF ENGLISH ABSTRACT: This paper presents the karyotype studies on domestic pigs in southern China. The diploid chromosomes are 2n=38 in both sexes. The X-chromosome is a metacentric chromosome and the Y is a smaller submetacentric one.

The chromosomes are measured and divided into four groups according to their relative length, arm ratio and centromere index of each chromosome. The Nos 1 to 5 of group A are submetacentric chromosomes (SM); Nos 6 and 7 of group B are subtelocentric chromosomes (ST); Nos 8 to 12 of group C are metacentric chromosomes (M) and Nos 13 to 18 of group D are telocentric chromosomes (T).

[Continuation of XUMU SHOUYI XUEBAO No 3, Aug 82 pp 167-171]

Both the G-band and C-band are described, with the G-banding pattern revealing no significant differences with that of domestic pigs so far reported. The polymorphism of the C-band may be related to the varietal differences between domestic pig breeds.

TITLE: "Serological Identification of Porcine Respiratory Tract Micoplasmas in China"

SOURCE Tianjin XUMU SHOUYI XUEBAO [ACTA VETERINARIA ET ZOOTECHNICA SINICA] in Chinese No 3, Aug 82 pp 181-188

TEXT OF ENGLISH ABSTRACT: Twenty-one strains of micoplasma isolated from respiratory tracts of swine from six provinces, municipalities and autonomous regions of China were identified serologically and proved to belong to two species by the method of dry paper disc growth-inhibition test, using antisera to the Jinan strain isolated from pigs with "swine asthma" and to a mycoplasma hyorhinis-like strain L6. Twelve strains of the "swine asthma" pathogen out of the 21 isolated strains were of the same species.

The Jinan strain was proven to be identical with the type culture NCTC No 10110 of M. hyopneumoniae, and the strain L6 with the BTS7 of M. hyorhinis. The original causative agent of "swine asthma," widespread in China, was thus demonstrated to be M. hyopneumoniae.

TITLE: "A Study of the Pathogenesis of Experimental Escherichia Coli Enterotoxaemia of Swine"

SOURCE: Tianjin XUMU XHOUYI XUEBAO [ACTA VETERINARIA ET ZOOTECHNICA SINICA] in Chinese No 3, Aug 82 pp 189-193

TEXT OF ENGLISH ABSTRACT: Freeze-thawed lysates of hemolytic Escherichia coli 0139 were centrifuged. The supernatant was separated into three portions by Dextran gel (sephadex G-200) chromatography. The first portion was parenterally administered to seven weaned pigs. The clinical signs and pathology of the inoculated pigs were similar to those found in other endotoxin shocks. The second portion was parenterally administered to eight weaned pigs. Their clinical signs and pathological pictures were the same as those of the naturally occurring oedema disease of pigs. Experimental E. coli enterotoxaemia of swine can be divided into two categories: one is the "endotoxin shock type" produced by the endotoxin and the other is the "oedema type" caused by oedema disease principle.

TITLE: "Determination of Serum Transferrin Phenotypes in Swine"

SOURCE: Tianjin XUMU SHOUYI XUEBAO [ACTA VETERINARIA ET ZOOTECHNICA SINICA] in Chinese No 3, Aug 82 pp 194-197

TEXT OF ENGLISH ABSTRACT: Transferrin phenotypes have been detected in all domestic animals examined so far. Various investigations abroad have indicated some relationship between transferrin phenotype and reproductive performance in pigs, cattle and sheep. In order to explore such a relationship in Chinese pigs and to apply it to the selection and breeding of swine, the phenotypes of serum transferrin were examined in 217 samples from Ganzhou White pigs of Jiangxi Province by the starch gel electrophoresis technique. Protein in 180 samples occurred in various molecular forms exhibiting multiple band patterns on the stained gel after electrophoresis. According to Michael's work in which transferrin phenotypes were identified in starch gel electrophoresis by autoradiography with Fe^{59}, the locations of the bands were determined by electrophoresis relative

[Continuation of XUMU SHOUYI XUEBAO No 3, Aug 82 pp 194-197]

mobility. Six transferrin phenotypes (AA, BB, CC, AB, AC and BC) were separated in the Ganzhou White. The gene frequency of T_fBB was the highest among the breeds (including Yorkshire and Taiwan native swine) examined, while that of T_fAA was higher than that of T_fCC. The results obtained were in agreement with a genetic theory of serum protein.

TITLE: "Studies on the Secretion of Aflatoxin M_1 in Cow's Milk After Aflatoxin B_1 Feeding"

SOURCE: Tianjin XUMU SHOUYI XUEBAO [ACTA VETERINARIA ET ZOOTECHNICA SINICA] in Chinese No 3, Aug 82 pp 199-204

TEXT OF ENGLISH ABSTRACT: This observation was carried out with 12 dairy cows (crossbred) which were divided into 2 groups and fed separately with a diet containing 20 and 50 ppb of Aflatoxin B_1. The secretion of Aflatoxin M_1 in milk was found to be 0.52 and 1.58 ppb (on the average) respectively. The amount of Aflatoxin M_1 secreted was significantly related to the Aflatoxin B_1 administered. The rate of conversion of Aflatoxin B_1 was calculated to be 5.75 percent and 7.01 percent respectively, and the difference was considered to be significant. After stopping administration of the diet with Aflatoxin B_1 for 5 days, no Aflatoxin M_1 was detected in milk.

[Continuation of XUMU SHOUYI XUEBAO No 3, Aug 82 pp 199-204]

It is thus suggested that the content of Aflatoxin B_1 in mixed diet should be less than 20 ppb while the content of Aflatoxin M_1 in milk should be less than 0.5 ppb.

I. GENERAL INFORMATION

FIRST INSTITUTE OF AGROBIOLOGICAL GENETICS, PHYSIOLOGY INTRODUCED

Nanjing XINHUA RIBAO in Chinese 22 Sep 82 p 2

[Article: "Institute of Agrobiological Genetics and Physiology--A Brief Introduction"]

[Text] The Institute of Agrobiological Genetics and Physiology of Jiangsu Province was one of the first nine key agricultural research projects of our country. The completion of this project has provided significant conditions for our scientific agricultural research front to strengthen the basic research of applied technology in agrobiological genetics and physiology.

The tasks of Institute of Agrobiological Genetics and Physiology are: To place the main agricultural products as objects of research, apply the principles and methods of genetics and physiology to basic research, exploit new avenues, new techniques to improve varieties and plant breeding, and provide new breeding materials.

In accordance with the developmental needs of agricultural production and scientific research, the Institute has put emphasis, for the near future, on the following researches:

1. Research on genetics. The main objects of research are grain, cotton, and oil-bearing crops. New techniques of breeding, including chromosome process and distant hybridization, will be exploited. New variation materials and new methods will be created for breeding, and relevant genetic patterns will be investigated. In addition, it will create actively conditions in preparation for research on molecular genetics.

2. Research on growth genetics. The research will be mainly on how to use free cells and separated tissues to prodice a wide spectrum of varieties, introduce orthoselection and evaluation techniques, provide new materials necessary for breeding. The research will include variation, evaluation and selection, genetics of rice resistance, as well as techniques of manufacturing of test tubes for breeding horticultural, precious and rare plants.

3. Research on growth physiology. The reserach will be mainly on techniques of regulating and controlling growth. Relevant mechanism will be progressively explored at the level of cytology and molecular biology. In addition, in close coordination with research on high-yield plant breeding techniques, the research will provide relevant physiological bases.

4. Research on photosynthetical physiology. The emphasis is on increasing the crops' utilization capability of light energy, including orthoselecting techniques of non-directional mutation, the evaluation and utilization of mutants of high net photosynthetic ratio, their combined descendants, the technical system of selecting ans screening, by separating the colony, specific photosynthetic ecotypes, and supplying breeding parents. In addition, research will be done on utilization ratio of light energy by crops of different colonies, different levels and different structures, which will provide basis for high-yield crop breeding techniques.

5. Research on physiology of crops' adversity-resistance. The research will be mainly on the physiological effects of adverse circumstances on crops, to provide techniques to fight against diversity and secure stable yields. Research also includes the physiology of crops' adaptation to adverse circumstances, evaluation techniques of adversity-resistance of germ plasm sources.

6. Research on biochemistry. Mostly on demonstration of genetic features of crops and biochemical bases of their disease- and insect-resistance, as well as on relevant biochemical index necessary in breeding.

7. Research on analysis of variety quality, aminly to help the research on cultivation of new, high-yield, fine-quality and healthy varieties (such as selective breeding of new rape varieties with low erucic acid and low sulphoglucoside, or the breeding of new rice and wheat varieties containing high protein, etc.) A research will be progressively launched to formulate indexes for standardization of qualities of products, such as rice, flour, etc.

The successful execution of these research projects set down by the institute will lead to the refinement of varieties and improve breeding techniques. For example, with the success of research on method of cell culturing, the effectiveness of crop cultivation will be greatly increased. In the past, conventional breeding method was used to select plants in croplands after creation of variation. In case of rice, in one mu of field only 20,000 seedlings could be planted. And it could be done only once a year. By using method of cell culturing, one test tube can contain, at one time, 100,000 cells (that is, 100,000 single seedlings), which are equilvalent to the number of seedlings in 5 mu of field. And, we can use, each time, a hundred or a thousand tubes. The work can be carried out in laboratories continuously and all year round. Thus, breeding time will be greatly shortened and the speed greatly intensified. In the past, crop cultivation of adversity-resistance was carried on in the fields. Tremendous manpower was required to inoculate; some of the plants had to be taken to the producing areas to be evaluated and selected. If test tubes are used, inoculation can be carried out on culture media, and selection can be done by adding certain elements in the culture media. Cells with resistance will subsist and become seedlings, while cells without resistance will die and be eliminated. This process not only saves labor and expenses, but also is effective and achieves quick results.

ARTICLE VIEWS CONDITIONS FOR HYBRID RICE UTILIZATION

Beijing RENMIN RIBAO in Chinese 4 Nov 82 p 2

[Text] Since the appearance of hybrid rice produced by China's agricultural scientists, its reputation has spread all over the world. It is a giant contribution to China's grain production. In these last 2 years, however, it has been said that "the yield increase vigor of hybrid rice is deteriorating. The peak has passed. There is no more extensive action."

What is the prospect of development of hybrid rice? Is there still a yield increase potential? The reporter visited more than 10 provincial and municipal breeding specialists and those in charge of seed companies. Their answers are optimistic. Based upon a large quantity of convincing information they predicted that in the eighties the yield increase vigor of hybrid rice will contribute even more to the development of grain production.

Due to the fact that hybrid rice has an obvious heterosis, since 1976, its acreage has been rapidly expanding. From 1976 to 1981, the cumulative acreage of hybrid rice in the country reached 330 million mu and the grain production increased 30 billion jin. This is not something other superior breeds of rice can do. The yield increase vigor of hybrid rice is very obvious but this is not saying that there is no problem in this aspect of work. The phenomenon of mixing and the degeneration of hybrid rice seeds is one of the problems. It has been determined that for a 1 percent mixture of seeds, there is a yield reduction of 8-10 percent per mu. If the mix is 15-20 percent, the yield increase merit of hybrid rice is basically canceled out. The merit of hybrid rice and the demerit of mixing and degeneration are two mutually opposing aspects. Under a certain condition, the merit may be turned into a demerit but this type of transformation may be prevented by the work of people. This is not simply a theoretical inference; it is a fact proven by the practice in many areas. The Guangxi College of Agriculture and the Scientific Research Center of Huxi Farm, Jiangsu Province, etc., adopted a series of scientific measures to cause the purity of their hybrid rice seeds to be above 99 percent. Biological mixing of hybrid rice seeds can be controlled with a complete system and a heightened sense of responsibility during the processes of harvesting, sunning, threshing, packaging, and transporting the seeds. Using special tools may also prevent the seeds from mechanical mixing. A large quantity of research studies of scientists have proved that degeneration is an expression of mixing. It is a degeneration of various types of mutant stalks and is not a degeneration of the characteristics of the variety. It is not at all a phenomenon of "reverting to ancestral origin." That is to say if mixing can be avoided, degeneration can be avoided. The yield increase merit of hybrid rice is stable and reliable. In some areas the cost of preparing seeds is high and the yield is low. This is another factor affecting the extension of hybrid rice. It takes more labor and fertilizer to perpare seeds of hybrid rice than ordinary rice so that the households who prepare the seeds cannot obtain a real profit therefore they are not eager in this work. Insufficient supply of seeds will limit the extension of hybrid rice, however. In some areas, the quality of seeds is poor and the yield is low mainly because the work of seed preparation is scattered. When the work is scattered, there is no guarantee of isolation, the form of production is backward, and the management is imperfect. In order to overcome these defects, some areas where hybrid rice is being cultivated establish a system of a seed-preparing county with provincial lands or a system of a seed-preparing commune with provincial lands. For example, in Xuzhou Prefecture of Jiangsu Province, a large and continuous piece of land is used to prepare seeds and the unit yield is 32-56 percent higher than that of scattered seed preparation. In 1981, the national seed preparation averaged nearly 100 jin/mu, to reduce the rate of seed preparation versus grain cultivation from 1 : 12 or 1 : 15 to 1 : 10. This result greatly enhances the reputation of hybrid rice. These seeds have become the good seeds in which the farmers have faith. Some farmers walked 100 li to buy hybrid rice seeds. When a seed company sells hybrid rice seeds, it is always jammed with people.

The third problem in the extension of hybrid rice is the positive feeling of the farmers in using hybrid seeds. The concerns of the farmers in this respect are mainly the following: (1) They have been ripped off by misguidance before and are afraid of hybrid rice being unreliable; (2) Cultivating hybrid rice requires a high level technology and they are afraid that they will not be able to do it themselves. These types of worries cannot be removed by forcible commands. It would not do either simply to rely upon word of mouth. The only way is to help them resolve technical difficulties through demonstrations to induce the farmers to cultivate the hybrid rice. There are 2 production teams in Xiangtan, Hunan Province that did not use hybrid rice regardless of repeated requests by their superiors. The county seed company finally signed contracts with them for experimental cultivation. The production teams provided the land and the labor and the seed company provided seeds and technical guidance. The seed company would take 15 percent of all surplus yield and if there was a yield reduction, the company would pay all of it. In that year's experimental cultivation the yield was 800 jin/mu, 200 jin higher than that of ordinary rice. The farmers were thus convinced. In the following year, there was no need of mobilization, the farmers voluntarily cultivated hybrid rice in an acreage amounting to 90 percent of the total paddies.

Of course, after the farmers become positive about it, the attitude of scientific caution remains necessary in extending hybrid rice over large areas. It is necessary to go through experimentation to extend it step-by-step and absolutely not to be in a hurry to extend it all at once. The successful creation of hybrid rice is an important revolution in rice culture. In seed preparation, cultivation and management, everything is a new process.

Many links are involved which must be tightly put together. Some areas have a shortfall of technical capability. If the traditional cultivation method is used to crop hybrid rice, the effort will be spent without gaining a yield increase. For this reason, these areas should train a technical staff core to establish a specialized technical team quickly, and to popularize the knowledge of scientific farming. This is an urgent task, at present, in extending hybrid rice.

Presently, there are not yet many groups of hybrid rice in China. This is also an important reason for hybrid rice not being further extended over large areas. The few available groupings cannot adapt to China's vast territory. Between the south and the north, the temperature, the water, the soil, and the daylight conditions are very different. It requires a spirit of national cooperation to break through these barriers within a short period of time to produce a large number of new groupings with high heterosis, heat and cold tolerance and resistance, disease and pest resistance, and early maturity characteristics.

China is in a leadership position of the world in cultivating hybrid rice. If leadership is strengthened and some concrete problems are understood, acknowledged, emphasized, and resolved, suitable measures may be adopted to allow this bright star of the green kingdom to give forth even greater brilliance.

SHORT COMMENTARY ON DEVELOPING RECLAMATION AREAS

Beijing RENMIN RIBAO in Chinese 31 Oct 82 p 2

[Text] It is the agricultural policy developed in the party's 12 proposals that more grains and economic crops should be produced from the limited acreage of cropland and with the total development of forestry, animal husbandry, and fishery, the needs for industrial development and livelihood of the people are to be satisfied. How are state-operated farms going to implement this policy to create a new phase of economic development of agriculture and reclamation? The practice of intensive operation in Dawa Reclamation District of Liaoning Province to raise the economic benefit is an important answer to the question.

Dawa Reclamation District changed its extensive operation to intensive operation to increase its yield of grain per mu and its commercial grain supply 2.1-fold and 4.5-fold respectively over those of 1980, the year of the best harvests for all the farms of the country. The profit per mu was many times higher. The natural conditions of the majority of farms in the country are better than those of Dawa Reclamation District. If all are to practice intensive operation to produce 100 jin/mu more grain, the supply of commercial grain each year may more than double. What a great potential this is!

For the state-operated farms to practice intensive operation, each must start from its own conditions and walk its own road. Presently, many farms have excess manpower, which is growing and at a relatively fast speed. Some farms are burdened by a manpower surplus, on the one hand, and practicing extensive operation, on the other. They are not willing to invest more manpower in fieldwork. The result is vast seeding and little harvest. This situation definitely cannot continue. Practice has proved that with respect to an intensive operation, the farms should start from an increase of labor investment. The production accumulation will increase from the increased harvest. In this manner, less money is needed to reap more benefits. The other important real condition of the farms is their high science and technology capabilities. The nucleus of intensive farming is technological intensiveness. Thus, for the farms to practice intensive operation is to utilize their own science and technology capacities fully to adopt advanced and useful agricultural science and technology wherever it is best suited.

The central purpose of practicing an intensive operation is to raise the economic benefits. It invests more manpower, materials, and adopts more scientific techniques to use the existing cropland, in order to obtain higher yields and higher value products. In order to do this, it is necessary to handle the relationship between input and output scientifically and to proceed with concrete analysis of input and output of every item of the production economy so that a scheme of optimal economic benefit may be selected to reach the goal of a large-scale increase of the economic benefits.

To strive to raise the unit yield by intensive farming to increase the productivity of the land is the best way of increasing the yield and increasing the income for state-operated farms. They should not eye grain production only. They should put more emphasis on comprehensive operation and comprehensive utilization. On the one hand, the limited land should be fully utilized to obtain a high yield of grains and, on the other hand, multiple operations should be developed in a big way to process farm and animal products and to practice comprehensive operations in farming, industry, and commerce so that the value of the products produced from unit area of land may double and multiply to cause the productivity of the land to be several times to several tens of times higher.

REQUIREMENTS FOR STRENGTHENING FINANCE IN COMMUNE, BRIGADE ENTERPRISES

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] in Chinese No 10, 6 Oct 82 pp 10-15

[Article: "Ministry of Agriculture, Animal Husbandry and Fishery; Ministry of Finance; Agricultural Bank of China; Requirements in Reorganizing and Strengthening Finance Work in Commune and Brigade Enterprises"]

[Text] All provincial, municipal, and autonomous region bureau of commune and brigade enterprises, departments (bureaus) of finance, and agricultural banks:

Based on the spirit of documents No 1 (1982) issued by the CPC Central Committee and No 10 (1982) issued by the State Council, and in order to assist and promote commune and brigade enterprises to further and properly carry out their financial reorganization, strengthen the management of financial affairs, and correctly handle and rectify financial affair problems which arise as a result, the following requirements are presented for the reorganization and strengthening of financial affairs work in commune and brigade enterprises:

I. Must strengthen leadership of commune and brigade enterprises and conscientiously carry out reorganization of financial affairs

In the last few years, the development of commune and brigade enterprises has been very rapid and it has contributed to the development of the national economy, in supporting agricultural production, and in increasing the income of the members. However, because of the poor capability of the cadres, relatively weak foundation work, and inadequacies in the systems of financial affairs management and bookkeeping and accounting, many problems still exist. To correct these problems, at the same time that we promote necessary enterprise readjustment in accordance with the party's principles and policies, requirements of the national economic development, and production, supply, and marketing conditions, we must also conscientiously implement and develop the reorganization work of financial affairs and correct the conditions of management confusion and disorderly accounting.

The major tasks in the reorganization of the financial affairs of the commune and brigade enterprises are to find out the real situation, overcome confusion, perfect the systems, improve management, plug loopholes, increase income and reduce expenditures, straighten out financial and economic disciplines, correct unhealthy trends, and deal a blow to serious criminal economic activities. The basic objective is to improve the economic benefit and promote the healthy development of the commune and brigade enterprises. The purpose of the reorganization of the financial affairs is to improve management and administration and to promote production. It should not adversely affect production. In the overall process, the work of enterprise readjustment and reorganization, the work of strengthening financial affairs and accounting, and efforts to deal a blow to criminal economic activities must be closely united and arranged on an overall basis.

The work of reorganizing the financial affairs of the commune and brigade enterprises is large, involves a wide area, and is heavily political. It must be carried out through unified deployment, step-by-step in stages and with planning, under the unified direction of various levels of the party committee and the people's government, coordinated by related departments, and based on the spirit of related documents of the central government and the State Council.

The financial affairs reorganization is a total tackling of the finance and accounting work of the enterprises. It is also a project for a major improvement of management and administration. Thus, it must be carried out through the method of experience summarization and work improvement. A mass movement is not carried out, but it must follow the mass line in investigation and studies to determine the problems clearly and to solve them properly. Before the financial affairs reorganization of an enterprise is completed, checking and acceptance must be organized. Areas not meeting requirements must be corrected and whatever is lacking must be added. This cannot be merely going through the motions.

II. Conduct overall property accounting

In the work of reorganizing the financial affairs of the commune and brigade enterprises, a clear account on an overall basis must be made of the properties of the enterprise. This includes the entire fixed assets of the enterprise, materials, products, expenses to be allocated, cash, deposits, and various accounts receivable and payable. In the accounting of properties and materials, we must check both goods and accounts, determine clearly quantities actually on hand and shortages, and clearly identify the portion for normal production needs, the amount of excess and overstock, and the amount that is damaged or otherwise not usable because of property changes. The expenses to be allocated should be differentiated between those which are rational and those which are not. The accounts receivable and payable should be clearly identified by customer. They should be clearly separated as accounts for normal settlement, accounts for arbitration, overdue accounts, and accounts requiring further treatment. A detailed list should be made according to units or individuals. Cash shortages, errors, and white slips [of I.O.U.'s in the warehouse must be clearly determined.

Results of investigation should be reviewed and approved by the commune or brigade. Those that should be verified by related upper level departments should be transmitted immediately for verification and approval. Based on the actual figures after review and approval, the enterprise should make the necessary adjustments on the books. After the investigation, the accounts must tally with the facts. Problems identified from the investigation should be handled according to the document No 10 (1982) issued by the State Council, and the finance and accounting system for commune-operated enterprises and its supplemental regulations established by the Ministry of Agriculture and Ministry of Finance. Problems of a special nature should be referred to the enterprise management department and finance department in the province, municipality, or autonomous region for resolution according to the spirit of related documents of the central government and the State Council. The designed method of handling should be transmitted to the provincial, municipal, or autonomous region people's government for approval before implementation.

The reorganization work must also be based on the concrete conditions of the individual enterprise and its prominent points. In general, emphasis should be placed on solving such problems as serious overstocking of materials and products, excessively huge credits and liabilities, and confusion in cash management. Measures should be adopted to employ unused materials and active steps should be taken to manage surplus and unneeded materials. For overstocked products, on the one hand, outlets should be expanded, avenues increased, and sales actively pursued. On the other hand, production plans should be rationally adjusted, output should be controlled, and quality should be improved to avoid additional overstocks. For credits from banks and trusts which are due or overdue and various moneys that should be paid, a payment plan should be prepared and an active effort should be made for their payment or return. Money that should be paid should be quickly received. A time limit should be set for money owed by individuals, and leaders and cadres at various levels should take the lead to return money owed. For units or individuals who owe relatively large sums of money and who are not making a conscientious effort to pay back, the enterprise has the authority to collect compensation fees based on the interest rate of bank loans. Formal reviews and transfer of account procedures should be carried out to take care of the "white slips" in place of cash in the warehouse. At the same time, efforts should be made to get the moneys back. In the future, no one will be allowed to approve these slips and draw cash without going through the specified procedures. The use of "white slips" in place of cash for payment will not be permitted.

III. Control capital construction and strictly enforce review and approval procedures

The capital construction of commune and brigade enterprises includes procurement for expansion, reconstruction, excavation, innovation, and transformation in order to have fixed assets. The management of all these projects should be strengthened. They should be strictly controlled according to the spirit of the State Council document No 77 (1981) and reviewed and approved according to established procedures.

To develop the production of commune and brigade enterprises, we should first see if it can be done through the development of potential, innovation, and reconstruction of the existing enterprise. Capital construction should not be planned whenever problems can be solved by developing the potentials of existing facilities. If capital construction must be planned and implemented, there should be a significant amount of self-developed funds, the principal of acting according to one's capability must be insisted upon, and every effort should be made to achieve savings in investment and rapid results. Generally, new projects should not be started where a shortage of investment funds still exist for a similar project started in the past, where the sources of investment fund are not firmly arranged, and where circulating funds are not adequate. To carry out capital construction through the indiscriminate charging of costs, diversion of circulating funds, or indiscriminate transfer and borrowing of resources is not permitted.

All provincial, municipal, and autonomous region management departments and finance departments should develop methods to control capital construction by the commune and brigade enterprises based on the principle of different levels of control for different businesses and different size operations. The developed methods are to be reported to the provincial, municipal, or autonomous region people's government for approval before implementation. The practice of taking action first and reporting later or going one's own way is strictly forbidden. For capital construction started without the required reporting and approval, finance will not arrange supporting funds and banks and trusts will not provide any credits or start an account for the purpose of final accounting. Furthermore, the responsibility for the action should be pursued and dealt with.

Existing capital construction projects should be put in order. They should be reevaluated. Projects which do not meet the policy of adjustment and those which are in the "fishing" category should be stopped, changed, or slowed down. For projects which have been completed and have started production but had not gone through examination and acceptance, should go through the process. For projects which have exceeded their planned construction time, the reason for the delay should be determined and remedial measures should be presented.

IV. Properly handle financial work for closed, suspended, merged, and transferred enterprises

During the period of readjustment and reorganization, some of the commune and brigade enterprises were closed, suspended, merged, or transferred. Based on their individual and varying conditions, the clearing of properties and transfer work for these enterprises must be properly carried out to avoid losses and wastes.

The properties and materials of closed and suspended enterprises must be thoroughly checked out and a detailed inventory must be compiled. Special persons must be assigned for their safekeeping and handling. These properties and materials must not be transferred privately or used for other purposes. Their seizure for private use by any units or individuals is strictly forbidden. In case of violation, economic responsibilities and legal responsibilities should be pursued.

The credits and liabilities of closed and suspended enterprises, including loans to be paid back and taxes and finance circulating funds, should be cleared up within a s et time limit. They should be actively collected or repaid. If the cleared up receipts of a closed or suspended enterprises are insufficient to cover its liabilities, the repayment to cover the deficit is the responsibility of the commune and brigade that the enterprise is subordinate to.

For those merged or transferred enterprises which are released to brigades or production teams according to the principle of mutual economic benefit, the transfer of financial affairs and loans must be properly processed. For those which are merged or jointly operated with other enterprises, a contract must be signed and the work of computation of shares and bookkeeping must be properly carried out. For enterprises which need to change their production, the original facilities and materials must be fully utilized and the funds needed for the shift of production are to be actively raised and arranged on the foundation of developing the internal potentials of the enterprise.

The land occupied by closed down and suspended enterprises should be cleaned up and returned to the production teams as soon as possible. Before the processing of closed down, suspended, merged, and transferred enterprises is finalized, the original enterprise responsible person and the finance and accounting responsible person have the economic responsibility for the security of all the properties and materials of the enterprise and for clearing up its credits and liabilities. At the time this clearing up process is finalized, they must prepare a special report which, along with related documents, file materials, account reports, etc. are to be turned over to the commune or brigade in good order for review and acceptance. Only then are their responsibilities completed.

V. Adjust profit distribution relationship and strengthen profit utilization control.

In the distribution of profits of commune and brigade enterprises, the major problem at present is the adjustment of the relationship between the commune and brigade and the production team and commune members and the increase of actual economic benefits for the production team and commune members.
Another important problem is the adjustment of the relationship between the commune and brigade and the enterprise and the expansion of the self-determination authorities of the enterprise. The ratio of profit distribution of commune and brigade and the enterprise and the expansion of the self-determination authorities of the enterprise. The ratio of profit distribution of commune and brigade enterprises should be rationally adjusted based on the existing foundation, the principle of giving consideration to the interests of the state, the collective body, and the individual, and the spirit of controlling investment for capital construction, enriching the circulating fund of the enterprise, supporting agricultural production, and gradually raising direct distribution to the commune members. In order to guarantee and expand the self-determination authority of the enterprise, the practice of percentage retention of profits by the enterprise must be implemented and this percentage figure must be increased appropriately. Because of the drastic differences in the level of development of commune and brigade enterprises and the level of income of the commune members, the adjustment of the profit distribution ratio should be determined individually according to local conditions and should not be treated all in the same manner.

For the purpose of strengthening the control of profit utilization, the procedure for transmitting profits upwards and the limitations of profit utilization must be based strictly on those established by the higher level. Without approval, they cannot be changed or expanded by the commune and brigade enterprises.

Commune and brigade enterprises must transmit profits to the communes and brigades according to specified time frame and ratio (or fixed amount). The communes and brigades must not secure profits from the enterprises outside the specified time frame or beyond the specified ratio (or fixed amount). No unit or individual may use any reason to transfer for other uses the profits, funds, and products of an enterprise.

VI. Strictly enforce financial and economic discipline and correct unhealthy trends

The strengthening of financial and economic discipline and the correction of unhealthy trends are essential measures in the adjustment and reorganization of commune and brigade enterprises. They are also important aspects in the reorganization of financial affairs. The propaganda and education on obeying disciplines and laws and on system implemention must be conducted for the cadres and enterprise personnel. All activities of violating financial and economic disciplines must be forcefully stopped.

The commune and brigade enterprises must pay taxes according to tax laws and regulations. Stealing taxes, evading taxes, and delaying and owing taxes are not permitted. Operating funds must be raised and arranged according to regulations specified under the financial system. They cannot be diverted indiscriminately from within the enterprises or from related units. Responsibilities must be carried out and economic relationships handled according to signed economic contracts. Extravagance and waste, entertaining guests, and giving gifts must be opposed. The drawing of "social expenses" and other variations of violating financial and economic activities are to be prevented. The wage and award systems established by the commune member representatives meeting or shareholders meeting in accordance with state regulations and approval must be carried out. The concoction of pretexts and indiscriminate distribution of awards outside specified conditions of the system is not permitted. The borrowing, trial use, or other forms of making use of funds and materials of collective organizations is not permitted.

Cadres and enterprise personnel violating financial and economic and disciplines should be dealt with seriously. Light offenses and first offenders are to be handled with criticism and education. Disciplinary actions should be taken against serious offenses and repeat offenders, in addition to recovering the funds and materials unlawfully taken. We must struggle against such unlawful acts as embezzling properties, graft and stealing, bribery, accepting bribes, profiteering, and smuggling or selling smuggled goods. Persons engaged in serious criminal activities should be punished by judicial organizations according to the law.

VII. Establish and perfect finance and accounting systems and strengthen finance and accounting personnel

During the checking and reorganization, the commune and brigade enterprises should conduct an investigation on the establishment of the finance and accounting systems and their implementation. Primarily, a clear check should be made on whether or not systems should be established, whether or not they meet the requirements of the state, and what problems still exist in the areas of strengthening management and administration and improving economic benefits. Commune and brigade enterprises should, on the basis of the results of the investigation, establish a plan so that the finance and accounting systems are strengthened and perfected as quickly as possible to develop their management and supervision effects.

Systems of working must be specified and normal financial affairs and accounting procedures must be established. The foundation work of original recordkeeping, measuring and calculating, receiving and issuing materials, and quota management is to be strengthened. The basic systems of capital construction reporting and approval, money management, review and approval of expenditures, distribution and utilization of profits, tabulated bookkeeping, and cost accounting are to be established and perfected, and their thorough implementation must be enforced.

The commune and brigade enterprises should fully develop the supervisory effect of financial affairs and accounting. Through the review and approval of accounting vouchers, examination of financial receipts and expenditures, and analysis of economic results, loopholes in financial affairs are guarded against, financial and economic disciplines are strictly maintained, and problems are immediately brought to the attention of the leaders and upper levels for review.

Extremely important attention, must be given to the problem of democratic handling of finances. A system of plan review and approval and final accounting, with commune member representatives and enterprise personnel representatives participating should be established, so that the masses can truly be the masters of their finances and participate in the management of financial affairs.

Currently the condition of "one inadequate, two weak, and three unstable" exists among the finance and accounting personnel of commune and brigade enterprises. Effective measures must be adopted to correct this condition as rapidly as possible. Up to now, the commune management departments and the commune and brigade enterprises with relatively large production potentials and requirements for stable development still do not have specialized finance and accounting personnel. These personnel must be made available rapidly based on the spirit of selecting the good and utilizing the able and adopting the methods of adjusting between surplus and shortage, short duration training, and the old bringing along the new.

Relative stability must be guaranteed for the finance and accounting personnel. For the various levels of finance and accounting personnel, their duties and responsibilities must be clearly determined, their authority must be protected, the direction of their ideology and work must be strengthened, and their economic remuneration must be properly solved.

Training for finance and accounting personnel must be strengthened. A systematic training may be carried out on the basis of the requirements of the finance and accounting systems established and published by the Ministry of Agriculture and the Ministry of Finance. It is also possible for the training to be based on developments in the work activities and conducted by business categories and by special subjects. Another method would be to carry out training through on-the-job support and direction by a combination of evaluation and comparison, mutual checking and review, and summarization of lessons from work experiences and, thus, the policy level and work ability of the finance and accounting personnel are continuously improved.

VIII. Develop the supervisory and regulating effects of finance and banking

Through the distribution of funds and management of credits, various levels of finance and banking (including credit associations, other areas are the same) should develop the effects of their supervision and regulation during the adjustment and reorganization of commune and brigade enterprises. Subject to availability of financial resources and funding, necessary support should be provided to enterprises which meet the policy requirements of adjustment and reorganization. Active support should be provided to minority regions, mountain regions, far border regions, and poor regions where the conditions for developing commune and brigade enterprises are available and where good economic benefits may be obtained. For those who engage in blind development, who supplement their circulating funds with profits earned against regulations, divert circulating funds for capital construction, as well as those who do not follow the stipulated procedures in adjustment and reorganization, the finance and banking units must adopt restrictive measures or even discontinue their financial support and refuse to grant loans.

The finance departments together with the management departments must properly manage and use their finance to support the commune and brigade enterprises in their investments and turn around funds. The turn around funds must be recalled on schedule as specified in the contracts in order to speed up the turn around. Attention must also be paid to summarizing experiences and further improving economic benefits.

In extending loans, the banks must conscientiously carry out the principles of the three investigations system (investigation prior to granting, evaluation at time of granting, and checking after granting). The bank must properly control the use of a loan and make sure that it is repaid on time. Efforts must be made to improve the economic benefits of the loan.

The finance and banking units must strengthen the supervision and periodically check the commune and brigade enterprises in their conducts related to finance and economic disciplines, pricing policies, payment of taxes, and the use and return of loans and turn around funds. They must continue to assist the enterprises in carrying out their financial affairs reorganization, establishing and perfecting their finance and accounting systems, training of finance and accounting personnel, and strengthening accounting work. They must properly conduct investigation and studies, reflect new conditions and new problems that may emerge during the adjustment and reorganization, present ideas for solution, and push forward the healthy development of the commune and brigade enterprises.

PROCUREMENT, SALES OF AGRICULTURAL, SIDELINE PRODUCTS DURING BRISK SEASON URGED

Shijiazhuang HEBEI RIBAO in Chinese 21 Oct 82 p 2

[Article by Hung Chen [7703 2525]: "Properly Carry Out the Procurement and Sales Work of Agricultural and Sideline Products During the Brisk Season"]

[Text] In his report to the CPC 12th National Congress, Comrade Hu Yaobang clearly pointed out: "The quality of commercial work directly affects industrial and agricultural production and people's daily living.... On the foundation of a complete understanding of the conditions and conscientious summarization of experiences, we must concretely improve commercial work and vigorously dredge, widen and increase the waterways of circulation so that goods will have their free circulation, materials will have their use, and commerce will fully develop its influences in pushing forward production, leading production, safeguarding supplies, and promote economic prosperity." Currently, to welcome the arrival of the market's brisk season, the proper development of the work of procurement and sales of agricultural and sideline products is to properly carry out commercial work in accordance with the directive spirit of Comrade Hu Yaobang in order to meet the needs of economic development.

(I)

Because of the firm implementation of the various policies for the rural areas, correction of the "left" ideology, implementation of various forms of production responsibility systems, and the fact that the production positiveness of the large numbers of peasants have been greatly aroused since the party's Third Plenary Session, and the relatively good weather conditions this year, an overall abundant harvest has been achieved in our province. Multiple enterprises have also had some very important developments. A rapid development has been achieved especially in the breeding industry with the appearance of many specialized households. We can say that the entire rural area is full of vitality and a great situation is just beginning to unfold.

The development of the agricultural and sideline industries has greatly enriched the brisk season market this year. First, the peasants have asked to sell greater quantities of agricultural and sideline products. Now they are concerned that they will not be able to sell the things they have produced. At the same time, because of the changes in the format of selling to the state, which is now largely on the household by household basis, the work of commercial procurement has greatly increased. Faced with this requirement, the staff and workers of the commercial departments must actively solve the possible emerging problems of "difficult to sell corn," "difficult to sell peanuts," "difficult to sell fruit," "difficult to sell pharmaceutical materials," "difficult to sell pigs," and "difficult to turn over cotton." At the same time, after the peasants have sold their products, they will want to buy needed peasants have sold their products, they will want to buy needed industrial products in return, such as production materials, construction materials, and daily consumer products. We must do everything possible to satisfy the needs of the peasants. We must investigate the basic market conditions and the quantities and specifications of the products that the peasants want to sell. How many industrial products will the peasants need, what kind and what quality? How much of these have been prepared for sale? We must have clear answers to these questions, so that the supply and sales work for this year's brisk season market will be properly carried out.

(II)

The peasants have produced for us large quantities of agricultural, sideline, and special native products. This is the result of their hard labor. The commercial departments should properly procure these products. If we do not do this work well and the peasants cannot sell what they have produced the products are left in their hands or even become spoiled, the productive enthusiasm of the peasants will be seriously damaged, which will be harmful to the continued development of the rural area. We should also understand that although the production of the peasants has increased it does not mean that our social needs are satisfied. It does not mean that our demands for agricultural, sideline, and special native products have increased. Actually, our demands are still not enough. Our commercial departments must make the maximum effort to procure all the products the peasants want to sell and in turn push the marketing of these products. The commercial departments must procure the products under the state's centralized procurement and assigned procurement plan. Vigorous efforts must be made to push the sale of the Class 2 products and the large quantities of Class 3 products through many different channels after the assigned procurement tasks have been completed (contracts between agriculture and commerce for key Class 3 products must be carried out). The state-operated commercial enterprises and supply and sales cooperatives must proceed with organizing work, direct the production of the peasants and the sales promotion work, direct the production of the peasants and the sales promotion work, direct the production of the peasants and the sales promotion work, and cannot allow the production results of the peasants to incur losses. One is to persist with the contracting for grains and oil without change and also to persist with making up the shortages from the abundant. The grain departments must open up, not limit, procurement. Wherever there is a discontinuation or limitation on procurement, the responsibility for such an action must be pursued. This must be announced to the masses so that they can supervise the implementation. At the time of procurement, the livelihood of the people must be properly arranged. After the state's procurement and excess procurement tasks are completed, negotiated procurement must be actively developed. Two is that in cotton procurement every effort must be made to procure all the cotton delivered to the cotton station on the same day. A schedule must be arranged to guarantee procurement.

Three is that there should be procurement methods for other agricultural, sideline, and special native products to guarantee their procurement and further sales. Fouris to increase procurement network locations and train working personnel. This means not only training in techniques but also training in ideology. Civilized and courteous trading is to be achieved.

(III)

The rural area is the principal part of the market. With the continued development of the rural product economy, the procurement and sales tasks of agricultural and sideline products must become greater each day. At the same time, with the increase of economic income by the peasants, their requirements for production and daily living materials will also continue to increase and the supply task for industrial products will also become greater. Thus, we must change from the past of laying particular stress on the urban market and neglecting the rural market to not only paying attention to the urban market but also giving greater attention to the rural market. When rural procurement and sales activities are properly developed, a new prospect will emerge in the entire commercial work. We must thoroughly fulfill the "Decision" of the State Council. The principal method of extending the wholesale network is by joint operation between the state and the cooperatives. Other methods must be based on local conditions. No matter what method we adopt, we must pay attention to rational distribution and think in terms of economic benefit. It must be based on the direction of flow of the goods. The establishment of network locations should not be based on administrative divisions. The reorganization of the rural shuangdaidian [7175 0108 1648] is a requirement based on the objective conditions and the trend of the time. However, the masses must be consulted on whether or not to make the change. The overall principle is to facilitate the movement of industrial products to the rural areas and to adopt many methods in further expanding the sales activities of industrial products in the rural area. The sales troops already organized must be stabilized and expanded. Exchange meetings and sales exhibits must be widely organized. Mobile sales to the rural areas must be vigorously organized in order that the masses may come face to face with the goods. For overstocked goods in the warehouses, such flexible methods as moving to another warehouse for commissioned sales, increasing discount rates, and delayed payment must be continued. Retail units should also be encouraged to actively promote the sales of these goods. For some stagnant goods, consideration may also be given for the buyer to enjoy the lower wholesale price after a certain quantity has been purchased in order to encourage greater sales.

In order to properly move industrial products down to the rural areas, various areas should organize mobile delivery at specified locations and specified times. Combining fixed location wholesale with mobile delivery is a good method and must be vigorously promoted.

The waterways for the circulation of goods must be further dredged open, widened, and increased. The first thing is to vigorously dredge open the main waterway of state-operated commercial enterprises so that we will truly achieve the goal that goods will have their free circulation and materials will have their use. At the same time, based on market demands, the development of collective commercial enterprises and individual enterprises must also be continued, especially in the small general merchandise trade and the repair and service trades. After the communes and brigades have completed their unified procurement, assigned procurement, and state procurement contracts, they may also sell the remaining products themselves. Some of these products which cannot be sold locally may also be sold to distant places.

(IV)

For a long time, we have been accustomed only to procurement, transfer, and supply according to plans. We have not paid attention to investigations and studies, we have not understood the market information very well, and we have not organized the sources of supply on a timely basis according to changes in market supply and demand. Thus, it is not possible to satisfy the production and daily living requirements of the masses to the maximum extent. This kind of supply system ideology and style must be changed. We must learn to do business and learn civilized trading. We must strengthen the market evaluation and forecast work and properly gather market information in order to provide information to the industry on a timely basis. Both industry and commerce must improve their sensitivity and ability to react to market changes. This is one of the basic conditions in organizing the production and circulation of commercial goods and the market supply. For this reason, the various levels of leadership must put in hard work and exert great efforts to properly carry out this work.

CANGZHOU MAKES FIVE BREAKTHROUGHS IN WHEAT PLANTING

Shijiazhuang HEBEI RIBAO in Chinese 21 Oct 82 p 1

[Article: "Plant to New Level; Create New Prospects; Wheat Planting in the Cangzhou Region Makes Five Breakthroughs This Autumn"]

[Text] The Cangzhou region treated wheat planting as the key practical action in fulfilling the spirit of the CPC 12th National Congress and in creating new agricultural breakthroughs. The rate of planting was faster than last year and quality was better than previous years. By 16 October the task of planting 5.7 million mu of wheat in the entire region had been basically completed.

There were five breakthroughs in the quality of wheat planting this autumn in the Cangzhou region. The first was the large area of moisture addition, with an increase of area of 6 percent over last year and basically achieving the condition of planting with adequate moisture. The second was more application of fertilizers, especially the combination application of nitrogen and phosphorous fertilizers which was more than any previous year. Based on an investigation of the five counties of Mengcun, Nanpi, Wuqiao, Jiaohe, and Dongguang alone, the areas with combination application of nitrogen and phosphorous fertilizers represented 66 percent of the total planting area. The third was better land preparation. Generally, the three ploughings and four rakings were carried out, achieving the condition of soft at the top and firm at the bottom which has not been accomplished in many years. The fourth was the planting of more wheat which was suitable for the season. A total of 1.86 million mu of Bailu wheat were planted in the region this autumn, an increase of 750,000 mu over last year. The acreage of Qiufen wheat was 2.96 million mu, an increase of 500,000 mu over last year. The fifth was scientific planting. This was particularly true with dry planting of alkali land wheat, which employed technical innovations in cultivation. In the 25,000 mu of dry planting of alkali land wheat in the Dongguang County, the new technique of "four changes and one early" cultivation was promoted.

New breakthroughs in the quality of wheat planting were achieved this autumn in the Cangzhou region because of the conscientious and thorough practice of the spirit of the CPC 12th National Congress by the various levels of party and government leadership organizations. More than 7,000 regional, county, and commune cadres in the region personally went to the basic levels to publicize the fulfillment of the spirit of the 12th National Congress and assist the commune members in wheat planting. For the more than 83,000 households in the region having difficulty planting wheat, the "five assists and one contract" was carried out. These were assists in funds, labor, livestock, well tools, and techniques. The cadres "contracted" for wheat planting for households having difficulties. Activities of mutual assistance were also implemented among the commune members and the communist style was greatly developed. At the same time, technical service work was vigorously developed. More than 400 technical cadres were released from regular work to travel to the rural areas. They took hold of over 43,000 model scientific and technical households, assisted the communes and brigades in establishing over 2,600 technical study classes, developed technical consulting service work in the fields, and pushed forward scientific wheat planting.

LARGE SALES OF CHEMICAL FERTILIZERS OUTSIDE PROVINCE QUESTIONED

Shijiazhuang HEBEI RIBAO in Chinese 21 Oct 82 p 2

[Article by staff: "Why Are Large Quantities of Our Province's Chemical Fertilizers Sold to the Outside? The Sale of Large Quantities of Hebei's Chemical Fertilizers To Outside the Province Has Increased the Contradiction Between Supply and Demand; Recommend That This Problem Be Solved Quickly"]

[Text] The sales of Hebei's chemical fertilizers have gradually increased in recent years. In 1965, these sales amounted to 271,000 tons but increased to 957,000 tons in 1970, an increase of 340 percent. In 1975, the sales totaled 1,344,000 tons, an increase of 40 percent over 1970. By 1980, the sales reached 2.93 million tons, an increase of 120 percent over 1975. In 1981, the sales totaled 2,633,000 tons, which represented a decrease of 11 percent over 1980.

Based on investigative analysis by related departments, the demand for chemical fertilizers in our province in the next few years will be: 4.19 million tons in 1982, 4.64 million tons in 1983, 4.83 million tons in 1984, and 5.04 million tons in 1985.

In addition to the state's unified distribution and allocation to outside the province, our current production capacity basically can meet the demands of our agricultural production. However, industry and commercial business are shipping large quantities out of the province, causing a great decrease in the available supply of chemical fertilizers in the province.

One reason for the large shipments of chemical fertilizers out of the province is the pricing problem. Comparing the higher price for sales outside the province (167 to 170 yuan for each ton of small nitrogen fertilizer leaving the factory with the lower price for sales in the province (150 yuan each ton leaving the factory), there is a difference of 20 some yuan per ton. Consequently, for the sake of profits as well as certain requirements in operations, the plants and commercial departments are shipping large quantities out of the province. Based on statistics, in 1981 the industry sold 460,000 tons of ammonium carbonate and 230,000 tons of phosphate fertilizers outside the province while the commercial businesses sold 230,000 tons of nitrogenous fertilizers and 33,000 tons of phosphate fertiliers, a total of 950,000 tons. Despite the strengthening of chemical fertilizer control, the industry still sold 230,000 tons outside the province and the commercial businesses sold 170,000 tons, a total of 400,000 tons from January to July of this year. It is estimated that by the end of the year the total sales outside the province will not be below 500,000 tons.

Naturally, if there is a surplus of chemical fertilizers in our province, appropriate support of other provinces is acceptable. However, that is not the situation at present. There is still a supply gap in our province. Based on the statistics for the supply and sales cooperatives system alone, 930,000 tons of chemical fertilizers were shipped into our province from the outside last year and 558,000 tons from January to August this year. On one hand, we are blindly making shipments out of the province and on the other, we are bringing in chemical fertilizers from the outside. This is wasting the state's manpower and materials.

Another reason for the large sales of chemical fertilizers outside the province is our small warehouse capacity and low storage capabilities. The sale of chemical fertilizers is highly seasonal. Basically, the peasants only make purchases when they have to be used. Thus, the storage of the commercial departments is greatly increased, but their storage capacities are very small. During the slack season, the chemical fertilizer storage is as much as 1 million tons. This would require 1 million square meters of warehouse space. But the total space of the entire production system in the province is only 440,000 square meters. The space specially for chemical fertilizers is even more limited. Because of this tight warehouse situation, a lot of the chemical fertilizers have to be stored in the open, resulting in very large damages during rainy weather and affecting the enthusiasm of the commercial departments in the procurement of chemical fertilizers during the slack season.

The above problem increases the contradiction between chemical fertilizer supply and demand during the brisk season. The black market is rampant in some places. For instance, at the Dasong County Fair in Li County, the market for urea during the brisk season is as high as 800 yuan a ton greatly exceeding the specified price of the state. The profiteering elements are making huge fortunes, and the peasant masses have some strong opinions.

To solve this problem, we suggest:

(1) Industry and commerce should both be concerned with the overall situation and the supply and sales of chemical fertilizers should be self-sufficient in our own province. The price of small nitrogenous fertilizers in our province should be rationally adjusted, so that both industry and commerce will realize national operating profits. Outside the fulfillment of the state distribution and transfer tasks, administrative measures should be adopted so that basically there will not be any shipments of chemical fertilizers out of the province. At the same time, the over rigid price control in the province of chemical fertilizers produced outside the plan should be adjusted. Commerce should contract for the sale of all the chemical fertilizers produced by industry. Sales by the industry itself should be eliminated.

(2) The construction of special warehouses for chemical fertilizers should be strengthened. We suggest that the various planning departments place the

construction of chemical fertilizer warehouses in their plans. The supply and sales departments should also actively raise funds, so that warehouses meeting storage needs are gradually constructed within 2 to 3 years. For the moment, a seasonal price differential may also be considered for the small nitrogenous fertilizers, with higher prices during the brisk season and lower prices during the slack season with the overall accounting for the year basically equivalent to the list price. This would motivate the enthusiasm of the masses to store chemical fertilizers.

(3) Market management should be strengthened. We suggest that required management systems be established by the industrial and commercial management departments. Profiteering and speculation and resale of chemical fertilizers at high prices should be strictly banned.

SIX ANIMAL HUSBANDRY PRODUCTION BASES SET UP

Beijing RENMIN RIBAO in Chinese 4 Oct 82 p 1

[Article: "State, Collectives and Individuals Team Up, Give Strong Support to Specialized and Key Project Households; Heilongjiang Province Sets Up Six Animal Husbandry Production Bases"]

[Text] Heilongjiang Province, making use of the advantages of its rich natural resources and in line with local conditions for raising cows, milk goats, cattle, sheep, medium-wool sheep, market hogs and chickens, has set up six different types of animal husbandry production bases. Most of the cities and counties are engaged in animal husbandry, though with different emphasis. The restructuring and building of such bases over the past 2 years have brought along the development of animal husbandry industry throughout the province.

Stress on building animal husbandry production bases was a significant measure adopted by Heilongjiang Province to carry out strategic changes in the agricultural development. The natural conditions of the province are fields intersected by five mountains, a grassland and a river. There are more than 76 million mu of grasslands, grass hills and hillside fields. Songnen Prairie in the west is abundant in alkaline-rich meadows; while Sanjiang Plain in the east grows luxuriant small-leafed camphoric forage grass. Various counties have numbers of scattered grasslands. Each year the province produces more than 500 million jin of bran, 800 million jin of bean cake, 4.4 billion jin of sugar beet. All these help tremendously the development of the animal husbandry industry. In the past, the distribution of agriculture was irrational, the emphasis was one-sidedly placed on grain, and the emphasis, within the industry of animal husbandry, was on "priority on pigs." Breeding of cattle, sheep and other plant-eating animals was neglected, thus animal husbandry slowly developed. Since 1979, by progressively readjusting the distribution of agriculture and the internal structure of the animal husbandry industry, we have achieved noticeable results. As of now, the total number of sheep and poultry in the province has nearly doubled, compared with that of 1978.

The province has given special attention to developing dairy cattle production that the masses are accustomed to and thatis of comparatively high economic value. Three cities, such as Harbin and Qiqihar along the railway line, and four counties, such as Shuangcheng, have been designated as dairy cattle production bases, which will promote the whole dairy cattle industry in the province. Since 1979, the number of cattle in the provincial inventory has been consistently increasing at a 20 percent yearly rate. To date, there are 115,000 cows, 85.5 percent more than that in 1978. Last year the province produced a total of 168,000 tons of fresh milk, 73.4 percent more than that in 1978.

In the production of animal husbandry, Heilongjiang Province has conscientiously implemented the Party Central Committee's policy on animal husbandry development, corrected the tendency of stressing the development of state-woned and collective animal husbandry bases and neglecting the ones owned by the vast peasant and herdsman households. We have succeeded in opening simultaneously "the three doors" of state-owned, collective and individual enterprises, fully mobilizing thousands of agricultural households to participate actively in animal husbandry, and forcefully supporting specialized and major project households.

As of now, 270,000 livestock-raising specialized and key project households have been set up throughout the province. In addition, there are 175 centralized stations breeding chickens, cows and pigs. These stations have become an important strength in leading the vast peasants and herdsmen to a scientific animal husbandry industry.

GREATLY IMPROVED ECONOMIC SITUATION ON STATE FARMS REPORTED

Harbin HEILONGJIANG RIBAO in Chinese 17 Aug 82 p 1

[Article: "New Development of Province's State Farm and Land Reclamation Areas Following 3 Years of Readjustment and Restructuring; Structure of Agriculture Increasingly Rational Day by Day; Marked Rise in Economic Effectiveness; Rapid Development of Economic Diversification; and General Increase in Staff and Worker Earnings"]

[Test] Following the Third Plenary Session of the 11th Party Central Committee, and as a result of 3 years of readjustment and restructuring, certain changes have taken place in the single form of ownership system, the single kind of occupation, the single form of wage distribution system, and the single avenue of employment in Heilongjiang's state farm and land reclamation areas. Since the farm work conference held at the beginning of this year, in particular, greater breakthroughs have occured in work in these regards.

Restructuring of the sole economic form of ownership by all the people has vigorously developed the state-owned economy while actively supporting and developing the collective economy and the individual economy. As of the end of June, the number of collective economic enterprises in the state farm and land reclamation area had grown to more than 1,650, and more than 111,300 dependents and sons and daughters of staff and workers had found places in them. The number of individual households engaged in production of commodities numbered more than 3,000, and the number of industrial and commercial households had also grown to 965. The state farm and land reclamation area had also transferred 2,156 cadres to bring collective enterprises up to strength in a strengthening of the leadership of the collective economy in all its aspects.

Restructuring of the farming system's sole production of grain and beans for active development of economic diversification while positively not relaxing grain production. This year the state farm and land reclamation area's economic crop area amounted to 550,000 mu, a 34 percent increase over last year. The cattle, sheep and goat, poultry, and fish breeding industries also grew by 25 percent over last year. Growing of wood fungus and mushrooms increased by 30 percent over last year. The building of 19 production bases got underway for mountain grapes, hops, black currants, and Chinese medicinal materials. The output value of this year's economic diversification has been estimated at 250 million yuan, an increase to 14 percent from the 6.8 percent ratio to gross output value of 1979.

Restructuring of the single fixed wage system form of distribution for active promotion of various forms of production systems of responsibility. This year, except for a small number of schools and hospitals, the 97 agricultural and livestock farms in the state farm and land reclamation system area, from farm organizations to grassroots level production units, will universally institute a system of basic wages plus fluctuating wages, and the linking of output to the calculation of remuneration in various forms of production responsibility systems for the arousal of the enthusiasm of both enterprises and workers.

Restructuring of the single avenue of employment, with labor departments recommending employment, voluntary organization of employment, and finding employment by oneself in a three-way program of employment to broaden employment avenues.

Up until 1979, the state farm and land reclamation area operated at a loss for more than 10 years, and economic diversification fluctuated from 6 to 10 percent of gross output value. Changes in the "four soles" economic situation has meant that for the past 3 years, except for last year when serious disasters entailed operating losses, profits rose for the 2 consecutive years of 1979 and 1980, the total figure amounting to 561 million yuan. This year the ratio of value from economic diversification to total output value broke 10 percent, and in one farm management bureau and two farms it reached or exceeded 20 percent. Because of the greater number of employed sons and daughters, increase in income from household sideline occupations, and increased bonuses, average per capita income increased from 239 yuan in 1977 to 343 yuan in 1981, a 43.5 percent increase.

PROGRESS IN AGRICULTURAL PRODUCTION VIEWED

Beijing RENMIN RIBAO in Chinese 29 Oct 82 p 1

> [Text] Editor of XINHUA: For several years, the agricultural development situation in Henan Province has been delightful. The speed of yield increase of Henan and some other provinces shows that China's agricultural production has a very great potential and the prosperous development of rural villages has just got started. Reading the following report from Henan should help strengthen people's confidence in creating a new breakthrough in agriculture.

Since the Third Plenary Session of the 11th Party Congress, the rural villages of Henan Province have seriously implemented the various economic policies of the party and practiced various forms of an agricultural production responsibility system. A positive feeling has been aroused among the farming masses. Every year, there have been yield increases in grains, cotton, oil, and tobacco in the entire province. The situation in the rural villages is better and the livelihood of farmers is improving, year after year.

According to the information supplied most recently by the Henan Provincial Bureau of Statistics, the total value of agricultural products of the province in 1981 (calculated in the constant price [yuan value] of 1970) reached 121.3 billion yuan, an increase of 22.8 percent over that of 1978, averaging an annual increase of 7.1 percent. Compared with the average annual increase of 3.4 percent of the 26 years of 1952-78, the increase is more than twice as fast. The average net income of commune members of the province in 1981 reached 215.6 yuan/person, more than doubling that of 1978. With the production development and income increase, the members' consumption of grains, oil, meat, and eggs grew in leaps and their housing conditions obviously improved. Now, the farming masses have left behind the life of poverty of "sweet potato soup and sweet potato bread; no living without sweet potatoes." They are living a rich life of "a house with a tiled roof, eating fine grain, and having money left in the bank." In this province of historically frequent disasters and low production, the influence of leftism has been cleared away since the Third Plenary Session of the 11th Party Congress and the internal structure of agriculture readjusted. While earnestly attending to grain production, diversified operation has been urgently pursued to guarantee yield increases in grain, cotton, oil, and tobacco year after year. According to statistics, the total grain production of the province in 1981 was 46.3 billion jin, an increase of 10.4 percent over that of 1978, averaging an annual increase of 3.3 percent in these 3 years; it has increased faster than the average annual increase of 2.9 percent for the 26 years from 1952 to 1978, to create the highest historical record of total production. On the basis of last year's abundant harvest of summer grains, this year's summer grain production was further increased to reach a total of 22.7 billion jin. Compared with the production of 1978, the total cotton production of the province in 1981 grew 58.4 percent, that of tobacco 29.8 percent, that of rapeseed 1.3-fold. Compared with the rapeseed production of 1981, the production this year was 33.5 percent higher. At the end of 1981, the number of large animals in the stalls all over the province exceeded the highest record in history.

The contribution of Henan Province to the country is becoming greater and greater.

PROVINCE PEASANTS' LIVING STANDARD INCREASES

Nanjing XINHUA RIBAO in Chinese 23 Sep 82 p 2

[Article: "Good Policy Brings Good Living; The Life of the Peasants of our Province Has Distinctly Improved"]

[Text] Since the Third Plenary Session of the 11th Party Central Committee, with a series of economic policies of our party put into full effect, our province's agricultural production has achieved considerably rapid development and the peasants' life has shown distinct improvement. The following are the survey statistics of 1,000 commune households' income, by the Provincial Statistical Bureau:

In 1981, the average net income per capita was 258 yuan, 103 yuan more than that of 1979, which was 155 yuan, increasing progressively at an 18.5 percent yearly rate.

The percentage of average net income of over 300 yuan among the surveyed households rose from 5.4 percent in 1978 to 33.3 percent in 1981; while the percentage of average net income of less than 100 yuan dropped from 26.4 percent in 1978 to 1.3 percent in 1981. Compared with 1978, the 198. consumed grain ration per commune members has had, on an average, an increase of 16 jin, consumed cooking oil increased 2 jin, meat 6.1 jin, eggs 1 jin, seafood 1.7 jin, and wine 2.2 jin. The quantity of wool and silk fabric and fine wool purchased has increased respectively 8.2, 6.9, and 2.6 times compared with 1978.

In 1981, in terms of the "four big items," every hundred commune households have, on an average, 41.7 bicycles an increase of 21.7 more compared with 1978; 18.5 sewing machines--9.5 more compared with 1978; 46.1 radios--34 more; and 108.1 watches--57 more than in 1978.

During the 3 years of 1979-1981, 29.6 percent of the surveyed households have built new houses. Since 1981, every family has, on an average, 3.9 rooms, 0.3 room more than in 1978. The living space per capita has reached an average of 11.2 square metre. Of the current housing the space of brick and wood structure has increased to 70.3 percent from 54.7 percent in 1979.

MARKED INCREASE IN RURAL INCOME REPORTED

Beijing RENMIN RIBAO in Chinese 19 Sep 82 p 2

[Article: "Marked Increase in Rural Jiangsu Average Per Capita Distributed Income; Responsibility Systems Changes High Cost Low Benefit Situation in Agriculture; Province's Collective Distributions in 1981 Averaged 130.39 Yuan Per Capita; Annual Increase in Income Distributed to Commune Members 11 Times Greater Than Average Annual Increases During Past 21 Years"]

[Text] In Jiangsu Province, where agricultural production has developed rapidly yet commune member income has increased but little, in 1981 overall costs in agriculture fell for the first time and net income increased tremendously in a heartening situation. Counties (or municipalities) in the province having average per capita distributions of more than 200 yuan numbered one-fifth of the total, and the number of wealthy production teams with incomes per capita of more than 300 yuan doubled over 1980. Annual increase in income distributed to commune members was 11 times greater than average annual income increases during the past 21 years.

Statistics from departments concerned show that in 1981 average per capita collective distributions amounted to 130.39 yuan, 24.31 yuan more than during the previous year, for a 22 percent increase. Counties (or municipalities) with per capita incomes of more than 200 yuan spurted from the five of the previous year to 16. Wealthy production brigades and production teams in which per capita distributions were more than 300 yuan rose from the previous year's 249 and 2,128 respectively to 682 and 4,311.

The level of agricultural production in Jiangsu Province has always held a leading position nationally. However, owing to failure to give attention to cost accounting and poor administration and management, in the 21 year period from the beginning of cooperativization in 1978 speed of increase in overall agricultural costs greatly exceeded speed of increase in total earnings. During the past 21 years, average per capita peasant income has increased annually by only 2.20 yuan.

After Jiangsu Province conscientiously put into effect the party's various rural economic policies, the not very fast increase in commune member distributed income changed. All prefectures first of all adapted general methods to local situations in a readjustment of crop patterns for grain and economic crops, and comprehensively developed farming, forestry, livestock raising, sideline occupation, and fishery production. By 1981 forestry, livestock raising, sideline occupation and fishery output value already accounted for 44.6 percent, or nearly half, of the province's gross output value from agriculture. In 1981, for the first time the province's gross income from agriculture broke the 11.1 billion mark, which was 1.26 billion yuan or 12.8 percent more than 1980 to create an all-time high. Total agricultural production costs fell for the first time, declining by more than 100 million or 2.5 percent from 1980. Establishment and perfection of production responsibility systems played a key role in the tremendous increase in commune member income. In 1981, more than 71 percent of production teams in the province established "double contracting" [contracting of production and work tasks] responsibility systems linking remuneration to output, and made improvements in agricultural administration and management. Statistics show an 89 million yuan decrease from 1980 in production costs for the province as a whole.

Institution of agricultural production responsibility systems also overcame and reduced the problem of rash spending and subsidies on the part of the collective, gorging on food and drink, and inviting guest and sending gifts at the expense of the collective. Such miscellaneous expenditures fell by 24.6 million yuan in 1981 as compared with 1980 for a 9.9 percent decline.

PROVINCIAL NOTICE ISSUED ON FALL PLANTING

Jinan DAZHONG RIBAO in Chinese 10 Sep 82 p 2

[Article: "Provincial People's Government Issues Notice on a Further Good Job of Fall Planting. Planting of Wheat in Sufficient Amounts and Well Under the Inspiration of the Spirit of the 12th Party Central Committee"]

[Text] The Provincial People's Government recently issued a notice on doing a further good job of fall planting, which called upon all jurisdictions to arouse the broad masses of cadres and people under inspiration of the spirit of the 12th Party Central Committee to do a solid job of planting wheat in sufficient quantities and well.

The "Notice" required the following:

1. Making sure that planned fall planting areas are planted. The 55 million mu fall planting area that the provincial government has handed down this year was set with readjustments made in the structure of agriculture during the past several years in mind and following study of current actual circumstances in the province as a whole. The planting area assigned each jurisdiction should be fulfilled as figured, and efforts made to exceed the figure. This fall the soil moisture situation is fairly good in most parts of the province. This is beneficial for fulfillment of fall planting plans, and all conditions are at hand for timely planting of more wheat. In Shandong Province where population is large relative to available land, food is a matter of primary importance. Wheat is the province's major grain crop, and the amount of commodity wheat production is large. How good the wheat harvest has an extremely great bearing on fulfillment of the province's grain output plans and state purchase quotas. Today the conflict between supply and demand for grain in the province is pronounced, and use of every available means to achieve a large grain harvest next summer has become an issue of major importance. In order to increase wheat output very greatly, it is necessary, of course, to try to increase yields per unit of area. However, unless a sufficiently large area is planted, this will not work. Reportedly several prefectures (particularly northwestern prefectures of the province where economic crops are concentrated) plan to plant an area far less than that provided for in provincial plans. In all places in which plans have not been well implemented, conscientious efforts should be made to indoctrinate cadres and masses, proceed from the situation as a whole, and make all around arrangements for grain and economic crops keeping all factors in mind.

2. Efforts should be made to improve quality of fall planting. There should be a conscientious summarization of experiences with increased wheat output for many years in the past, a firm grip taken on measures to increase output including water, fertilizer, soil, seeds, and closeness of planting, and efforts made to plant as early as possible. Extremely close attention should be given to preservation of soil moisture, guarding against drought before drought occurs, creating soil moisture when drought occurs, and doing unified planning taking all factors into consideration in harvesting, sowing, and tending the crops, clearing away the stubble of the previous crops and plowing the soil at the same time to insure earliest possible sowing. Every available means should be used to enlarge the irrigated area, superior varieties selected on the basis of adaptation of general methods to local situations, maintain high standards, and strictly require fulfillment of fall planting quotas.

3. More good work in the supply of materials. Railroad and transportation departments should make priority arrangements for the hauling of the chemical fertilizer, pesticides, seeds, and farm machinery and implements required for fall planting. Right now the shortage of diesel fuel is a prominent problem, and the state is currently unable to increase allocation norms. All that can be done is to conserve use of diesel fuel stringently, making sure that it is used only where absolutely necessary. Where tractors are being used for hauling as a business, the practice must be decisively stopped. Wherever some fuel can be squeezed from use by commune and brigade industrial sideline enterprises, it may be used in fall planting. Insofar as possible, an increase in electric power load should be allocated for agriculture to support fall planting in an effort to plant wheat in sufficient quantity and well.

4. Actual leadership of fall planting work should be strengthened. Rural villages are about to enter the extremely busy stage of the three autumn jobs [harvesting, plowing, and sowing]. Opportunities cannot be missed, for the time once gone will never return. In every task, the extremely busy season in farming has to be taken into consideration with unified planning that takes all factors into consideration being done and all-around arrangements being made under leadership of CPC committees. Prefectures, counties, and communes should organize large groups of cadres to go down into the country-side to study the 12 major documents with the masses and do a good job of fall planting. Serious attention should be devoted to the rule of agricultural science and technical personnel to raise the level of scientific farming. Production responsibility systems should be perfected, and contract agreements entered into providing for production, sales, withholdings, rewards, and penalties. Attention should also be given help to the small number of hardship households in planting wheat. In flatland areas along the Huang He and in lake areas, all difficulties should be overcome to plant wheat in sufficient amounts and well so as to buttress the confidence and capacity of the masses to provide for and help themselves by engaging in production.

AUTUMN PLANTING NEARLY COMPLETED

Jinan DAZHONG RIBAO in Chinese 14 Oct 82 p 1

[Text] A responsible member of the provincial committee spoke to this reporter yesterday that planting of more than 50 million mu of autumn wheat has been completed in the province and the cadres and commune members of rural villages are making continuous efforts to round up what work remains to be done to guarantee the quality and the quantity of the 55 million mu autumn planting plan of the province. This committee member said that this year the party committees and governments of all levels in the province have emphasized the autumn planting work. The masses have been fully mobilized to learn to implement the 12 great spirits of the party. The revolutionary will and passion for labor of the cadres and masses thus aroused form an effective push for the development of the autumn planting work. At present, aside from the four prefectures of northwestern Shandong which concentrate on cotton production, the planting plans distributed by the province of the other nine prefectures and cities have been basically completed. Not a few units are encouraging the masses to expand the wheat acreage.

Compared with the autumn planting of last year, this year's planting has the following major characteristics: Firstly, it got started earlier and progressed faster. Due to the fact that this year's summer planting was earlier, the autumn crop matured earlier so that the harvest, plowing, and planting time was all generally earlier than last year. Before the national holiday, 31 million-plus mu of wheat had been planted, 11 million mu more than the same time last year. Secondly the foundation was good and the quality was high. The soil moisture condition this year was better than at the same time last year. The quantity of farm fertilizer applied this year was about the same but the quality was better and the quantity of chemical fertilizer applied was obviously more than last year. Calculating on the basis of the quantity of fertilizer prepared and the actual acreage planted, on the average 45 jin of nitrogen chemical fertilizer and 60 jin of phosphate fertilizer were applied per mu. In the cotton region, there was an additional application of 30-plus jin of residue cake per mu. The land was intensively worked and leveled and the machine-plowed and machine-planted acreage was 20 to 30 percent larger than last year. Mounds were built in all wheat fields that were to be irrigated. By now, 36 million mu of the wheat fields that have been seeded have germinated and the seedlings appear to be complete and in good shape in most of these fields. Thirdly the system of wheat production responsibility was implemented early and well. When the autumn planting plan was being formulated in the various areas the wheat production responsibility system was worked out at the same time and production contracts were signed almost everywhere. The relationship of unity [in planning] and division [in responsibility] was also well handled. Fourthly there was an obvious improvement in scientific cropping. Technical training was carried out in all the areas. In most cases, training classes of various levels were organized before autumn planting. According to incomplete statistics, more than 700,000 cadres and farmers of communes and brigades participated in these training classes. More than 80 counties in the province practiced the agricultural technology responsibility system to take care of more than 3 million mu of wheatfields, more than doubling the acreage last year. Based upon the change in the condition of fertilizer and water, the various areas also changed the wheat breeds to cause the breed arrangement to be basically reasonable. In a word, the autumn planting work in the province has been performed relatively well this year, but there remain some problems. A few areas and units arranged less acreage than the planting plan distributed by the province, to result in a total shortfall of 1 million mu. In the cotton production region, the planting work progressed slowly. Some units have completed only half of their planting tasks. In some areas, the drought persists and it has become more and more difficult to carry out drought-resistant planting. Moreover, due to severe drought, germination of some wheat fields is not complete and the condition of missing seedlings is relatively serious. The provincial committee member pointed out that now that Cold-dew [8 Oct] is over, even with the relatively high temperature, there is not much suitable time left for wheat planting. All the areas should strengthen the leadership still further to finish whatever work remains to be done to guarantee the completion of the 55 million mu autumn planting plan of the province. For those units which progress slowly, the leadership, by all means, should be concentrated for an all out assault to speed up planting. In areas of concentrated cotton production, there should be an overall planning to resolve the labor contradiction of cotton harvest and autumn planting. Measures must be adopted to hurry up with the work of uprooting and turning over the stubble so as to plant sufficient wheat to meet the requirement of the state's plan. Areas and units suffering from severe drought should continue to mobilize the masses to carry out the drought resistance struggle. The soil should be moistened according to the actual condition of each locality before planting, or the method of seeding first before watering should be adopted to complete the autumn planting task before Hoar-frost-descends [23 Oct]. Those units that have completed or basically completed the autumn planting task should try to enlarge the wheat acreage as much as the condition permits. The wheatfields that have been seeded should be managed in a timely manner. Wherever the soil is deficient in moisture, supplementary water should be applied; wherever the seeds have germinated, the seedlings should be carefully inspected and thinned if they are too dense and supplemented if they are not dense enough. The tillering water should be duly applied. Attention should be given to prevention and control of ground pests to guarantee complete and strong seedlings to form a good foundation for next year's good harvest.

PROVINCE'S IMPOVERISHED PREFECTURES POST PROGRESS

Jinan DAZHONG RIBAO in Chinese 15 Sep 82 p 2

[Article: "Tremendous Changes in Four Northwest Shandong Prefectures in 3 Years; Third Plenary Session Policies Good; Becoming Prosperous Requires Full Reliance on Party Leadership"]

[Text] The four northwestern prefectures of Shandong, which were the very first in the province to institute the responsibility systems of "contracting output quotas to households" and "contracting work tasks to households," have readjusted their agricultural crop patterns over the past 3 years to make the most of advantages for the growing of cotton. As a result, gross income from agriculture has more than doubled, and commune member distributed income has almost tripled. The broad masses of cadres and people have termed the spirit of the Third Plenary Session of the 11th Party Central Committee "a pleasant rain after long drought."

Heze, Liaocheng, Dezhou, and Huimin prefectures located in northwestern Shandong consist of 13 counties with an agricultural population totaling more than 21 million and more than 41 million mu of cultivated land. Population and cultivated land area amount respectively to one-third and 40 percent of the province's total. During the more than 20 years prior to the Third Plenary Session of the 11th Party Central Committee, these four prefectures consumed a total of more than 7.1 billion jin of grain sold at a uniform price, incurred debts to the state amounting to more than 600 million yuan, and spent more than 800 million yuan of national relief funds. Since the Third Plenary Session, tremendous changes have occurred in the situation here. Major differences between 1981 and 1978 explainable in figures were as follows:

Total cotton output rose from somewhat more than 1.89 million dan to somewhat more than 10.97 million dan.

Gross income from agriculture amounted to 4.39 billion yuan, up 103.95 percent.

Average per capita collective distributions reached 138.80 yuan per year, a 92.10 yuan increase and more than 10 percent higher than the average for the province as a whole. On average, every 10 commune member households had 9.6 bicycles, 4.3 sewing machines, 4.5 wristwatches, 7.1 radios, and about one-third of all peasant households built new tile-roofed houses. Bank savings accounts increased 6.7 fold.

Contributions to the country have become greater and greater. Over a 3-year period they sold the state a total of more than 21 million dan of cotton, more than 900 million jin of grain, plus large quantities of furs, meats, and timber.

Collective accumulations have increased steadily, public accumulation funds amounting to 132 million yuan for a 40.4 percent increase. Collective grain reserves amounted to more than 26 million jin. The number of farm machines has increased greatly, and the amount of collectively owned fixed assets has risen.

BRISK RURAL MARKETING ACTIVITIES IN TAIAN PREFECTURE

Jinan DAZHONG RIBAO in Chinese 10 Sept 82 p 2

[Article: "Adhere to the Principle of Taking the Planned Economy as the Key Link With Market Regulation Being Supplementary; Taian Prefecture Supply and Marketing Cooperative Staff and Workers Study 12 Major Documents; Look to Future With Full Confidence at Being Able To Do a Good Job of Rural Market Busy Season Purchase and Marketing Work"]

[Text] Taian Prefecture supply and marketing cooperative cadres, staff, and workers have assiduously studied the 12 important documents for further correct understanding and implementation of the principle of taking the planned economy as the key link with market regulation being supplementary, and to take action to do a genuinely good job of market busy season purchase and marketing work.

In the course of studying the 12 important documents, the supply and marketing cooperative cadre, staff, and workers in this prefecture related the study to supply and marketing work realities in the prefecture, and reviewed the achievements that have been won since the Third Plenary Session of the 11th Party Central Committee. In the period between 1979 and 1981, Taian Prefecture supply and marketing system procurement of agricultural sideline products has risen from a total figure of 94 million yuan to 128.12 million yuan, and average annual sales of agriculture sideline products to the state have risen from 16 yuan to 25 yuan. Rural business sales figures for the prefecture have gone from 440 million yuan to 491.6 million yuan for giant strides in a 3 year period. Quantities of major agricultural sideline products purchased such as cotton, fruits, mulberry silkworm cocoons, honey, jute, santiao [0005 2742], livestock products, and manufactures made of reeds, and quantities of industrial products marketed such as bicycles, wristwatches, wall clocks, television sets, radios, and chemical fiber cloth set all-time highs. The broad masses of cadres, staff and workers look ahead with confidence and strength at the bright prospects for socialist business, determined to understand better and carry out the principle of taking the planned economy as the key link with market regulation being supplementary to do a better job of rural commercial work.

Rural markets are now entering the busy season, and mountain area building endeavors will also soon start an upsurge. Taian Prefecture supply and marketing cooperatives have decided to invest nearly 1 million yuan in support of production in mountain regions to help communes and brigades develop economic diversification. One-third of the funds are to be used for the planting of resources; one-third is to be used in scientific and technical experiments; and one-third is to be used in product processing. Ten dry fruit [nuts and condiments] bases, 10 fresh fruit bases, five livestock bases, and three tiaozi [2742 1131] bases are to be built. In addition, no opportunities will be lost to take a firm grip on procurement of agricultural sideline products, notably cotton and fruits. By sending goods into the countryside, extending wholesale points into the countryside, through the use of state-supplied joint business ventures, and the conversion of shops acting as agents for purchases and sales to businesses run by production teams themselves, by keeping channels open, and by organizing dispatch to the countryside of industrial products, a good job of supplying the means of production for the "three autumn jobs" [harvesting, plowing, and sowing] will be done. Day after day regional supply and marketing cooperative leaders have held continuous vocational meetings of supply and marketing cooperatives in each county, and they have gone to prefecture native products stations, means of production stations, and cotton and hemp stations to inspect the situation and formulate specific programs. They have also assigned seven people to organize work teams to be sent to Xintai, Ningyang, and Xinwen counties to gain an understanding of the situation regarding support to the construction of mountain regions, and to urge on development of supply and marketing activities. According to incomplete statistics, between 1 and 4 September the prefecture's supply and marketing system sent 3,500 shipments of goods into the countryside, marketed 15.2 million yuan worth of goods, and purchased agricultural sideline products to a total value of 5.72 million yuan.

BRIEFS

RECORD DOMESTIC ANIMAL BREEDING--The Animal Husbandry Department of Huimin Prefecture established and perfected a large domestic animal breeding economic responsibility system to allow the three indices of mating, insemination, and birth to reach the highest level in the prefecture's history. They first reorganized the 37 state-operated and commune-operated domestic animal breed improvement stations. Following reorganization, a detailed work rule was formulated for each station to establish and perfect an economic responsibility system for each job and to award prizes of mating and insemination classes to encourage the cadres and technicians to be positive. The Fuguo Breed Improvement Station of Zhanhua County established an insemination point in Yongfeng which is rather far from the station, and every day technicians traveled 40 li to the insemination point to meet the animal breeding needs of the masses. In the first half of this year, more than 1,600 female animals were inseminated, a 2-fold increase over the entire year last year. The 17 state-operated animal breed improvement stations of the prefecture have all surpassed last year's records in the number of animals inseminated and the number of successful pregnancies. Private households raising stud animals are identified, registered, and certified by the commune animal husbandry and veterinary medicine department and provided with a certificate to allow mating participation. The prefecture now has 120-plus households thus certified and they raise more than 150 studs to inseminate 9,360 female animals, amounting to 18 percent of all female animals inseminated in the entire prefecture. [Text] [Jinan DAZHONG RIBAO in Chinese 13 Oct 82 p 1] 6248

COTTON OUTPUT--Once more the cotton harvest in the province has been good this year. The cotton crop is growing very well everywhere and there is a general yield increase. The cotton farmers are happily picking the new cotton, on the one hand, and negotiating sales and deliveries to the state, on the other. Middle summer bolls are numerous and boll openings concentrated so that the cotton purchase has arrived ahead of time. By 10 October, the daily purchase quantity reached 300,000 dan and in the province 6,231,000 dan of ginned cotton had been bought, 1.39-fold of the same period last year. In order to carry out the cotton purchase realistically and well, the leaders of the various cotton-producing areas have cooperated closely with related departments and tried to perform all items of work well. The Weifang Prefecture extended, with all out efforts, the method of using the production team or several teams together as a unit seller and relatively good results have been obtained. This method basically resolves the problem of cotton purchase difficulty. After the implementation of the joint production responsibility system in such counties as Gaotang, Linqing, Xiajin, Huicheng, etc, with respect to cotton production, the new condition of a growing number of households selling separately has occurred and the work of designating fixed time, place, and lots for balanced purchases and deliveries is being earnestly carried out. Under the guidance and support of the local party committees and governments, many purchase stations are also urgently organizing short distance transport of cotton for timely delivery of the purchased cotton to the cotton processing plants. [Text] [Jinan DAZHONG RIBAO in Chinese 13 Oct 82 p 1] 6248

HIGH YIELD CORN VARIETY--Li Denghai [2621 4098 3189], the national new long march assault specialist and the head of the agricultural science team of the Houdeng Brigade of Xiyou Commune and his friends bred out the corn superior variety, Yedan No 2. This year, it produced a very good harvest over a large area. The provincial, prefecture, and county science and technology departments acknowledged, after on-site inspection and receipt most recently, that the yield of the 10,480 mu of corn averaged 1,072 jin/mu. According to the specialists who came to the inspection, this kind of high corn yield over such a large area is unprecedented in the country. This result has presented a delightful prospect for future large-scale increase of unit yield of direct seeded corn. Li Denghai and his friends of the agricultural science team worked very hard for 7 years to select and breed out in 1979 this new superior breed of corn, Yedan No 2. It has good stalk shape; the weight of the grain is high. It is resistant to Helminthosporium leaf spot disease of corn, suitable for dense planting, and highly adaptable. It has produced 1,807.7 jin/mu as spring corn and 1,613 jin/mu as summer corn respectively to create the high yield record of corn in north China and received the provincial science and technology award. Tests by some scientific research units and commune-brigades of 24 provinces, cities, and autonomous regions have all produced yields of above 1,000 jin/mu. This year, it is used for the 10,480 mu of corn of all the 18 brigades of Xiyou Commune. Under the guidance and with the help of the supervising science and technology department, they designed a complete set of scientific management program to strengthen the management of the corn crop to apply nitrogen, phosphorus, and potassium in a coordinated manner, to apply water in a timely manner, and to exterminate pests. With the joint effort of cadres and masses, serious drought and pest calamities were overcome to produce the large area high yield result. [Text] [Jinan DAZHONG RIBAO in Chinese 13 Oct 82 p 1] 6248

TITLE: "Effects of the No 4 Typhoon in 1977 on the Heavy Rainstorm over North China"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 2, May 82 pp 1-8

TEXT OF ENGLISH ABSTRACT: In this paper, a detailed analysis is presented to show the effects of the No 4 typhoon of 1977 on the heavy rainstorm in Hebei and Liaoning provinces of north China. It was found that during the late summer the landed typhoon along the east coast of China caused a hard rainstorm on north China mainly through the low-level SE jet between the typhoon and the Pacific subtropical high. This low-level jet was an important interaction link between the typhoon and the west trough. It not only transported a large amount of water vapor and led to vapor convergence, but also formed energy grontogenesis along the shear line of the middle-low troposphere and provided convective instability energy which is necessary for the mesoscale convective activity.

[Continuation of BEIFANG TIANQI WEN JI No 2, May 82 pp 1-8]

In addition, there was inhomogeneity of the low-level jet in time and space and, in particular, there were south wind pulses on the low-level jet. These south wind pulses propagated northward along the low-level jet and directly triggered the generation and development of mesoscale system.

Finally, according to the interaction between large and mesoscale systems, it is emphasized that the interaction of middle- and low-latitude large-scale systems is very important for the short range forecast of hard rainfall.

TITLE: "A Study of the Condition of the Occurrence of Convective Rainstorm at the Northwestern Subtropical High in North China in Summer"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 2, May 82 pp 9-18

TEXT OF ENGLISH ABSTRACT: In this paper a case of a convective rainstorm on 5-6 August 1977 at the northwestern subtropical high in north China is analyzed diagnostically with data of sounding for 3 days. The mesoscale features of convective rainstorms are revealed.

It is shown that the abundant water vapor and interaction between cold dry current and warm moist current will cause the formation of mesoscale vortex and then the rainstorm occurs.

The early day's features of wind, temperature and moisture field are shown and the suitable physical conditions of the background are summarized. It is also shown that the small Ri-parameter and $T-T_d<3^\circ C$ existing in the whole air column are favorable macroscopic conditions for the rapid increasing of the small water drop.

TITLE: "Some Climatic Characteristics of Hailstorms and Heavy Rainstorms in China"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 2, May 82 pp 31-39

TEXT OF ENGLISH ABSTRACT: In this paper, the climatic analysis of the hailstorms and heavy rainstorms in China is made. It is found that a heavy rainstorm often occurs in eastern China and a hailstorm in western China. With seasonal variation, the maximum frequency of the latter is about 1 month earlier than that of the former. It is indicated that hailstorms often occur in the region between the polar cold air mass and modified cold air mass in middle latitude, but heavy rainstorms occur in the region between the modified cold air mass in the middle latitude and the tropical warm moist air mass.

TITLE: "A Method for Predicting the Occurrence of Huang-Huai Cyclones* by Discriminant Analysis"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 2, May 82 pp 84-90

TEXT OF ENGLISH ABSTRACT: The method for predicting the occurrence of Huang-Huai cyclones by discriminant analysis is formed on the basis of the practical forecast. First, the data of the multidimensional predictor should be projected according to Fisher criterion on a plane, on which the boundary between the occurrence and non-occurrence of the cyclone should then be decided. The forecast according to the decision boundary is superior to that made with a single linear discriminant function.

TITLE: "Understandings From the Prediction of Extremely Heavy Rainfall in East Hebei on 28 Jul 79"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 2, May 82 pp 114-117

ABSTRACT: A heavy rainfall, as much as 430 mm in some places, occurred in the early morning of 28 Jul 79 in E. Hebei. A forecast map (Fig 1) made by the author, 24 hours prior to the rain, with TAO Zuyu [7118 4371 6877] MENG Guangli [1322 1684 4409] of Beijing University and LIU Chunzhen [0491 2504 5550] ZHANG Fuyuan [1728 4395 0337] of Meteorology Group, Ministry of Water Conservancy participating, coincides very well with the rainfall report issued by the State (Fig 2) in terms of the areas of distribution of the extraordinarily heavy rain. The paper reports the procedure used for the forecasting. Based upon an analysis of the rainstorm formation situation in the vicinity and the Mongolian low eddy, the position of the 300 mb jet stream and the center of the 700 mb up current were taken into consideration. The uplifting action of the southern slopes of Yanshan Mountains on the southeastly of the Bahai Bay was estimated; the cloud scan of the Japanese satellite GMSI and Japanese weather forecasts for 26 and 27 of Jul were used as references for the authors to pinpoint the center of the rain in the area to the north of Tangshan. A method summarized by the authors to forecast effectively the localized rainstorms in the month of Aug in Beijing is mentioned in the paper but not actually introduced.

TITLE: "A Brief Report of the Weather During the Flood of Autumn 81 in the Upper Reaches of Huanghe"

SOURCE: Beijing BEIFANG TIANQI WEN JI [WEATHER IN NORTH CHINA] in Chinese No 3, May 82 pp 120-122

ABSTRACT: Following a dry spell in early Aug, starting on 13 Aug, it rained continuously almost without interruption in the upper reaches of Huanghe. By early to middle Sep, the flood of the region was the worst ever, according to actual hydrological records. The hydroelectric power station, Longyanxia, then under construction and the vast region of both banks of Huanghe in Qinghai, Gansu, Ningxia, and Nei Meng were seriously threatened. The paper does not mention the extent of the damage, however. The meteorological situation, in the 3 periods of late Aug, 30 Aug to 7 Sep, and 8-14 Sep, is briefly reported. The flood receded a few days after the rain stopped,finally, on 14 Sep. The total rainfall in the month, the average 500 mb situation, the major low pressure centers, and the rate of flow in Maqu Gansu in units of m/sec are reported in graphs in the paper.

FBIS FOREIGN BROADCAST INFORMATION SERVICE

NOTE

JPRS publications contain information primarily from foreign newspapers, periodicals and books, but also from news agency transmissions and broadcasts. Materials from foreign-language sources are translated; those from English-language sources are transcribed or reprinted, with the original phrasing and other characteristics retained.

Headlines, editorial reports, and material enclosed in brackets [] are supplied by JPRS. Processing indicators such as [Text] or [Excerpt] in the first line of each item, or following the last line of a brief, indicate how the original information was processed. Where no processing indicator is given, the information was summarized or extracted.

Unfamiliar names rendered phonetically or transliterated are enclosed in parentheses. Words or names preceded by a question mark and enclosed in parentheses were not clear in the original but have been supplied as appropriate in context. Other unattributed parenthetical notes within the body of an item originate with the source. Times within items are as given by source.

The contents of this publication in no way represent the policies, views or attitudes of the U.S. Government.

PROCUREMENT OF PUBLICATIONS

JPRS publications may be ordered from the National Technical Information Service, Springfield, Virginia 22161. In ordering, it is recommended that the JPRS number, title, date and author, if applicable, of publication be cited.

Current JPRS publications are announced in Government Reports Announcements issued semi-monthly by the National Technical Information Service, and are listed in the Monthly Catalog of U.S. Government Publications issued by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

Correspondence pertaining to matters other than procurement may be addressed to Joint Publications Research Service, 1000 North Glebe Road, Arlington, Virginia 22201.

IMPROVE AGRICULTURAL PRODUCTION RESPONSIBILITY SYSTEM URGED

Beijing NONGYE JINGJI WENTI [PROBLEMS IN AGRICULTURAL ECONOMICS] in Chinese No 10, 23 Oct 82 pp 12-15

[Article by Liu Xumao [0491 4872 5399], Commune and Brigade Industries Management Bureau, Ministry of Agriculture, Animal Husbandry and Fishery]

[Text] The various areas implemented the spirit of the "Summary of the National Rural Work Conference" issued by the Party Central Committee, further improved and developed the agricultural production responsibility system and performed a large amount of excellent work. According to statistics through the end of June this year, 99 percent of the production teams throughout the country had introduced the responsibility system, with 90 percent or more of them following the responsibility system of compensation linked with output and 74 percent of them also following that of "double contracting" by households. After 2 years of major reforms, China's rural production relations have been basically readjusted and large-scale changes are things of the past. The responsibility system in various forms has activated the enthusiasm of the hundreds of million peasants, enabling our broad rural villages to continue output increase and flourish, thereby creating an excellent situation. With the free will of the masses and the guidance of the leadership, the readjustment of the rural production relations this time, as indicated by numerous facts, was necessary and sound, favorable to production and compatible with the basic socialist principles.

While the responsibility system pursued in the past 2 plus years has resulted in great achievements, it does not mean that the readjustment of rural production relations has concluded. To perfect the various forms of the responsibility system, we must still perform protracted arduous and careful ideological-political, organizational and research work. Like guiding the agricultural cooperative movement in the past, we must concentratively study and solve the problems in perfecting and improving the agricultural production responsibility system. Therefore, we must, in our guiding ideology, be prepared for a protracted effort in the pursuit of the agricultural production responsibility system. It is a necessity in our endeavor to perfect it and learn the historical lesson of failing to follow up the agricultural cooperative movement with the work of stabilizing, consolidating and improving. We must clearly realize that it is absolutely impossible for such a tremendous and profound change as introducing the agricultural production responsibility system to be accomplished by one stroke. We must, with the development of production, continuously summarize the experiences, spread the good and avoid the bad and further perfect and improve it.

According to the practice of introducing the responsibility system in the past 2 or 3 years and the experience of the past winter and spring, the solution of the following main issues must be stressed in order to perfect and improve the responsibility system.

I. Improve Understanding and Correctly Handle the Responsibility System

Perfecting and developing the responsibility system will inevitably lead to this or that kind of ideological problems. Today, we must guard against two incorrect tendencies: On the one hand, some people feel that, since the enthusiasm of the peasant masses is so high and steady, the task of perfecting the responsibility system has been completed. On the other hand, there are those who regard the new things in the old framework. The moment both unification and dispersal, and unification on the basis of contracting are mentioned, they immediately think of the "leftwing" things of the past. If the first tendency is not overcome, the work of stabilizing, perfecting and developing the responsibility system is out of the question. If the second tendency is not corrected, it will surely dampen the enthusiasm of the peasants.

There are three basic requirements to stabilize and perfect the responsibility system: The first is to have a clear direction, compatible with the principle of "adherence, consistency and consideration." The second is to promote the development of production, increasing both output and income, improving labor productivity and enhancing the commodity rate of products. The third is the free will of the masses and compatibility with the needs and demands of the local people.

In regard to stabilizing and perfecting the responsibility system, some people feel that, "to stabilize, perfection cannot be sought; to perfect, stability is difficult to attain." This view is one-sided and incorrect. As proved by experience, stabilizing and perfecting are mutually complementary. The basic stability of the current responsibility system will provide experience and benefit further perfection. Only when the responsibility system is perfected and production further developed will there be the necessary stability. In other words, the responsibility system must be perfected in the course of stabilization and stabilized, developed and improved in the course of perfecting. The peasants fear change, because they fear the road of retrogression. The perfected responsibility system, guided according to the circumstances, is precisely what the peasants desire. Stability will not be difficult and perfection is attainable.

Do all the different forms of responsibility system have to be further perfected? The answer is yes. Because of their adaptabilities and limitations and their good points and defects, all the different forms of responsibility system need to be improved by means of summarizing the experiences. Only by following the method of dividing one into two and adhering to the doctrine of two aspects in everything will we avoid making the mistakes of subjectivity, one-sidedness and superficiality, bringing our old way of looking at things to the work of perfecting the responsibility system, and even believing that perfecting the responsibility system is to replace all its different forms with a certain form and seeking arbitrary uniformity. We must know that the various forms of responsibility system are not mutually exclusive. In the course of perfecting it, we must compare and make reference to the various forms, in order to learn the good points of others to offset our own weaknesses, incorporate things of diverse natures and bring out the best in all.

Why is the work of perfecting the responsibility system protracted? Because the emergence of the various forms of responsibility system in China's broad rural villages has produced a series of profound changes in the rural production relations and many complex problems calling for solution. A process is required for the broad cadres and masses to adapt to the changes, for the discovery and solution of problems and for the improvement of the entire operation and management level. Therefore, the work of perfecting the responsibility system cannot be completed by a short-term rush effort. It must be handled as the central link and long-term task of rural work, with greater achievements as the goal.

II. Correctly Handle the Relations between "Unification" and "Dispersal"

The various kinds of contract responsibility system consist of both "unification" and "dispersal," and "contracting" is the integration of the two. Therefore, correctly handling the relations between "unification" and "dispersal" is the crucial part of perfecting the responsibility system. "Unification" means that all matters suitable for unified operation and management are placed under collective unified operation and management, including items, links and measures of production, farmland capital construction, and arrangements for families of soldiers killed in action, households enjoying the five guarantees, the production and living of those with financial difficulties, and cultural and educational, public health and public welfare undertakings. "Dispersal" means that production items and productive activities suitable for decentralized operation and the appropriate production means are dispersed among and contracted to groups, households and labor forces. Through all forms of contracting, "unification" and "dispersal" are integrated and the enthusiasm of the collective and the individual enhanced.

Due to the different concrete conditions of the various areas and the different forms of responsibility system, the requirements for "unification" and "dispersal" cannot be identical. We must follow the principle of suiting the measures to the area and unify and disperse accordingly. In handling the relations between "unification" and "dispersal," the word "suit" must be stressed. The peasants demand self-determination in operation. Under China's concrete conditions, self-determination by the peasants and operation with peasant households or small groups as the units are feasible within a considerably long period of time, and we should encourage and develop the peasants' enthusiasm. Nevertheless, in the more than 2 decades of agricultural collectivization, the peasants have experienced the superiority of unified operation and cooperative labor. This superiority must continue to be developed in the future. According to the conditions today, collective unified management and arrangement of land use, other natural resources and crop layouts, of the use of large farm machinery and water conservation facilities, of the completion of the state purchase quotas and assigned purchase tasks, of the handling and use of collective deductions and reserves, of the livelihood of families of soldiers killed in action, households enjoying the five guarantees and those with financial difficulties, and of the planning of necessary and feasible farmland capital construction are favorable to the development of production and the perfection of the responsibility system. Naturally, as to which undertakings should be placed under unified operation or which ones should come first, the units must suit the measures to their own conditions.

Land, the basic production means of agriculture, belongs to the collective and is under its unified arrangement. Regardless of the form of responsibility system adopted, land contracting must be as rational as possible. When the responsibility system was launched, the peasants, concerned about changes in policy, all hoped to contract for a piece of land. Some areas divided the contract land evenly per capita, and a number of problems emerged in the production process, but there is no cause for alarm. Some households with many members but few labor forces wish to contract for less land and get more assignments for other kinds of labor. Craftsmen with special skills wish to pursue their own specialized labor and ask to have less or no land contracted to them. Those who are skillful in farming and have many labor forces wish to contract for more land. Such demands for readjustment out of their own free will should be encouraged and adroitly guided, in order to promote diversification, develop commodity production and advance toward the specialization and socialization of production. To dispel the peasants' fear of "change" and stabilize the policy, an extremely cautious attitude should be taken in land readjustment. It is the reason for the proposal made by some areas that "readjustment is required, but there should be no major or arbitrary measures." With the development of the rural economy, the growing number of specialized labor divisions and the gradual shift of the labor force to realms beyond farming, the masses will voluntarily make demands for readjustments. The course of readjustment should be natural, not forced.

As the collectively owned water conservation facilities, large farm machinery, industries and equipment are the valuable assets accumulated through the diligence of the masses of many years and will produce an important effect in the development of production, they must be properly protected and utilized, and the damaged articles repaired for reuse. In regard to such collective assets under unified management and use, the articles suitable for contracting out for specialized use should be so handled, so that they can be fully utilized. All collective fixed assets must be recorded in books, and articles suitable for dispersed custody and use rationally priced, thereby safeguarding the principal and the value.

III. Properly Handle the Several Integrations

The agricultural production responsibility system has activated the entire rural work and enlivened the rural economy. If the tasks connected with the responsibility system are properly performed, it will surely promote its stabilization and perfection. Therefore, the following several integrations must be properly handled:

1. Integration of perfecting the responsibility system and developing rural difersification: After introducing the responsibility system in various forms, the rural labor force, due to the higher efficiency, generally has one-third surplus time with nothing to do. Actively deploying diversification, seeking outlets for the surplus labor force, changing the irrational situation in some areas where "the entire labor force is assigned to farming" and developing the commodity economy constitute a prominent issue calling for solution. Perfecting the responsibility system and deploying diversification are mutually complementary, mutually promotive and closely linked. The responsibility system has enhanced the productive enthusiasm and creativity of the masses, improved labor efficiency, attained the goal of higher output and higher income and provided labor and capital for diversification. Deploying diversification will expand the fields of production and create the premise for solving the problem of surplus labor force, promoting specialized labor division and building a sound responsibility system. In line with the practical conditions of the natural and labor resources of their own units, the communes and brigades following the various forms of responsibility system must utilize the economic strengths already accumulated, launch the masses, open all avenues to create wealth, gradually add new items of production, organize all kinds of special teams, groups, households and labor, practice the responsibility system of specialized contracting and compensation linked with output, and raise labor productivity and products commodity rate.

2. Integration of the production and technical responsibility systems: The agricultural production responsibility system has led to the "science craze." With an unprecedented enthusiasm for science, the broad peasants urgently demand new productive technology to increase production. To adapt to the new situation and satisfy the demand of the broad peasants, the agricultural technical popularization units and scientific and

technical personnel (including peasant technicians) must establish a technical popularization responsibility system between the collective production units and the contractors, so as to furnish reliable scientific and technical guidance and guarantee to production. The technical responsibility system may be a combination of many items or cover only a single item; it may follow the method of compensation linked with output or collect only the cost or service charge. The forms of the technical responsibility system may be manifold and adjusted to the local conditions, but the principle of free will must be upheld, with benefit for both sides. When forming a technical contract, the rights, responsibilities and benefits of both sides and the concrete method of performance must be stated clearly, in order to facilitate inspection, implementation and fulfillment.

3. Integration of perfecting the responsibility system and reorganizing financial affairs: Reorganizing financial affairs is a crucial link in perfecting the responsibility system. With the introduction of the responsibility system in various forms, financial management must be adapted to this development and change. When the accounts are in confusion and the commune members have no trust in the collective and the cadres, building a stable responsibility system is out of the question. Therefore, reorganizing financial affairs and perfecting the responsibility system are directly linked and constitute the two sides of one issue. In reorganizing financial affairs, the old accounts must be settled and made known to the commune members and the relations between credit and liabilities clarified. Collective goods and materials and assets must be inventoried, verified and recorded, new accounts established and a stringent financial management system set up. A crucial task indispensable for building and perfecting the responsibility system, it must be properly handled.

IV. Properly Form, Manage and Fulfill Contracts

The responsibility system in its various forms cannot be separated from the word "contract." Forming contracts, concretely integrating "unification" and "dispersal," and fixing the rights, duties and interests of the collective and the contractors constitute a crucial aspect in perfecting the responsibility system and the principal means to give first place to the planned economy, with consideration for the interests of the state, the collective and the individual, and to ensure the implementation of the responsibility system. There can be no responsibility system without contracting. Therefore, all units following the responsibility system should also practice the contracting system.

As the forms and the patterns of operation of the various kinds of responsibility system are not identical, the contents of the contracts should also differ. Generally speaking, the production teams must specify the kinds, amounts and quality of production means and the time and technical service to be furnished to the contracting units. The production teams with a fairly high unified operation must also specify the production expenses, the items of unified operation and the labor compensation to be furnished by them. As a rule, the contracting side must specify the varieties contracted for, the amount or value (profit) of the products to be completed, and the material objects and cash to be turned over to the higher level. The units practicing contracting by households must severally specify the man-days for the required and assigned purchase tasks of the state and for agricultural capital construction, civil construction and public welfare undertakings. The inclusion of birth control in the contracts in many areas is a good means to control population growth.

When introducing the contract system, the forming of the contract must first be properly handled. As the process of forming a contract is the process of educating and launching the masses, the formalist practice whereby "the cadres set the quotas and the masses affix their seals" must be avoided by all means. Only the quotas decided after conscientious discussions and by agreement of both sides will have the guarantee of fulfillment. After a contract is signed, close attention must be given to supervision and inspection and problems must be uncovered and solved promptly. There must be no delay until the last minute to make a final accounting, wasting time and bungling matters. To ensure the fulfillment of a contract, the production team must first conscientiously perform its obligations specified in the contract before it can demand performance by the contractor. The contract must not be regarded as a notification to the commune members of the tasks to be performed by them. The most important point is that the utilization of the contracting system must be mastered, in order to organize production and manage the economy more efficiently, enable the collective economy to develop rapidly under unified planning and organically integrate the interests of the state, the collective and the individual.

V. Strengthen the Basic Level Leading Groups

Properly building the basic level leading groups, especially those of the production teams, is the key to perfecting and stabilizing the responsibility system. The introduction of the various forms of responsibility system is not only a readjustment of the rural production relations, but also a series of changes involving the superstructure. The duties of the basic level rural cadres and the political and economic functions of the basic level organizations must be adapted to the changes.

According to the experiences of the various areas in reorganizing and building the basic level leading groups, generally the following three tasks must be properly performed:

1. We must educate the cadres by all kinds of ways to improve their understanding. That some cadres fail to comprehend this major readjustment of the rural production relations and keep pace with it in their ideology is understandable. We should clearly announce to them: Regardless of what production responsibility system is followed, the burden of the

basic level cadres is not reduced, but increased, and the view that, "by contracting to the households, the cadres are no longer necessary" is incompatible with the facts and incorrect. We must reinforce the ideological-political education of the basic level cadres, commend the advanced, build their sense of honor and responsibility as cadres and, by means of the necessary democratic procedure, make them step forward justly and boldly to perform the work.

2. We must clarify the spheres of duty of the basic level cadres under the new situation, build and perfect their personal responsibility system and rationally solve the problem of their compensation.

3. We must conscientiously and properly perform the work of cadre training. It is a crucial link in perfecting the responsibility system. Many basic level cadres lament: "The old methods don't work, and we don't know the new methods." We must, by way of training, enable them to learn the new methods, improve their operation and management level and adapt to the need of the new situation as rapidly as possible. Under the new situation where most production teams follow the practice of contracting with the households, we must teach the cadres to render classified guidance of the contracting households. The households with a strong labor force, skills and capital must be induced to get rich by labor and refrain from dishonest practices; those with a weak labor force and inadequate capital must be concretely helped to overcome their difficulties and develop production.

After undergoing the party's long education, the overwhelming majority of our basic level cadres is fairly good. As long as the above-mentioned problems are solved, they will be willing to perform the work properly. The leaders of the various levels must actively support the cadres in their work, help them learn the work methods under the new situation, improve the leadership style and enable the cadres to do their work more efficiently.

We must fully understand the crucial importance of perfecting and developing the agricultural production responsibility system, resolve to wage a protracted struggle for it, promptly uncover and solve the new problems, summarize the new experiences and strengthen the responsibility system.

RURAL SAVINGS, LOAN SITUATION REPORTED

Increased Rural Savings

Beijing ZHONGGUO NONGMIN BAO in Chinese 14 Oct 82 p 1

[Text] Chinese Bank of Agriculture director, Han Lei [7281 7191], said recently at a conference to exchange experiences on improving the economic effectiveness of farm loans that both rural bank savings and loans are flourishing in China today, and economic effectiveness of rural credit is gradually improving.

Statistics show that as of the end of August this year, rural savings totaled 48.9 billion yuan for the country as a whole, an increase more than double that of the same period in 1978. This includes commune members savings accounts totaling 25.14 billion yuan. Bank and credit cooperative rural loans outstanding of various kinds total 66.94 billion yuan, 26.43 billion more than during the same period in 1978. This includes loans to double-contracting households [households contracting to meet fixed output quotas and contracting full responsibility for task completion], specialized households and key households as well as loans to rural market town industries and business and service trades, all of which have increased considerably. During the past several years, the increase in rural savings has been greater than the increase in rural loans. At the same time, as a result of the improved economic effectiveness of loans, the turnover period for loan funds has accelerated. Between January and August this year, loans issued amounted to a cumulative 181.47 billion yuan, and the amount repaid amounted to 179.53 billion yuan, or 98.9 percent of the cummulative amount of loans issued. This conference, which China's Bank of Agriculture convened in Shijiazhuang during the latter part of September, exchanged and summarized experiences and accomplishments in rural banking work since the Third Plenary Session of the 11th Party Central Committee. This was also a conference for the rural banking system's implementation of the spirit of the 12th Party Central Committee and for mobilizing further support for the development of agriculture.

Effective Use of Rural Credit Explained

Beijing ZHONGGUO NONGMIN BAO in Chinese 14 Oct 82 p 1

[Text] Ever since the Third Plenary Session [of the 11th Party Central Committee], rural banking work has developed greatly. Rural savings have increased rapidly, and the economic effectiveness of rural loans has steadily increased.

What does economic effectiveness of rural loans mean? It means commune brigade and commune member use of bank loans to lower costs, to raise output, and to increase earnings, repaying the loan funds on time. In order to accomplish this, units using the funds must strengthen their economic accounting, calculate carefully, and make full and effective use of funds.

Some people ask whether in order to raise economic effectiveness farm loans are also used to support "poor brigades and production teams." Actually there is no contradiction between raising economic effectiveness and supporting poor brigades and production teams. Formerly banks supported quite a few brigades and production teams and the main reason why some funds were never repaid was poor economic effectiveness. If rural banks are to increase economic effectiveness, they cannot use loans for relief, respond to every request and make loans blindly as they did in the past. They have to look into actual circumstances, investigate and study, help and support poor brigades and production teams adapt general methods to local situations, make the most of advantages, open avenues for production, undertake production activities that require little investment of funds, that produce quick results, and that bring large benefits, use genuinely workable measures to increase output and earnings, develop a commodity economy, and increase income. The credit principle of selecting the best for support means selection of those best in economic results rather than selection of the poorest or the richest. Whoever holds superior prospects gets support. In a certain sense, poor brigades and production teams offer the greater potential for development of production, and frequently they are more superior.

People also ask why there is so much emphasis on repayment of loans on time in raising the economic effectiveness of farm loans. Farm loans are rural savings that the Bank of Agriculture and credit cooperatives have taken in. Savings are paid in and paid out, so credit funds must be loaned out and repaid. Only when banks and credit cooperatives are repaid on time can they continue to issue loans, to accelerate the circulation of funds, and make a single penny do the work of several to satisfy more needs in the building of production. Therefore, the Bank of Agriculture and credit cooperatives have to strengthen credit management and set time limits on credit in accordance with credit policies and the cycle for building agricultural production, issuing and collecting loans on time. Units that borrow funds should also bear in mind the overall situation, strictly abide by credit agreements, and take the initiative in returning funds on time in order to assure turnover of funds and raise the economic effectiveness of credit funds.

SPUR GIVEN TO LAGGING COMMUNE FINANCIAL REORGANIZATION WORK

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] No 10, 6 Oct 82 pp 2-3

[Article: "Continue to Take Firmly in Hand and Do a Good Job of Financial Reorganization This Winter and Next Spring"]

[Text] According to statistics as of the end of June this year, 35.5 percent of the nation's production teams had instituted reorganization of rural commune and production brigade finances as part of a nationwide effort, and 30.3 percent of production teams had finished this task. In all places in which a fairly good job of financial reorganization has been done, benefits have been quite remarkable. They have been exhibited in the following ways: (1) Clarification of property owned by the collective economy in preliminary solution to a problem of several years standing of discrepancies between records and realities. (2) Checking up on losses and waste and the evil practices of entertaining guests and sending gifts for influence purposes, with promotion of financial management systems of responsibility of fixed norms for expenditures and assumption of sole responsibility for finances, which have promoted increased income and economizing on spending. (3) Clarification of credits and liabilities, with the recovery of some funds owing and funds overspent by commune members. (4) Disposition of a group of cases involving corruption and embezzlement, with recovery of property belonging to the collective, redemption of a group of cadres, and improvement of relations between cadres and the masses. These actions have been extremely beneficial in maintaining public ownership of the means of production, and in buttressing confidence, about running the collective economy well. (5) Establishment and perfection of fiscal accounting systems, training and testing of rural accountants, and elevation of the professional level of financial accounting personnel.

Problems currently existing in commune and brigade financial reorganization are the following: (1) Progress has been very uneven. Some municipalities and counties have already completed this work, while numerous other municipalities and counties have not yet begun it. (2) Some of the communes and brigades that have completed reorganization have not complied with requirements of State Council Document Number 10, and make-up work has to be done. (3) A large number of the economic problems uncovered have yet to be taken care of. (4) The basic professional knowledge of still another portion of accountants is very poor. In some production teams old accounts have not been reconciled and new accounts have not been entered on time or according to regulations, resulting in missing recores or mistaken records etc. There are numerous reasons for the foregoing such as "insufficient attention on the part of leaders, or caring only about getting on with the job without concern for quality, and neglecting consolidation of the results of reorganization, plus too frequent changes in production team accountants, new accountants having poor basic skills, etc.

The CPC Central Committee and the State Council have issued repeated injunctions requiring decisive reorganization of commune and brigade finances. We must zero in on existing problems and take a firm grip on this work this winter and next spring for fundamental solution to this deadly problem of bad financial management. Those communes and brigades that have yet to begin financial reorganization should devote a block of time to it and organize specialized teams to act in accordance with CPC Central Committee and State Council requirements. They should run pilot projects and then rapidly expand to reorganize a large number this winter and next spring, striving to complete commune and brigade financial reorganization by the end of next year. Places that advance in their reorganization work fairly rapidly should turn attention to the handling of economic problems, and devote attention to the task of inspecting and examining before accepting results so as to assure quality or reorganization. Communes and brigades that have done sub-standard reorganization work are to conduct new surveys and make up deficiencies, augmenting wherever necessary to meet requirements of State Council Document Number 10, maintaining quantity and quality in fulfillment of financial reorganization tasks.

Training of financial accounting personnel should be intensified. Profiting from the lessons of experience about technical problems that come to light in accounting, strengthening of training in basic skills, and stabilization of the accounting corps are extremely important. Only when attention is devoted to basic tasks can ledgers, statistical forms, and vouchers be standardized and normalized, ahd further disorder be prevented following this reorganization. The reorganization should be constructive in nature, improvements being sought through the reorganization.

In order to consolidate the fruits of the reorganization, communes and brigades will have to be helped manage money matters democratically. A money management committee consisting mostly of commune member representatives and attended by commune and brigade cadres and financial accounting presonnel should be established. Democratic money management campaigns should be regularly carried out. Various ledgers central maintained by the collective, as well as withholdings from operations by individual households should be publicly posted or announced orally so that financial work will be under the scrutiny of the masses.

Regardless of the pace of financial reorganization, leadership should be strengthened, attantion devoted to the training of accounting personnel, inspection and examination prior to accptance firmly grasped, and consolidation and upgrading attended to.

State Council Document No 10 pointed out that "People's governments at all levels must conscientiously reorganize commune and brigade finances, halt losses, waste, and corruption, and improve economic effectiveness as a matter of importance in present rural work that is to be placed on their daily agendas and linked to perfection of production responsibility systems. They are to launch economic diversification and other kinds of rural work and, under the centralized leadership and centralized deployment of CPC committees at all levels, they are to conscientiously and unflaggingly continue to do a solid job in order to achieve anticipated results." We are determined to reorganize finances in accordance with this demand to make a contribution to steady improvement in commune and brigade economic effectiveness.

CONTROL OF YELLOW DWARF DISEASE OF WHEAT DISCUSSED

Beijing NONGCUN KEXUE [RURAL SCIENCE] in Chinese No 8, Sep 82 p 18

[Article by Qian Youning [6929 1635 1380]: "Yellow Dwarf Disease of Wheat"]

[Text] Yellow dwarf disease is the major wheat disease in China.

It occurs in all provinces. This disease damages mostly wheat, barley, naked oats, and broom corn millet, and it can cause serious damage to wheat. In 1970, for example, as a result of yellow dwarf disease, the provinces of Shaanxi, Gansu, and Ningxia had a reduction in output of about 1 billion jin. Wheat dwarf disease virus granules are spherical polyhedrons with a diameter of 26 millimicrons (a millimicron being one one-billionth of a meter), and they can be spread only by aphids. In China maiercha aphids [7796 0059 0643 5742], wheat aphids [macrosiphum avenae (Fabricus)], yiguan aphids [4898 4619 5742], and wuwang cangguan aphids [3541 4853 7022 4619 5742], can spread them. The most powerful carrier is wheat aphids [macrosiphum avenae]. When the piercing and sucking mouth of wheat aphids penetrates the leaves and stems of diseased plants to suck out the juices, it takes only 30 minutes of sucking for wheat aphids to contract the virus. A wheat aphid carrying wheat dwarf disease can then transmit the virus to uninfected wheat by feeding on it for from 5 to 10 minutes. Happily the viruses cannot reproduce within the aphids' bodies, nor can the aphids pass the virus along to succeeding generations. Only by feeding on diseased plants themselves can newly born aphids contract the virus. This eases the problem of controlling this disease.

Once wheat contracts yellow dwarf disease, the tips of the leaves begin to turn yellow first. The yellowing follows the veins in the leaves, producing alternating yellow and green stripes on the leaves and gradually progressing to one-third to one-half of the leaf surface. The leaves become thick, hard, stiff, and upright. If the disease is contracted during the seedling stage, in serious cases the seedlings die during the period of greening up the following year. If the infection is light, the seedlings do not die, but the disease continues to develop in new leaves; tillering is reduced; serious dwarfing occurs; and there is either no spiking or else spikes are very small. If the disease is contracted during greening up or during the jointing stage, the leaves of infected plants gradually turn yellow from bottom to top. During the booting stage, from one-third to one-half of the surface of boot leaves of infected plants turn bright yellow, and the other leaves gradually turn yellow from top to bottom. Spikes depend mostly on leaves for nourishment, and boot leaves are the principal source of nutrients for spikes. So after the leaves turn yellow, the effect on yields is very great. Though plants infected during the late stage of their growth are able to form spikes, grains are blighted. Whether or not leaves of wheat plants infected with dwarf disease turn yellow has a lot to do with temperatures. When temperatures are between 15 and 20 degrees centigrade, incidence of disease is apparent, but when temperatures are above 25 degrees centigrade, there is no outbreak of the disease even though the wheat plants carry the virus. This is called latent infection. Once temperatures drop to between 15 and 20 degrees centigrade, the disease can break out.

Inasmuch as yellow dwarf disease if wheat is transmitted by aphids, the spread and degree of seriousness of this disease is closely related to the migration of aphids. When the wheat ripens and is harvested, the aphids that transmit the wheat yellow dwarf virus can no longer find sufficient nourishment, and large numbers of winged aphids then fly to their summer hosts, which are corn, gaoliang, broom corn millet, millet, paddy rice, wild-growing wheat, and numerous other plants of the grass family. However, these hosts are not necessarily hosts for the wheat dwarf virus. Only certain varieties of corn, wild wheat seedlings and grasses such as broom grass, oats, dalingfeng grass [1129 0407 7364 5430], huamei grass [3973 4168 5430], and huwei grass [5706 1442 5430] are hosts for yellow dwarf virus. When the winter wheat sown in autumn sprouts, the virus infected wheat aphids fly back from their summer hosts, spreading the virus to the wheat again so that it continues to spread.

Numbers of wheat aphids are related to temperature and humidity. Generally when October average temperatures are high and there is little rainfall, and when average temperatures during the following January and February are high with no "return to cold in spring" during March and April, conditions favor outbreaks of wheat aphids. Practice has shown that in years of serious infestations of wheat aphids [macrosiphum avenae], incidence of yellow dward disease is also great.

Control of wheat yellow dwarf disease depends mostly on prevention and all-around control. First is breeding of disease tolerant superior varieties. None of the wheat varieties currently in use has been found to be immune; they are only relatively disease resistant or disease tolerant. In general, most local peasant varieties are fairly resistant or tolerant of the disease. Second is control of aphids to prevent disease. This is currently the principal method used to control yellow dwarf disease. For early sown wheatfields in winter wheat growing areas, 3911 [phorate] may be mixed into the seeds, between 0.2 and 0.3 jin of 75 percent 3911 being used per 100 jin of wheat seeds. Between 6 and 8 jin of water should be added and stirred evenly. After mixing, the seeds should be piled and covered for 12 hours. This pesticide remains effective for about 35 days. 3911 is an intensely poisonous pesticide, so the safety of people and animals should be watched when it is used. In years when yellow dwarf disease is at normal levels, after mixing the seeds, there is no need to control aphids before the onset of winter. However, if temperatures are fairly high, the weather dry, and the incidence of wheat aphids more than between 10 and 15 per 100 wheat plan plants, spraying should be done once. Between the time when the wheat greens up and the jointing stage, control of aphids should be done once or twice more to control the spread of wheat yellow dwarf disease. Depending on the aphid situation in spring wheat growing areas, benefits frmm spraying of insecticides in early to mid May are fairly good. Insecticides that may be used include the following: a 1000 - 1500 part solution of dimethoate emulsion, a 200 - 300 part solution of 50 percent 1605 [parathion] emulsion, or alternatively 1 percent 1605 powder or 1.5 percent dimethoate powder, spraying 3 jin per mu. In addition, seeds should be sown at the right time, winter watering done, the ground compacted before the onset of winter, the ground harrowed after greening up has taken place, and tending with nightsoil intensified. All these things help reduce damage caused by yellow dwarf disease.

ANHUI

WAYS TO LOWER FARMING COSTS ILLUSTRATED

Beijing GONGSHE CAIWU [COMMUNE FINANCIAL AFFAIRS] in Chinese No 10, 6 Oct 82 pp 28-30

[Article by Zhang Chuanquan [1728 0278 2938]: "Potential Still Great For Lowering Production Expenses--A Survey of Xiaowu Production Team's Production Expenses"]

> [Text] Editor's Note: The survey of Xiaowu Production Team's production expenses is representative, and merits the attention of all. After this production team instituted agricultural production systems of responsibility, production developed, income increased, and benefits from investment markedly improved. However, potential for increased output and savings is still great. All that is needed is a strengthening of leadership, good organization to pass on technical skills, help to commune members to take good care of their plow oxen and water conservancy, and good organization of the supply of means of production for use in agriculture, and it will be possible to lower production expenditures stil further and greatly increase results from investment.

Xiaowu Production Team in Fangqing Production Brigade, Liupu Commune, in Dingyuan County, Anhui Province has 139 people in 26 households and 480 mu of cultivated land. The land is fairly fertile, and water conservancy conditions are rather good.

Comparison of 1981 with 1977 shows grain output totaling 258,000 jin, up 40.6 percent; oil-bearing crop output totaling 28,300 jin, up 5.9 fold; ginned cotton output totaling 1,800 jin, down 29 percent; gross earnings from agriculture amounting to 53,000 yuan, up 118.7 percent; and production expenses of 8,520, up 76 percent. Production expenses as a proportion of gross income fell from 20 percent in 1977 to 16.1 percent. For each yuan of investment an output value of 6.20 yuan was created, a 24 percent increase. Production expenses were 17.8 yuan per mu, up 77 percent. Output value was 110.40 yuan per mu, up 118.6 percent.

These figures show that since this production team instituted production responsibility systems, agricultural income has increased, production expenses have decreased, economic effectiveness has risen, and results have been outstanding. However, a look at the survey shows that the rise in this production team's economic effectiveness is still along way from peaking, and potential for both increases in output and savings is still very great.

1. Careless and reckless use of chemical fertilizers. In 1981 this production team used 28,400 jin of chemical fertilizer, 3.03 times the amount used in 1977, the average amount used rising from 19.5 jin per mu to 59 jin per mu. Some commune members figures on "making a fat man with one bite" and applied too much chemical fertilizer, with the result that crops remained in the vegetative growth stage, ripened late, lodged, and produced decreased yields. Some other commune members gave no thought to the soil's need for nitrogen, phosphate or potash, simply scattering fertilizer on the fields when they had it, with the result that much money was spent for no increase in yields.

2. Commune members rarely bought chemical fertilizer at parity price; they had to buy it at negotiated prices. High-priced fertilizer increased production expenses additionally. Take the case of just phosphate fertilizer as an example. Last year this production team used 9,700 jin of phosphate fertilizer, of which only 700 jin was bought at parity price at a per unit cost of 0.066 yuan. It bought 4,000 jin at negotiated prices at a per unit cost of 0.092 yuan. Yet another 5,000 jin was bought from private individuals at the high per unit price of 0.10 yuan. Last year this production team used a total of 28,360 jin of chemical fertilizer, of which only 3,800 jin, or 13.4 percent was bought at the parity price, the remainder being purchased at negotiated prices or high prices. Had all the fertilizer been purchased at parity price, a saving of 459.60 yuan would have been realized from this action alone, the decrease in expenses averaging 0.96 yuan per mu.

3. Seed waste, Seeds were soaked without rhyme or reason, particularly for paddy rice. Some people one-sidedly stressed "buy seeds if money is available; buy seedlings when money is not available," excessively increasing the amount of seeds that were soaked. Last year this production team planted 230 mu of paddy for which it used 9,240 jin of seeds, or an average of 40 jin per mu. The first batch of seedlings that commune member Wang Benfu [3076 2609 0102] grew was more than enough, but he was still concerned, so he soaked another 120 jin of rice to grow more seedlings, not a single plant of which was used, the entire amount being wasted.

This shows that potential for increasing economic effectiveness and lowering production expenses is still very great. Of course, in order to lower production expenses, first it is necessary to try to increase output; absolutely no saving of necessary expenses can be made without impairing increases in yields. What is needed is to avoid or reduce any further waste of production expenses. The situation in Xiaowu Production Team shows a need to solve the following several problems:

1. Raise the technical levels of all commune members. The technical quality of commune members has a very great bearing on growth of production and improvement of economic effectiveness. Grassroots party organizations and scientific and technical departments should vigorously publicize and popularize scientific agricultural knowledge; they should organize agricultural technical guidance teams to go into frontier and mountain regions to publicize and give guidance. When selling chemical fertilizers or pesticides, supply and marketing departments should explain to the masses, or print and distribute instructions on the characteristics and methods of using goods such as chemical fertilizer so that the masses can adapt general methods to specific circumstances to apply the right amount skilfully. In addition, greater use of barnyard manure and green manure should be vigorously advocated to improve the soil and increase its fertility to get large results while saving on expenses.

2. Strict water use system with drawing up of water use agreements. A comrade who is devoted to duty and conscientious about responsibilities should be selected to be in charge of water, and a water management responsibility system should be established. Those who do a good job of water management should be appropriately rewarded, and thos who do a bad job should have their remuneration reduced. Commune members should be indoctrinated in mutual help, friendship, and solidarity in the use of water.

3. Encouragement to commune members to form associations of households to riase oxen and use oxen to reduce the watse of draft animal power. Before this production team instituted responsibility systems, it had 11 oxen seven of which satisfied needs for draft animals. Now the number has grown to 20, of which 14 are used. Commune members Jiang Jiarong [5592 1867 2837] and Wu Liding [0702 4539 7307] each have a family of eight and 30 mu of land on which each family uses one large male ox, when an ox can really plow about 70 mu of land. In both families the oxen work half the time and are idle half the time. Figured on the basis of an annual 80 to 100 yuan depreciation per ox per year at prevailing prices for oxen, this means a very great increase in expenses, and it is also a very great waste. Nowadays three or four fellows also use a single ox. Practice has shown that when responsibilities are clear, matters can be managed well. Commune members should form associations of households on the basis of land area to be famred to raise and use oxen, so that everything is used to the full and unnecessary waste is reduced.

4. Agreements should cover the chemical fertilizer that the state supplies peasants, and these agreements should be honored. When violations of agreements occur, the reasons should be found and economic responsibility assigned. It is forbidden to make chemical fertilizer into "cadre fertilizer," or "backdoor fertilizer." The peasants' interests may not be damaged.

SUCCESS REPORTED IN RURAL ECONOMIC DIVERSIFICATION

Lanzhou GANSU RIBAO in Chinese 7 Sep 82 p 2

[Article: "Great Development of Economic Diversification"]

[Text] In the process of carrying out a program of "positively no relaxation of grain production while actively developing economic diversification" in the wake of the Third Plenary Session of the 11th Party Central Committee, all jurisdictions in Gansu Province have made the most of strengths while avoiding weaknesses, and have made the most of individual advantages, thereby effecting changes in the internal structure of agriculture. Following institution of production responsibility systems largely of the kind in which there is large scale assigament of responsibilities, in particular, both collectives and individuals have moved ahead, attention has been devoted to matters both large and small, and a new situation of great development of economic diversification has taken place.

Statistics provided by departments concerned show that despite natural disasters to agriculture during 1981, including drought and waterlogging which reduced grain and oil-bearing crop outputs, output value of economic diversification increased by 15 percent over 1980, reaching 104 million yuan. Not only did it make up for losses sustained as a result of decline in grain and oil-bearing crop outputs, but it also resulted in a net increase in gross output value of agriculture for the province as a whole of 11.65 million yuan. Output value of economic diversification as a ratio of gross output value of agriculture rose from 37.3 percent in 1978 to about 45 percent. A survey of earnings of 420 commune member households showed that in Gansu Province commune member family net earnings from household sideline occupations averaged 52.44 yuan, a more than twofold increase over 1978.

An economic diversification developed, commune member cash income increased. Rural savings accounts in 1981 were 170 percent larger than in 1980, and volume of country fair market transcations increased by 28 percent over 1980. For the first half of this year volume grew another 20 percent over the same period last year.

During the first half of this year, new growth took place in economic diversification throughout the province. For commune and brigade enterprises alone, earnings for the first half of the year reached 131.87 million yuan, 38.9 percent more than for the same period last year.

Results of Diversification of Farming

Gansu covers a vast area, has a complex topography, and climatic variations are great, suiting it to the growing of all kinds of cash crops. During the past 3 years, with the liberation of rural economic policies all jurisdictions have reversed the trend toward a single grain crop economy to place both economic diversification and the growing of grain crops in an important position. They have surveyed resources, formulated plans, and vigorously developed farming. A considerable number of communes and brigades have formed, or are in process of forming, commodity production bases for cotton, oil-bearing crops, sugarbeets, balck wood fungus, tea, raw lacquer, almonds, roses, lilies, daylilies, black and while watermelon seeds, silkworm mulberry, sunflowers, and medicinal herbs. Fairly rapid development has taken place in the growing of cotton, oil-bearing crops, sugarbeets, sunflowers, wood fungus, raw lacquer, tea, medicinal herbs and tobacco. Production of local specialties such as walnuts, daylilies, red dates, roses, almonds, and black and white watermelon seeds has also revived and developed.

Data from statistical departments shows the following:

Item	1981 Gross Output (Million Jin)	1978 Gross Output (Million Jin)	Proportional Increase (%)
Cotton	7.98	6.74	18%
Oil-bearing Crops	190.87	155.81	23%
Sugarbeets	212.32	116.25	83%
Sunflower Seeds	544.6	161.5	2.3 fold
Black Wood Fungus	.110,990	830.39	34%
Raw Lacquer	.155,992	735.86	1.1 fold
Tea	.104,491	450.26	1.3 fold
Medicinal Herbs	30.28	22.59	34%
Tobacco	15.7	9.65	63%
Vegetables	546.24	493.94	11%

New Advances by Commune and Brigade Enterprises

During the past 3 years the province's commune and brigade enterprises have carried out a program of readjustment. Readjustments and conversion of production has been done in enterprises for which raw materials cannot be assured, whoes products do not sell, and whose technology does not pass muster. Following readjustment, 15,105 existing commune and brigade enterprises in the province have strengthened management, and 90 percent of enterprises have established systems of responsibility whereby calculation of compensation is linked to production, solving the problem of eating out of a large common pot. This year a new situation of great development of commune and brigade enterprises has occured.

Statistics from the Provincial Commune and Brigade Enterprises Administration show that in 1981 gross income for the province's commune and brigade enterprises amounted to 327.86 million yuan. This was 17.3 percent of income in the three-tier rural economy, and a 1.55 percent of income over 1978. It averaged 19.87 yuan per capita of rural population. In Lanzhou, where commune and brigade enterprises have grown fairly rapidly, in 1981 gross output value was 96.31 million, 33 percent more than in 1978. Gross income was 38 percent of gross income from the city's agriculture, 9 percent more than in 1978. Income averaged 40 yuan per capita of rural population. Revenues paid during a 3 year period amounted to 8.79 million yuan, 3.3 times the state investment in commune and brigade enterprises. During the first half of this year, throughout the province commune and brigade earnings increased month by month, income increasing 38.9 percent over the same period last year. Lanzhou City has had earnings of 51.21 million yuan, up 62.9 percent from the same period last yearfor 50.2 percent fulfillment of this year's plan. The city has fulfilled more than half its quota in more than half the alloted time. Practice has shown that commune and brigade enterprises have developed into a strong pillar of the rural economy. Their development supplements shortages in state plans, augments market needs, and supports the building of cities.

High Benefits From Concentrated Investment

The province's new situation of great development of economic diversification could not have taken place without the energetic support that the state has provided.

Statistics from provincial financial departments show that during the past 3 years state and local treasuries have invested a total of more than 48 million yuan in development of economically diversified production. This investment has been made through the supply and marketing, agriculture, animal husbandry, forestry, and commune and brigade enterprise system, and has been concentrated in each area in a planned way with certain objectives in mind for the building of economically diversified commodity bases. This has been a change from the past method of "scattering shots" without regard for benefits to be derived from investment. Initial results have been received from construction in more than 20 counties, with the direct support of the supply and marketing system, of commodity bases for black wood fungus, day lilies, melons and fruits, black and white watermelon seeds, citrus fruits, and bailan melons [4101 5695 3900].

The animal husbandry system has supported the building of 371 superior breed ox frozen semen sites, and has purchased 25 frozen semen liquid nitrogen transportation vehicles for the sites. During the first half of this year alone, these sites have helped in the breeding of more than 26,000 oxen. The same system supported more than 220,000 hardship households in the raising of more than 300,000 sheep, 130,000 chickens, and more than 44,000 head of large livestock animals of various kinds.

Over a 2 year period, the forestry system supported communes and brigades in the afforestation of 1.08 million mu, in the growing of 97,900 saplings, and in the growing of 50,000 mu of firewood forests.

The Commune and Brigade Enterprises Administration concentrated investment on preparations for construction of a monosodium glutamate plant in Tongwei County, a furfural plant in Shuangshu Commune, Wuwei County, a paper manufacturing plant in Sanjiaocheng Commune in Yuazhong, and mixed livestock feed plants in Quanhu Commune in Jiuquan County, and in Dongba and Zhongdong communes in Jinta County. A cold storage plant has been built and has begun operating a Shanhe Commune in Zhengning County with marked economic benefit. Last July, following operation of the Shanhe Commune cold storage plant, 25 tons of rabbit meat were stored in it during the same year, and commune members earned more than 200,000 yuan from sales of rabbits. Thus local "difficulties in selling rabbits" were solved, which the peasants very much appreciated.

WHEAT, COTTON YIELDS, COMMODITY RATES INCREASE

Beijing ZHONGGUO NONGMIN BAO in Chinese 14 Oct 82 p 1

[Article: "Changed Situation in Henan's Low and Medium Yield Areas; Continuous Increases in Wheat and Cotton Yields and Rapid Increase in Commodity Rates"]

[Text] Serious attention on the part of the Henan Provincial CPC Committee and provincial government to the medium and low yield areas that make up two-thirds of the province has advanced all-around balanced increases in output, and commodity rates have also risen very rapidly.

There are 72 counties in Henan Province that have grain yields of less than 600 jin per mu and where average per capita earnings are less than 100 yuan. These medium and low yield areas have small populations relative to available land, and potential for increased yields is very great. In 1978, the Henan Provincial CPC Committee and the provincial government made a series of decisions for hastening change in medium and low yield areas that spurred these areas to remarkable changes within the short period of 3 years.

In the four prefectures of Nanyang, Zhoukou, Zhumadian, and Xinyang, this year's summer grain output reached 11.4 billion jin for an annual increase during the past 3 years averaging 1.48 billion jin. Wheat output in these four prefectures as a ratio of total summer grain output for the province as a whole rose from 31 percent in 1978 to 48 percent this year. Medium and low yield area cotton production also developed very rapidly. In 1980, in Zhoukou and Kaifeng prefectures, cotton yields broke the 100 jin per mu mark. The province has a cotton growing area of 100,000 mu, and of the province's 31 counties with yields of more than 100 jin per mu, formerly 22 had yields of only 30 to 50 jin per mu. Fugou County in Huangfan Prefecture formerly had a single crop economy and commune members' lives were hard. During the past 3 years grain and cotton have developed simultaneously, and last year cotton yields averaged 132 jin per mu on 293,000 mu, while grain output increased by 20 million jin over 1978.

Bumper agricultural harvests have sparked development of forestry, livestock raising, and sideline occupations, and has increased economic income. Last year distributions from the collective to commune members in the county increased from an average 62 yuan per capita in 1978 to 176 yuan.

Following the increase in output from medium and low yield areas, commodity rates also rose rapidly. This year six counties turned over more than 100 million jin of wheat to the state, 26 counties turned over more than 50 million jin; 21 communes turned over more than 10 million jin; 40 production brigades turned over more than 1 million jin; and there were 220 peasant households that turned over more than 10,000 jin, an overwhelming majority in the former medium and low yield areas.

WHEAT PLANTING SUBSTANTIALLY COMPLETED IN YAN'AN PREFECTURE

Xian SHAANXI RIBAO in Chinese 19 Sep 82 p 1

[Article: "Nearly 1 Million Mu of Wheat Planted in Yan'an Prefecture. Spirit of 12th Party Central Committee Spurs Peasants To Do a Good Job of Autumn Sowing"]

[Text] The call issued by the 12th Party Central Committee for an all-around socialist economic upsurge has spurred the peasant masses in Yan'an Prefecture to do a good job of current autumn sowing work. Now planting of 127,000 mu of rape has been completed in the province, and as of 15 September more than 970,000 mu of wheat had been planted, including the planting of 510,000 mu of the prefecture's 1 million mu of high yield fields. Yan'an Prefecture planned to increase the area sown to autumn wheat to 1.8 million mu this year, placing emphasis on 1 million mu of high yield fields with a "three fertilizer base that boom." for new breakthroughs next year in wheat output. The prefecture, counties, and communes took a firm grip on preparations for sowing. Throughout the prefecture wheatfields were summer plowed, 1.4 million mu being plowed twice. The area plowed was larger than last year; plowing was done earlier, and harrowing and raking was done carefully. In addition to the considerable amount of mud fertilizer prepared for the wheatfields, more than 23,000 tons of nitrogenous and phosphate fertilizer was made ready. This was more than 8,000 tons more than last year. Commune members exchanged superior varieties among themselves, and seed departments at all levels additionally prepared 8.5 million jin of seeds, which was more than in former years. The prefecture trained more than 30,000 technical personnel for wheat and rape farming, and set up nearly 10,000 science and technology households for the production of wheat and rape. County cadres now in rural villages number more than 2,000. They are propagandizing the spirit of the 12th Party Central Committee, and organizing the masses to do a crash job of planting during the favorable time when the sun has come out after continuously overcast and rainy weather. The wheat seedlings that were planted earlier have begun to appear in green rows.

SUPERIOR WHEAT VARIETIES SUITED TO SHAANXI LISTED

Xian SHAANXI RIBAO in Chinese 19 Sep 82 p 1

[Article: "Superior Wheat Varieties Suitable For Growing in Shaanxi Province"]

[Text] Wheat varieties that do rather well in production in Shaanxi Province and that are suited to the central Shaanxi irrigated region are the following: Xiaoyan No 6, Zhengyin No 1, Xiannong 151, and Abo. Suited to the eastern part of the dry plain to the north of the Wei are the following varieties: Shaanhe No 6, and Weimai No 4; suited for growing in the central section of the province are: 7125, 404, and 4.01. Suited for growing in the western part of the province are Zhengzhou 522, Fengchan No 3 Selected Line, Baolin No 9, Shaanzao No 1, and Wunong 132. Suited to Chuandao Prefecture in southern Shaanxi are Abo, Fanliu, 70 (45), and 6601. Suited to Yan'an Prefecture is No 3. Suited to Yulin Prefecture as winter wheat are Beijing No 10, Nongda 139, and Dongfanghong No 3. All areas may make selections of varieties to be used by adapting general methods to local conditions.

BRIEFS

AUTUMN WHEAT SOWING--Inspired on by the spirit of the 12th Party Central Committee, the Weinan Prefecture State Farm and Land Reclamation Bureau has taken firmly in hand work preparatory to the sowing of autumn wheat. As of 7 September, the four state-owned farms in the bureau, Huayin, Shayuan, Chaoyi, and Dali, have made the most of good weather and struggled against rainy, overcast weather to complete plowing within only a week of more than 80,000 mu of land reserved for the growing of wheat that had not yet been plowed or planted, plowing more than 10,000 mu each day. Most of it has also been readied for planting. The Chaoyi Farm flour mill took responsibility for seed selection for the 11 vocational stations throughout the farm. They surmounted difficulties resulting from irregular supply of electricity, and by 6 September completed the task of selecting 2.2 million jin of wheat seeds, 15 days earlier than had originally been planned. The more than 6 million jin of wheat seeds required by the farm have been made ready. More than 200 tractors, and more than 160 seed sowing machines have been substantially checked and repaired. Two thousand eight hundred tons of chemical fertilizer have also been hauled in. [Text] [Xian SHAANXI RIBAO in Chinese 16 Sep 82 p 11] 9432

YANTAI PLANTS ENLARGED AUTUMN WHEATFIELDS ON TIME

Jinan DAZHONG RIBAO in Chinese 25 Sep 82 p 1

[Article: "Yantai Prefecture Plants Enlarged Autumn Wheatfields On Time. Continues Struggle Against Drought Under Inspiration of Spirit of 12th Party Central Committee"]

[Text] Under the inspiration of the spirit of the 12th Party Central Committee, the broad masses of cadres and people in Yantai Prefecture have continued to carry out a deepgoing struggle against drought, using every available means to plant a sufficient amount of wheat well so as to create conditions for bringing in a bumper harvest in agriculture next year.

This prefecture has had 5 consecutive years of drought, and though it rained several times this year, precipitation was spread unevenly, and 10 counties and municipalities gained no relief from the drought. The drought has gone on for the past 9 months, and even in several counties where rainfall had been fairly great, drought has set in making it extremely difficult to do fall sowing.

In the process of studying 12th Party Central Committee documents, the Yantai Prefecture CPC Committee related study to realities in a discussion of the problem of hastening development of agriculture. They believe that Yantai Prefecture should realize ahead of time the strategic objective proposed by the CPC Central Committee of tripling gross output value of agriculture before the end of this century. In order to realize this objective, the great spirit of the 12th Party Central Committee must be the driving force, and a good basis has to be layed for achieving a bumper summer harvest next year by starting now to struggle against drought to plant a sufficient amount of wheat well. The prefecture decided that the fall planted area this year should be enlarged by from 20 to 30 percent over last year's 6.3 million mu.

In order to do a good job of fall planting this year, comrades in charge at all levels of the party and government assigned full responsibility for task completion on individual tracts in a system of responsibility. Throughout the prefecture more than 12,000 cadres were organized to go to the frontlines to take charge of the three autumn production jobs [harvesting, plowing, and sowing]. There they took the lead in propagandizing the great spirit of the 12th Party Central Committee and in building confidence in the fight against drought. They devoted attention to bumper yield plots, did a good job of planting ordinary fields, assigned workforces in a rational way, accelerated building of water conservancy projects, and did everything possible to provide more sources of water to fight drought.

While fighting drought to do fall planting, inasmuch as the harvesting of crops had been delayed this year, Yantai Prefecture adapted general methods to local situations to take commensurate steps, to race against time, to seize the initiative, and to sow as early as practicable. They harvested, fought drought to create soil moisture, plowed, harrowed, and sowed all at the same time. They parted from past sole reliance on machine methods to use a combination of manpower, machinery, and draft animals. All counties proceeded from the drought situation and proceeded from the need to make commensurate changes in the farming system increase the planting of wheat in large furrows.

In fighting drought to do autumn sowing, this prefecture instituted specialized contracting responsibility systems centralized in several ways as key measures. More than 9,800 production brigades in the prefecture instituted wheat production systems of responsibility, more than 6,600 of them instituting specialized contracting systems specialized in several ways. This amounted to 67 percent of all brigades. As of 23 September, the prefecture had sown more than 1.5 million mu of wheat, more than 500,000 mu more than during the same period last year.

SHANDONG

TAIAN PREFECTURE COMPLETES WHEAT PLANTING

Jinan DAZHONG RIBAO in Chinese 2 Oct 82 p 1

[Article: "Taian Prefecture Fulfills Wheat Sowing Plans on Time. Great Spirit of 12th Party Central Committee Stirs Enthusiasm of Masses. Following Completion of Autumn Planting, Shouguang County Seizes Opportunity to Inspect Seedlings and Augment Plantings to Assure a Full Stand of Seedlings"]

[Excerpt] As of 29 September, except for some wheatfields to be planted to a late crop, and some where planting is to be expanded, planting of a planned 3.5 million mu of wheat in Taian Prefecture had been completed on time. Quality of sowing was better than last year.

During the planting season, the Taian Prefecture CPC Committee and government administrative offices organized 4,100 cadres at all levels to go down to the grassroots to lead the broad masses of commune members in study of documents from the 12th Party Central Committee, and to use the spirit of the 12th Party Central Committee to guide the planting of wheat. As a result of study of 12th Party Central Committee documents, cadres and commune members in Dongping County understood the magnificant objectives and strategically key points for the future, which has tremendously stirred their enthusiasm for the planting of wheat.

After fulfilling plans for the sowing of 350,000 mu of wheat, the county revised its planting plans and got ready to sow an additional 50,000 mu. Laifu County cadres and commune members, their minds filled with the magnificent objectives, took firm hold of current production, and improved quality of wheat sowing. While selecting superior varieties and applying sufficient base fertilizer, they zeroed in on the dry weather and the serious lack of soil moisture in the fields using every available means to bring up soil mositure or create soil moisture until they got sufficient moisture for planting. At a previous time, some commune members in Taian County were apprehensive about changes that might take place in the system of responsibility of "double contracting" [household contracting of fixed output quotas and responsibility for task completion]. They did not want to put in more work or add fertilizer to the wheatfields. But after reading Comrade Hu Yaobang's report to the 12th Party Central Committee on establishment of various forms of rural production responsibility systems and the need to maintain them for a long period of time, their minds were at ease, and they applied sufficient base fertilizer without worry and planted wheat well to get increased yields. As of 29 September the entire county had completed the high quality sowing of 480,000 mu of wheat.

TITLE: "On a Suitable Concentration of Economic Crops"

SOURCE: Beijing NONGYE BUJU YU QUHUA [AGRICULTURAL DISTRIBUTION AND ZONING] in Chinese Mar 82 pp 208-214

ABSTRACT: The principle underscoring the practice of regional specialization of economic crops is to cultivate crop to suit the land. Under this principle, the condition influencing the distribution of economic crops must be concretely analyzed to resolve the problem of the extent of possible concentration in the region suitable for a given economic crop. The paper proceeds to analyse the natural, economic, and distribution characteristics of rubber, sugar cane, cotton, rapeseed, and kenaf [ambary.] The major problems in the arrangement of economic crops in China include a gradual reduction of scattered acreage, primarily due to competition of land between grains and economic crops. In view of these problems, the natural condition of a given region should be the first consideration.in so far as whether it is more suitable for grains or more suitable for a given economic crop. In order to ascertain the proper degree of concentration, 2 types of indices may be used: (1) The absolute index, reflecting the percentage of an economic crop in the total cultivated acreage. For example, the 144,000 mu of cotton in Hua County of Henan amount to 8.3 percent of cultivated land; the 75,000 mu of cotton of Qi County of Henan amount to 20.8 percent, qualifying the latter as a region of concentrated cotton production. (2) The relative index, expressed by computing the ratio of an

[continuation of NONGYE BUJU YU QUHUA Mar 82 pp 208-214]

economic crop in the cultivated acreage, the rate of commercial products in the crop, the price structure of the product, the labor structure, and the investment structure. A mathematical model is provided to compute the suitable ratio of cotton in the cultivated acreage from the known data of A-the cultivated acreage, P-the farming population, A_p-the per capita cultivated land, G-the unit yield of grain, G_p-the per capita grain consumption, G_s-the rate of self-sufficiency of grain, I-the unit yield of cotton, I_s- the amount of cotton production retained by individuals, I_c- the rate of commercial cotton, R-the acreage of crops other than grains and cotton, N-the rotation cycle of the cotton crop. The method of using the mathematical model to compute the theoretical [optimal] ratio of cotton in the cultivated acreage is explained. Through a comparison between the theoretical ratio and the actual ratio, it will be easy to decide whether a region is overly concentrated on cotton production or whether the cotton acreage should be expanded to take advantage of the cotton production potential. The mathematical model concerns the existing material foundation for a given economic crop, which the paper refers to as its technical and economic conditions. The natural conditions for the crop are implied but not specifically contained in the equations because, as the paper states, the nautral conditions conducive to economic crops are usually conducive to grain crops also. [This argument appears to contradict directly with the reasoning of the first chapter of the paper.]

TITLE: "Weather Condition for Prevalence of Scab Fungus and Long Term Forecasting"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 9, 10 Sep 82 pp 25-27

ABSTRACT: Wheat scab disease is a worldwide disease related to the weather. In central and southern Hubei, especially on the banks of lakes and rivers, its incidence is high and damage severe. Based upon etio-biological and epidemiological data of this disease, the paper proceeds with a comprehensive analysis of the condition of weather during the crop development period, especially the stage when the wheat is sensitive to the disease. A large number of artificial inoculation tests proved that wheat is the most susceptible to scab during the blooming stage and left-over pollens form the bridge to infect the wheat spike. Rainy weather during the blooming stage encourages scab spores to invade the wheat and if high humidity is maintained for 36 hours under 25°C, the spikes will be infected. Following an extensive analysis of meteorological factors, the paper concludes that in Hubei, the period of middle Apr to middle May is the susceptible stage of wheat and proposes a 3-factor (quantity of rain, number of rainy days, and hours of sunlight) index of the period to be used to forecast the severity of scab. The validity of the forecast is, of course, determined by correct forecast of the 3 meteorological factors.

TITLE: "Severe Drought in Northeast and Northwest and an Overabundance of Precipitation in North China and South of Changjiang--June 1982"

SOURCE: Beijing QIXIANG [METEOROLOGICAL MONTHLY] in Chinese No 9, 10 Sep 82 pp 45-47

ABSTRACT: This is the column "Monthly Weather" for Jun 82, prefaced by a general description of the weather conditions of the various parts of China. In Northeast and Northwest, the dry weather of the previous period persisted throughout the month of Jun, with rainfalls less than 40 mm, about 60-80 percent below normal. The temperature was abnormally high to cause the drought to be further aggravated. In Hebei, Shandong, and N. Jiangsu, rainfalls reached 60-170 mm, 10-50 percent more than normal. In central Hunan and central Jiangxi, the rainfalls reached 300-500 mm, also 10-50 percent above normal. There were 3 typhoons in Jun, 1.2 more than normal, but not a single one reached the China coast. The above general description of the month is followed by analyses of the circulation characteristics, the cold vortex process in N. China, and the continuous rainstorm weather of the region south of the Yangzi River.

OFFICIAL ON CHINA'S AGRICULTURAL POLICIES

OW241222 Beijing XINHUA in English 1129 GMT 24 Nov 82

[Text] Beijing, 24 Nov (XINHUA)--Agricultural taxes will not increase when Chinese peasants achieve better harvests. This is a basic policy of China's to boost agricultural growth, a senior official of the Ministry of Agriculture, Animal Husbandry and Fishery said today.

Liu Jinmin, a deputy bureau director of the ministry, said that in 1981, such taxes accounted for 2.93 percent of the nation's agricultural income, compared to approximately 12 percent in the early 1950's. He is taking charge of an international symposium on integrated rural development now held jointly by the Chinese Government and the United Nations Development Program in Huangxian County, Shandong Province.

Agriculture is the foundation of the national economy, Liu Jinmin said, and as such, had a strategic priority in the country's development plan. The Chinese Government has had a clearer view of this since 1979. Despite financial difficulties over the past few years, annual state allocations for farmland improvement during the 1979-1981 period was more than double the figure for 1966, and 52 times as many as in 1952.

The government since 1950 has cut the prices of chemical fertilizer and insecticide on six occasions and farm machinery on ten occasions. Meanwhile, Liu Jinmin said, the purchasing prices for farm produce had been raised. In 1979, for example, prices for 18 major products including grain, cotton, edible oil and pigs were raised by an average of 24.8 percent.

the increase in the purchasing price of grain was 20 percent, he added. An additional increase of 50 percent had since been granted for grain sold to the state beyond quotas. From 1979 to 1981, Chinese peasants received an extra income of 46,290 million yuan as a result of the increased purchasing prices.

China is a developing country and had limited financial capabilities, Liu Jinmin explained. Eighty percent of its population are concentrated in the countryside. Because of this, it was all the more important for it to rely on the people's initiative for faster economic growth.

While trying to provide peasants with more assistance and benefits, he said, the Chinese Government has adopted new policies since 1979 to boost peasant enthusiasm for production. The use of science to raise output was being encouraged, he said.

The latest policies include:

--More decision-making power to production teams, the basic accounting units of the people's communes. In other words, said Liu Jinmin, production teams now have the power to decide independently on when and where to grow crops best suited to local conditions, and use methods that they think are the best to increase and diversify production.

--The job responsibility system of various forms, under which production is carried out on a household basis, or by individual labourers or smaller but specialized groups. This helps eliminate egalitarianism in distribution, as payment is made according to output.

--More freedom to peasants in their economic activities. Peasants are now encouraged to engage in domestic sideline production provided they fulfill collective production tasks. Plots allocated to peasant households for their private use have been expanded and rural fairs opened everywhere.

'RENMIN RIBAO' VIEWS ECONOMIC RESULTS IN AGRICULTURE

HK250152 Beijing RENMIN RIBAO in Chinese 20 Nov 82 p 3

[Article by Sun Xupei [1327 2485 1014]: "Results Mean Speed--Sidelights of Discussion on Economic Results in Agriculture Conducted by the Chinese Agroeconomics Society"]

[Text] To attain the strategic objective of quadrupling the gross value of industrial and agricultural production, we should pay special attention to enhancing economic results. Without this prerequisite, speed means nothing.

The 1982 second congress of the Chinese Agroeconomics Society and the academic discussion recently held in Hefei stressed the above view. In a proposal raised by more than 300 participants at the end of the congress, the slogan of "time means wealth and results mean speed" was put forward.

All the experts maintained that economic results refer to the relationship between work achievements and consumption. To attach importance to economic results means that with less investment, we should produce more. In other words, with less material labor and animated labor such as land, capital, manpower and so forth, we should produce as many products as possible and a wealth of agriculture, forestry, animal husbandry and so forth to meet society's demands.

Since the 3d Plenary Session of the 11th CPC Central Committee, the production responsibility system has been extensively implemented. Since then, we have succeeded in eradicating the evils of "great tumult" and "eating out of a big pot." From the angle of production relations, we have enhanced economic results in agriculture. However, due to the influence of long standing habits, the phenomenon of neglecting economic results is still a serious one and can be found here and there. Various manifestations of this were enumerated by comrades who spoke at the meeting:

--Some localities have reaped good harvests. However, there are still poor production brigades and poor peasant households despite the increase in production. This is due to the low results on account of the unitary system of production and irrational economic structures.

--According to figures issued by a certain province, more and more agricultural regions in the province have set up industry. However, one-third of the efforts have been to no avail, because the province failed to find a way out for the superfluous labor force which increased year by year. Since the labor force was not properly used, economic results decreased.

--In one area, the average mechanical power per mu of land reached the world advanced level. However, the peasants' intensity of labor in the farmland remained unchanged because of improper administration and management, which led to low results in the utilization of machinery.

--Some localities cut down a great number of sucarcanes, but were unable to send them to sugar refineries. Some localities caught a large amount of fish, but they spoiled before reaching the consumers' dining tables. This was because of too many barriers and the blocking up of the circulation of commodities. This hampered the act of bringing the role of economic results into full play.

Enhancing economic results is an important question for study and much work ought to be done in order to solve this question. Where should our main efforts be exerted? All the participants maintained that the ideas of "three more and three less" put forth by Du Runsheng, director of the research group for the rural policy of the CPC Central Committee, were sound and to the point: 1) We can produce more grain by cultivating a smaller area of farmland. Ours is a country with a vast population and limited farmland and we have only 1.5 to 2 billion mu of cultivated land. By the year 2000, our grain output will reach 920 to 960 billion jin. To attain this objective, we should enhance the yield per unit area of all our cultivated land to the level of high-yield areas. This means that we should maintain the output of high-yield fields, raise the output of medium-yield fields, reform low-yield fields and do everything possible to enhance the economic results of medium-yield and low-yield fields. 2) We should produce more meat by consuming less grain. At present, we allot 100 billion jin of grain annually as fodder. We cannot afford to allot more grain for this purpose. To produce more pork, beef, mutton, fish, chicken and eggs, we should devote our efforts to the production of mixed fodder. The most important method is to plant more grass. 3) We should get more done with less money. We are now in a period of financial readjustment. It is impossible for the state to allot more money to assist agriculture. Therefore, we should always proceed from reality and refrain from "doing things arbitrarily." Instead, we should "work out plans" before doing something. In so doing, we can avoid wasting money and manpower.

The issue of enhancing economic results reminded some comrades of the former "four modernizations" characterized by the intense concentration of funds and technology. These "four modernizations" mean modernization in machinery, water conservancy, the chemical industry and electric equipment. The comrades sighed with regret because it was difficult to realize these modernizations because of the lack of funds. At the discussion, many comrades said that the former "four modernizations" should be gradually realized. However, at present there are many ways to enhance economic results without investment or too much investment. A delegate from Heilongjiang said that in Hailun County located in the Songnen plain, the output of corn and soybean in 1979 increased by 11.6 million jin and 14.8 million jin respectively because they were transferred from unsuitable to suitable areas. In the past 3 years, the annual output value and net output value of each and every agricultural worker in agriculture and grain output have increased by 18.9 percent, 21.8 percent and 10.4 percent respectively compared with the previous 3 years. This county which was formerly called "a donkey lying on the ground calm and collected" has now stood up and made a gigantic step.

To enhance economic results in agriculture, it won't do to sit idle and engage in talk alone. Practical action is needed. Professor Zhu Dianyu of the Xinjiang 1 August Agricultural Institute talked about strange phenomenon occurring in the production of fruit, eggs and wool. Pears produced in Korla County are well-known. A large quantity of them rotted in the county. However, they are not available on the market of Urumqi. Instead, the municipality had to import pears from Tianjin. Last year, Xinjiang imported 1,200 tons of eggs from other provinces. In the business transactions of eggs, Xinjiang lost 0.67 yuan for each jin of eggs. However, the province would rather lose money than financially support local masses to raise chickens to solve the problem of supplying eggs locally. It would rather ask woolen mills in cities to send lorries to pastures which are several hundred kilometers away to take wool back than install those simple technological facilities in the pastures for washing wool. The present method of taking wool from pastures and sending it back to the cities is causing enormous waste, because after washing, only half of the crude wool is left. Apart from that, gasoline is wasted and the cities are polluted. This professor added: It is difficult to solve this problem. However, the difficulties are not insurmountable. The key lies in having a great number of cadres who are devoted to their work and are determined to carry out reform. They should be bold in creating a new situation and use their brains to think and propose measures and the ways to implement them.

Developing science and technology is the fundamental way for enhancing economic results in agriculture. Therefore, agrotechnical workers should realize that they are shouldering important tasks. Gu Huangzhang, a lecturer of Nanjing Agricultural Institute, said: Any strategic decisions guiding agricultural production should be based on the sciences. It is the responsibility and duty of agrotechnical workers to promote this practice. We once argued over where we should mainly spread chemical fertilizers--Suxhou or Xuzhou? After making an indepth investigation and scientific analysis, we discovered that due to the previous excessive application of chemical fertilizer in the Suzhou area and the excessive spread of nitrogenous fertilizer by about 30 percent, soil properties of the area were undermined. Compared with 1976, the application of chemical fertilizer per mu of farmland increased by 170 percent in 1981, but per mu yield of farmland dropped by 276 jin. In the meantime, after analyzing the relations between chemical fertilizer application quantity, per mu yield and output value, we discovered that the average application quantity of chemical fertilizer to per mu of farmland by the Zuzhou area is the most appropriate. Therefore, we concluded that while increasing the application of organic fertilizer in the area, we may scores [as printed] of jin of additional chemical fertilizer to each mu of farmland to achieve the best economic results. The Jiangsu Provincial Scientific Commission distributed relevant materials on enhancing economic results of chemical fertilizer to various counties and communes so that the broad masses of peasants could know how to derive more benefits with less money.

Associate Professor Wei Shuangfeng of the South China Agricultural Institute, who did his utmost to overcome obstructions as early as at the end of the 1950's to persist in studying economic results in agriculture, said: Good management methods can bring about economic results only when they are directly mastered by practitioners. Therefore, it is the responsibility of scientific workers in the field of agroeconomics to rapidly spread scientific knowledge to the vast rural areas. We should set up our simple and convenient agroeconomic index system which is in accord with our national conditions and can be mastered by rural cadres who have attained a secondary educational level. In recent years, he has given lectures on scientific knowledge for enhancing economic results in agriculture for cadres of the province, prefectures, counties and communes and has achieved marked results in effectively guiding some localities to carry out rotation between dryland and paddy rice and reform low-yield land.

RURAL ENVIRONMENTAL PROTECTION WORK PROGRESSES

OW140730 Beijing XINHUA in English 0705 GMT 14 Nov 82

[Text] Beijing, 14 Nov (XINHUA)--China has set up rural environmental protection and monitoring stations in 14 provinces and municipalities, according to the Ministry of Agriculture, Animal Husbandry and Fishery.

The Rural Environmental Protection Agency of the Ministry recently called a meeting in Harbin to discuss work on rural environmental protection and monitoring. Directors of the 14 stations and officials in charge of the work attended this meeting.

In recent years, the stations have provided a large quantity of scientific data to help the government to formulate laws on protection of farmland, forestry, water resources and grassland.

Under the auspices of the Ministry, the gathering was told the stations and the Rural Environmental Protection Agency have conducted considerable scientific research and experimentation, upon which they have based new standards for safe use of pesticides, air quality, potable water and irrigation water.

In the wake of increased industrial development, pollution loomed large in some areas, especially the areas near centers of the chemical, metallurgical and paper-making industries. For example, the officials learned, the incidence of diseases for both human beings and animals near the Baotou Steel Plant in Inner Mongolia has risen as a direct result of air pollution.

To deal with this problem, China began to set up Rural Environmental Protection and Monitoring Stations in 1979.

After just a few years' effort, the monitoring stations in Heilongjiang, Shandong and Zhejiang Provinces surveyed pollution by industrial pollutants and pesticides. They reported the results of survey to local governments and higher authorities, promoting the adoption of measures dealing with pollution.

The agency said the monitoring stations have also studied background values of rural environment for better monitoring and appraisal of rural areas.

Associated background values include various data about the soils, water, crops and other materials that are free from pollution. With the data, they can appraise the environment and pollution with uniform standards.

The agency, which is under the Ministry of Agriculture, Animal Husbandry and Fishery plans to set up monitoring stations in all of China's provinces, autonomous regions and municipalities in coming years. Based on this work, the agency expects to establishing monitoring centers and finally build up a national network with advanced equipment and more scientists.

In recent years, China has instituted various laws to protect the environment, natural resources and maintain the balance of nature.

REPORT ON NEW FOOD HYGIENE LAW

Decree Issued

OW201008 Beijing XINHUA Domestic Service in Chinese 0159 GMT 20 Nov 82

[Text] Beijing, 20 Nov (XINHUA)--Decree of Standing Committee of Fifth NPC of the PRC:

No 12

The "PRC Food Hygiene Law (for trial implementation)" has been approved by the 5th NPC Standing Committee of the PRC at its 25th session on 19 November 1982. It is hereby promulgated and will be implemented on a trial basis as of 1 July 1983.

Chairman of the NPC Standing Committee Ye Jianying

19 November 1982.

Law Adopted

OW221200 Beijing XINHUA Domestic Service in Chinese 0709 GMT 20 Nov 82

[Text] Beijing, 20 Nov (XINHUA)--Food Hygiene Law (for trial implementation) of the People's Republic of China

(Adopted by the 25th session of the 5th NPC Standing Committee on 19 November 1982)

Chapter I: General Rules

Article 1

This law is formulated for the purpose of insuring food hygiene, preventing food poisoning and other harmful elements that pose a danger to the human body, safeguarding the people's health and enhancing the fitness people of all nationalities.

Article 2

The state enforces a food hygiene supervision system.

Article 3

Everyone engaging in food production and food business operations within the People's Republic of China should observe this law. Everyone has the right to expose and file charges against a violation of this law.

This law applies to all food items, food additives, food containers and packing materials, food utensils and equipment; it also applies in food production and operations sites and facilities and related environments.

Chapter II: Food Hygiene

Article 4

Foods should be free of poison, harmless, meet expected nutrition requirements and appeal to sight, smell and taste.

Article 5

Staple and supplementary foods exclusively for infants and young children must meet the nutrition and hygiene standards set by the public health administrative departments of the State Council.

Article 6

The following hygiene requirements must be met during the process of food production and operations:

1) Maintain a neat and clean interior and exterior environment; take measures to eliminate flies, mosquitoes, cockroaches and other harmful insects and their breeding grounds; maintain a required distance from any poisonous or harmful sites.

2) A food production or operations enterprise should be equipped with workshops and storerooms for treating, processing, packing and storing raw foods materials that are compatible with the varieties and quantities of the foods produced.

3) There must be necessary facilities for disinfection, clothes changing, washing, natural light, lighting, ventilation, preservation, prevention against dust, flies and rats, water purifying, sewage disposal, and storing garbage and other discarded stuff.

4) Equipment layout and the technological process should be designed to prevent raw and prepared goods and raw materials and finished products from polluting each other. Foods must be kept from coming into contact with poisons or unclear articles.

5) Dining utensils, drinking utensils and containers of foods for direct contact with the mouth must be washed clean and disinfected before use. Cooking and other utensils must be washed and kept clean after use.

6) Packing containers, tools, equipment and conditions for transport, loading and unloading of foods must meet hygiene requirements to prevent pollution of foods.

7) Foods for directoral consumption should be packed either in individual wrappings or with materials that are clean and free of poison.

8) Food production and operations personnel should always maintain personal sanitation. They must wash their hands and wear clean work clothing when doing food production and sales. When selling foods for direct consumption, they must use appropriate tools.

9) Water must meet the respective hygiene standards set by the state for drinking water in urban and rural areas.

Hygiene requirements for food peddlers and businessmen in urban and rural fairs to meet in the process of food production and operations shall be formulated separately by the Standing Committee of the respective provincial, autonomous regional and municipal people's congresses by using this law as a reference.

Article 7

Production and sale of the following foods are prohibited:

1) Food that has become stale, rancid, mildewy, insect-infested or contaminated, has mixed with foreign matter or shows unusual signs of possible harm to human health.

2) Containing poisonous and harmful matters or having been polluted by poisonous and harmful matters which may harm the human body.

3) Containing parasites and micro-organisms that may cause diseases or containing micro-organic toxins to an extent exceeding the limit permitted by the state.

4) Meat and meat products that have not been inspected by a veterinarian for food hygiene or fail to pass the inspection.

5) Poultry, domestic and wild animals and aquatic animals that have died of illness, poison or unknown cause and the products of these poultry and animals.

6) Food contaminated by unclean or seriously damaged containers and packing or by unclean means of transportation.

7) Food that has been mixed with artificial ingredients, impurities or fake food that affects nutrition and hygiene.

8) Food that has been processed from nonfood raw materials.

9) Food for which the date for safe consumption has expired.

10) Food that has been banned for sale by special regulations laid down by health administration departments under the State Council or by the people's governments of various provinces, autonomous regions and municipalities directly under the administration of the central government in order to meet the specific needs for disease prevention.

11) Food that contains additives or insecticide (residual) disapproved by the health administration departments under the State Council.

12) Other food that fails to meet standards or to comply with regulations for food hygiene.

Article 8

Medicine must not be added to food except for traditional food that is considered both food and medicine or in cases where such medicine is added as a condiment or food enricher.

Chapter III: Hygiene Concerning Food Additives

Article 9

Food additives must meet quality standards. They must be manufactured by factories designated by the departments in charge of chemical engineering, light industry, petroleum, forestry, aquatic production and medicine under the State Council and various provinces, autonomous regions and municipalities directly under the central government.

Article 10

It is necessary to produce, market and use food additives according to the standards for hygiene control in the use of food additives. Products that fail to meet the standards and have been produced by factories other than those designated must not be used or sold.

Chapter IV: Hygiene Concerning Food Containers, Packing Materials, and Tools and Equipment for Food Production

Article 11

Food containers, packing materials and tools and equipment for food production must meet hygiene standards and conform with regulations on sanitation control.

Article 12

In the manufacture of food containers, packing materials and tools and equipment for food production, it is essential to use raw materials that meet hygiene requirements. Products must be made so that they can be easily washed, cleaned and disinfected.

Article 13

The production of paper, plastic and rubber products and paint in direct contact with food must be organized by the department specializing in the manufacture of these products.

Chapter V: Establishment of Standards for Food Hygiene and Introduction of Measures for Hygiene Control

Article 14

The national standards with regard to hygiene for food, food additives, food containers, packing materials, and tools and equipment for food production as well as detergents used in purifying food and cleaning tools and equipment for food production and the maximum allowance for contaminants and radioactive materials in food and the measures for hygiene control and the regulations for conducting inspection must be formulated or approved and promulgated by the public health administration department under the State Council.

Article 15

The people's governments in various provinces, autonomous regions and municipalities directly under the central government may set their own local hygiene standards for foodstuffs for which the state has not set any standard. However, they must report their action to the public health administration department of the State Council for the record. With the concurrence of the public health administration department at the same level, the department in charge of food production and management or the enterprise in charge of food production and management may list its food hygiene figures when it outlines product quality standards.

Article 16

Figures of hygienic significance in the national standards for production quality for food additives must be examined and approved by the health administration departments under the State Council.

The appraisal and conclusion on any safety factor of insecticide, chemical fertilizer and other chemicals for farm use must be examined and approved by the health administration departments under the State Council.

Regulations for checking slaughtered poultry and animals for hygiene by veterinarians should be formulated by the related department of the State Council jointly with the health administration departments.

Article 17

Various hygiene standards, measures for sanitation control and measures and procedures for sanitation inspection should be promptly revised according to actual needs or examined and approved by the department that formulated or promulgated these standards, measures and procedures.

Chapter VI: Food Hygiene Management

The department in charge of the enterprise for food production and management is responsible for doing food hygiene work within its own department and checking how this food hygiene law is being enforced.

Article 19

The department in charge of the enterprise for food production and management and the enterprise for food production and management must set up organs for improving food sanitation control and inspection in one's own department or unit or assign full or part-time personnel to take care of food sanitation.

Article 20

Organs for food sanitation control and inspection or personnel in charge of food sanitation control have the following duties:

1. Implement the food hygiene laws and regulations as well as the rules and regulations in this regard; and organize the training of personnel for food production and management.

2. Carry out sanitation control, inspection or checkups on food processing and food production and management.

3. Supervise work for food hygiene, criticize and impede actions that have violated the food hygiene laws and regulations, report the situation to the unit at the higher level and to the supervisory organ for food hygiene and propose measures on how to these actions. [as printed]

Article 21

In building new enterprises for food production and management and expanding and remodeling such enterprises, it is necessary to select sites and come up with designs that conform to hygiene requirements. The work of examining and approving these designs and of checking and accepting a completed project must be accomplished by a food hygiene supervisory organ.

Article 22

Before an enterprise for food production and management engages in full-scale production of new varieties of food and food additives by means of new resources, it is necessary to show data needed for the hygienic and nutrition appraisal of these new products. Before an enterprise for food production and management engages in full-scale production of new food containers, packing materials and tools and equipment for food production by utilizing new, raw and other materials, it is necessary to show data needed for the hygienic appraisal of these products. Prior to the full-scale production of the aforementioned new products, it is essential to provide samples for examination and approval according to the proper procedure to make sure that the new products meet the specified food hygiene standards.

Article 23

Food in fixed packages and food additives must be accompanied with a booklet of directions on the product or stamped with a trademark. The name of the product, place of origin, name of factory, date of production, lot number (or code number), specifications, prescription or the main components, date of expiration for safe consumption and methods for eating the food and using the food additives must be clearly marked on various different products according to the regulation. No exaggeration or false advertisement may be used in the booklets or on the trademarks attached to the food or food additives.

Article 24

In the process of food procurement, those who are engaged in food production and management must demand that a certificate of quality or a laboratory test report be produced according to the related state regulation. The scope and type of food that calls for the certificate of quality is determined by the health administration departments in various provinces, autonomous regions and municipalities directly under the central government.

Article 25

Personnel in food production and management must undergo physical checks every year. Those who seek jobs in this field or have been temporarily transferred to work in the field must undergo physical checks and obtain a certificate of good health before they can start work.

Those suffering from dysentery, typhoid, infectious diseases in the digestive system such as viral hepatitis (including disease carriers), active tuberculosis, suppurating or bleeding skin diseases and other diseases that violate food hygiene are not allowed to participate in work where they would have contact food for direct consumption.

Article 26

Enterprises engaged in food production and management and food merchants and vendors must obtain a sanitation permit before they submit applications for registration with the industrial and commercial administrative department or change their registration.

The measures governing the issuance of sanitation permits should be worked out by the health administration departments of various provinces, autonomous regions and municipalities directly under the central government.

Article 27

The industrial and commercial administrative department is held responsible for controlling food hygiene in rural and urban trade fairs and for checking food in general for sanitation. The food hygiene supervisory organ is held responsible for supervising the work of food hygiene and food inspection. The department of agriculture, animal husbandry and fishery is held responsible for checking animals and poultry for hygiene by veterinarians.

Article 28

Imported food, food additives, food containers, packing materials and tools and equipment for food production must conform to the state hygiene standards and measures for sanitation control. The aforementioned imported products must be watched and inspected by the food hygiene supervisory and inspection organ at the border. In requesting inspection, the unit that imports the products should provide data from the export nation (region) and its test reports on the insecticide, additives and fumigants used.

The customs office will release goods on the basis of the certificate issued by the food hygiene supervisory and inspection organ at the border.

Article 29

Food for export shall be subject to hygienic supervision and inspection by state export inspection departments.

Clearance shall be given by customs officers to food for export on the basis of inspection certificates issued by the state export inspection departments.

Chapter VII: Supervision Over Food Hygiene

Article 30

Public health administration departments at all levels shall lead the work of supervision over food hygiene.

Article 31

Sanitation and antiepidemic stations or food hygiene supervision and inspection institutes at or above the county level under public health administration departments are organizations responsible for supervision over food hygiene that comes within their jurisdiction.

Railroad, communications, factory (farm) and mine sanitation and antiepidemic stations shall perform the function of a food hygiene supervision organization within the scope of their jurisdiction and accept work guidance from local food hygiene supervision organizations.

Article 32

Food hygiene supervision organizations shall have food hygiene supervisors who shall be qualified professional personnel with certificates issued by people's governments at the corresponding levels.

Supervisiors of railroad, communications, factory (farm) and mine food hygiene shall be issued certificates by responsible institutions at a higher level.

Article 33

The responsibilities of a food hygiene supervision organization are:

1. To monitor and inspect food hygiene and give technical guidance;

2. To help train personnel engaged in food production and marketing and supervise their physical examination;

3. To disseminate knowledge of food hygiene and nutrition, evaluate food hygiene and make public the conditions in food hygiene;

4. To hygienically examine the sites and designs for the building, extension or rebuilding of enterprises engaged in food production and marketing and take part in checking and approving such projects;

5. To investigate cases of food poisoning and contamination and take control measures;

6. To conduct on-the-spot inspections, give itinerant supervision and in a timely manner handle the problems discovered;

7. To investigate acts in violation of this law and take disciplinary sanctions against those responsible in accordance with the law; and

8. To be responsible for handling other matters related to supervision over food hygiene.

Article 34

Food hygiene supervisors shall carry out the tasks assigned them by food hygiene supervision organizations.

While carrying out their tasks, food hygiene supervisors may acquaint themselves with the situation of those engaged in food production and marketing, ask for necessary information, enter places of food production to conduct inspection and obtain free food samples in accordance with the regulations. Those engaged in food production may not refuse to let them do so or hide facts from them.

Food hygiene supervisors have the obligation to keep secret the technical information provided by those engaged in food production and marketing.

Article 35

In addition to food hygiene supervision organizations, public health administration departments under the State Council or the authorities of provinces, autonomous regions or municipalities directly under the central government may, as needed, designate qualified units as food hygiene inspection units which shall conduct food hygiene inspections and issue inspection reports.

Article 36

In addition to taking emergency treatment measures, units where cases of food poisoning take place and units that treat patients suffering from food poisoning shall report such cases to local food hygiene supervision organizations in a timely manner and in accordance with the relevant state regulations.

Chapter VIII: Legal Responsibility

Article 37

Food hygiene supervision organizations may take the following disciplinary sanctions against relatively serious violators of this law:

1. Give the violators a warning and require them to make improvements within a stated time;

2. Order them to recall those products sold that are not permitted to be produced or marketed;

3. Confiscate or destroy foodstuffs or food additives that are prohibited from being produced or marketed;

4. Impose a fine of not less than 20 yuan up to not more than 30,000 yuan;

5. Order violators to suspend their operation in order to make improvements, and

6. Revoke their hygiene licenses.

Revoking a hygiene license or imposing a fine of more than 5,000 yuan must be approved by a people's government at or above the county level.

Various disciplinary sanctions may be applied separately or simultaneously.

Food hygiene supervision organizations shall supervise the handling of confiscated articles.

Article 38

In case the party concerned refuses to accept a disciplinary sanction imposed by a food hygiene supervision organization, it may bring a suit against the organization at a people's court within 15 days after receiving notice of the sanction. But the party concerned must promptly carry out the decision on food control. If the party concerned fails to carry out the decision on a fine and fails to bring a suit before the time limit, the food hygiene supervision organization shall ask the people's court to enforce the decision in accordance with the PRC law of civil procedure (for trial implementation).

Article 39

Those who violate this law and cause food poisoning accidents or other food-related diseases shall be responsible for compensation for the losses. Victims have the right to demand compensation for their losses.

Compensation for losses includes medical expenses, wages for lost working time, living allowances, funeral expenses and expenses to compensate bereaved families.

Article 40

Requests for compensation for losses shall be handled by public health administration departments at or above county level. In case the party concerned refuses to accept a decision by public health administration department, it may bring a suit at a people's court. The victim, or his or her agent, may also directly sue the party concerned at a people's court.

A request for damages should be filed within a year beginning from the day the victim or his or her agent becomes or should become, aware of the losses the victim suffers. A request of this type, filed after the time limit, shall not be accepted.

Article 41

Those who violate this law and are directly responsible for serious food poisoning accidents or other serious food-related diseases resulting in deaths or people's loss of their ability to work as a result of physical deformity, shall be investigated for their criminal liability in accordance with their different circumstances and Article 114, 164 or 187 of the PRC Criminal Law. Those whose cases are minor may be exempted from criminal sanctions in accordance with the PRC Criminal Law, and disciplinary sanctions shall be taken against them by responsible institutions at the latter's discretion.

Chapter IX: Supplementary Articles

Article 42

The public health administration department under the State Council shall draw up detailed implementation rules and regulations in accordance with this law and put them into practice after reporting them to the State Council for approval.

Article 43

Terms used in this law are defined as follows:

Food: referring to various finished products and raw materials for human consumption, as well as articles which are traditionally both food and medicine, but exclusive of articles for medical purposes only.

Food additives: referring to chemosynthetic or natural materials added to food to improve its quality, color, smell and taste or for preservative and processing purposes.

Food enrichers: referring to food additives, natural nutrients or synthetics similar to natural nutrients, added to food to enrich it.

Food containers and packing materials: referring to articles made of paper, bamboo, metal, enamel, ceramic, plastic, rubber, natural fiber, chemical fiber or glass and used to pack or hold food, as well as coating which comes in contact with food.

Food utensils and equipment: referring to machines, pipes, conveyer belts, containers, utensils and tableware which come in contact with food in the process of its production and marketing.

Food production and marketing: referring to such activities as the production (exclusive of planting and breeding), gathering, procurement, processing, store, transport, display, supply and marketing of all foodstuffs.

Those engaged in food production and marketing: referring to all units and individuals engaged in food production and marketing, including mess halls for workers and staff members and food retailers.

Article 44

Regulations for the management of food exports shall be separately formulated by the state imports and exports inspection departments, in coordination with the public health administration department under the State Council, and with the departments concerned in charge of production.

Article 45

This law shall be put into trial implementation, beginning 1 July 1983.

The day this law is put into trial implementation, the "PRC regulations governing food hygiene" shall be annulled. Where laws and regulations on food hygiene promulgated in the past contradict this law, this law shall be taken as the standard.

CSO: 4007/67

'BEIJING REVIEW' EXAMINES SMALL RURAL INDUSTRIES

HK100531 Beijing BEIJING REVIEW in English No 48, 29 Nov 82 pp 3, 4

[From the "Noted From the Editors" Column by Economic Editor Jin Qi: "Small Rural Industries"]

[Text] Are China's small rural industries of any real economic significance? As these industries are generally characterized by a high rate of raw material and energy consumption and low efficiency, what are their future prospects?

This is a logical question from the perspective of a developed nation. But one needs only look at the realities of the presentday Chinese countryside to appreciate the importance of its small industries.

These industries evolved from traditional handicrafts and small workshops and developed fairly rapidly after the establishment of the rural people's communes in 1958. By the end of 1981, about 725,000 commune- and brigade-run industrial enterprises had been set up, embracing various trades and employing 19.8 million workers. Their annual output value totalled 56,200 million yuan, which was one-third of the combined output value of the three-level rural organizations—the commune, the production brigade and the production team.

Small rural industries have had their ups and downs in the last two decades or so, and opinions on them ranged from praise to censure. The late Chairman Mao Zedong described these commune- and brigade-run enterprises as the "hope for a bright future." But in the "great leap forward" of 1958, they became a symbol of a "premature rush to communism" because they were mostly developed by requisitioning the collective property of the peasants without paying any remuneration whatsoever, and during the "cultural revolution" of 1966-76, many of them came under fire as "capitalist undertakings" simply because they were more profitable than grain production. In spite of all this, small rural industries continued to develop and demonstrated their immense vitality. Since China began to right the wrongs in all fields of endeavour in 1978, the total output value of these small industries has increased at a progressive annual rate of 10 percent.

Economically, there are several reasons for this rapid development. First the surplus labour force in the rural areas is expanding and must be employed; secondly, there is an urgent need to tap the abundant mineral and other natural resources, many of which are at present beyond the capacity of big industries in the cities; thirdly, the purchasing power of the vast rural market is increasing; and finally, the rural processing industry, with higher profitability than farm production, can help raise the needed funds for water conservancy projects and farmland capital construction. All these have enabled indigenous small industries to strike root in the rural areas.

They also have become indispensable supplements and auxiliary producers to the big urban industries. In 1981, for instance, some small rural industrial products made up a substantial proportion of the total national output. They produced 19 percent of the nation's coal; 80 percent of its building materials (bricks, tiles, stone, lime, etc.); and 34 percent of its gold. Rural industries also contributed 40 percent of the garment industry's output, and produced a full 70 percent of medium-sized and small farm implements and handicraft articles (basket weaving, embroidery, etc.).

Small industries have helped increase the peasants' standard of living. The output value and fixed assets of commune- and brigade-run industrial and other enterprises each make up over one-third of the total of the three levels of the people's communes. They have, indeed, become a mainstay of the rural collective economy. In 1981, they earned 67,000 million yuan, of which 15,000 million yuan were directly distributed to commune members. This sum was approximately 17 percent of all collectively distributed funds. The rest was set aside as accumulation funds or for the development of collective welfare. These industries are also a chief source of construction funds for the rural areas and towns.

Although they compare unfavourably with big urban industries in technology, management and efficiency, they are nevertheless a cut above farm production which for the most part still depends heavily on manual labour. In 1981, the average per-worker labour productivity of commune- and brigade-run industries was 2,923 yuan, approximately one-fourth of state-run industries but more than five times that of agriculture.

To date, 80 percent of the rural industries are not included in the state plan. They market their own products, bear sole responsibility for their own gains and losses, and are regulated by the market. This has given them much leeway in production and management, but simultaneously resulted in a certain degree of economic disarray such as competition with big industries for raw materials and overlapping construction of factories. It is therefore necessary to strengthen planning, improve their management and gradually raise their technical capabilities. These tasks have been an important aspect of making readjustment in the rural economy in the last few years. Compared with 1980, the number of commune- and brigade-run enterprises dropped by 4.3 percent nationally in 1981, but their total income rose by 11 percent. This indicates that the small rural industries have made remarkable progress in improving their economic results.

Through continuous readjustment and improvement, the rural industries will solve their problems and develop steadily.

'RENMIN RIBAO' ON DEVELOPING ANIMAL HUSBANDRY

HK240835 Beijing RENMIN RIBAO in Chinese 20 Nov 82 p 3

[Commentator's article: "Strive To Improve the Economic Results in Animal Husbandry--Second Comment on Raising the Development of Animal Husbandry to a Higher Position"]

[Text] The RENMIN RIBAO editorial "Raising the Development of Animal Husbandry to a Higher Position" of 4 October pointed out that animal husbandry is at present a weak link in our national economy and there is an urgent need to raise it to a higher position. We must use the same energy as in grasping grain to bring about a great development in animal husbandry.

Where do we begin with developing animal husbandry? Conditions in many localities mean that we should give priority to raising economic benefits and improving the marketability of commodities. Our animal husbandry has developed considerably since liberation and there is a notable increase in the quantity of livestock (amount on hand at the end of the year). In 1980, the quantity of all kinds of livestock in the country had reached more than 580 million heads which represented an increase of 2.67 times over that of 1949. The major problems in animal husbandry at present are poor economic benefits and low marketability of commodities which still lag far behind advanced world levels. According to 1981 statistics, the turn-over rate of pigs from the pen in our country is 63 percent, whereas the advanced world level is from 100 to 200 percent. The turn-over rate of sheep from the pen in our country is about 20 percent, whereas the world level in general is from 50 to 60 percent. In other fields, such as the average livestock meat output and the livestock products output for every 100 mu of grassland, there is still quite a bit of disparity compared with the advanced world level. China leads the world in livestock quantity, but has only one-tenth the grassland area. Moreover, such livestock products as meat, milk and wool are much less than in some countries. This shows that there is still a great latent capacity.

There are many reasons for the low economic benefit of animal husbandry production in our country. An important reason is that for a considerable period in the past, we have onesidedly placed the emphasis on livestock numbers in our guiding ideology and neglected economic benefit. We have not focused attention in raising the turn-over rate from the pen and improving the quantity and quality of end products. Especially in those years of "learning from Dazhai," the quantity of livestock available on hand at the end of the year was the only criterion used for assessing "animal husbandry in Dazhai County," and this was extremely harmful. Many pastoral areas onesidedly concentrated on livestock numbers without paying attention to improving management and administration and raising the scientific level of livestock breeding. The turn-over period of livestock was long and large quantities of livestock were for a long time set in the cycle of "fat in autumn, lean in winter and dead in spring." A great deal of fodder and forage grass was used up without recompense, or, without being turned into such products as meat, milk and wool, not understanding commodity production and not paying attention to improving the marketability of commodities has taught us an important lesson in the directing of animal husbandry work.

The development of our animal husbandry is very unbalanced. The grassland of some of the pastoral areas has still not been fully used and the vast agricultural areas have great potential for developing animal husbandry. For example, such places as northeast China, Sichuan, Yunnan, Guizhou, Henan and Hebei have excellent prospects for developing cattle raising and they must advocate raising more cattle and breeding dairy cows. The grassland of some of the pastoral areas is already overgrazed and must be properly controlled. However, all areas should regard raising economic benefits as their common goal. If we only seek quantitative increase and the marketability of commodities remains very low, it would only mean that the increase is wasted. Without breaking away from the condition of low economic benefit, the pastoral areas cannot become prosperous and the state will also not receive any benefit.

In recent years, such pastoral areas as Fuyun County in the Altay Prefecture of Xinjiang and the Xianghuang Banner of the Nei Monggol Autonomous Region, have already achieved gratifying results by summing up past experiences and lessons and reforming the backward modes of management and production. The Haibei Zang Nationality Autonomous Prefecture, reported in our newspaper today, is an example in this respect. In the past, this prefecture used to regard the amount of livestock available on hand at the end of the year as a major mark for judging production achievements. Some of the livestock were not taken out from the pen and some very old sheep were still kept and not slaughtered. Consequently, the income of the pastoral workers was reduced, the grassland was overgrazed and many livestock lost their foals or died. According to statistics, in the 3 years before 1978, losses due to the loss of foals and death amounted to more than 3 million yuan a year and the pastoral people lost an average of nearly 100 yuan per person. This prefecture is now leading the whole province in the turn-over rate as well as the marketability of commodities, and the pastoral workers' income has greatly increased. This incident has effectively proved that if we shift the focus of work to raising economic benefit, we will grasp the principal contradiction at present of unearthing the internal potential of animal husbandry and further developing livestock breeding. If all pastoral areas can further raise the turn-over rate and the marketability of commodities as in the manner of Qinghai's Haibei Prefecture, they will be able to create considerable wealth.

The marketability of commodities is a composite reflection of numerous production problems. The conscientious study of the problems of raising economic benefit and marketability of commodities can expose many contradictions, promote the solving of these contradictions and push forward the all-round development of production. Raising the economic benefit of animal husbandry is closely related to many fields, of which, the most important are setting up a production responsibility system and eliminating the phenomenon of "eating from the same big pot." Such things as practicing scientific livestock raising, improving breeds and protecting and building grasslands are basic measures for raising economic benefit. After shifting the guiding ideological emphasis to grasping economic benefit, Haibei Prefecture has more enthusiastically, actively and conscientiously grasped this work and adopted effective measures which have caused a profound change to quickly take place in the features of production.

The 12th Party Congress has put forward the grand goal of building up the economy of our country by the end of this century and also pointed out in particular that the development of the economy must be carried out "under the premise of constantly raising economic benefit." The potential of livestock breeding is very great in agriculture, forestry, animal husbandry and fisheries. As long as we conscientiously grasp economic benefit properly, it is entirely possible to achieve a big increase in the output of such livestock products as meat, milk, leather and wool within several years.

DEVELOPING ANIMAL HUSBANDRY REVIEWED

HK060901 Beijing RENMIN RIBAO in Chinese 2 Dec 82 p 4

[Commentator's article: "City Suburbs Must Energetically Develop Animal Husbandry--Third Comment on Raising the Development of Animal Husbandry to a Still Higher Position"]

[Text] After the energetic development of animal husbandry in the suburbs of Harbin, the supply of milk and eggs has been greatly improved and the income of the peasants has also increased. This example has universal significance to many big and medium cities.

There are 80 large and medium sized cities in China that have a population of over 300,000 each and there is a total of 160 million people living in cities and towns. Recently, the material lives of these city civilians have improved markedly and along with the development of tourism and recuperation, the population of cities are gradually increasing. Therefore, to meet the above situation, the need for meat, eggs and milk is also increasing. In some cities, there has been rather a shortage of meat, eggs and milk. How can we resolve this contradiction? It is not a good method to fully rely on allotments from other places. At present, a large amount of these nonstaple foodstuffs of some cities are allocated from other provinces and places. The cost of these foodstuffs are high and the wastage great, thus seriously aggravating the state subsidy and the consumers' burden. Nonstaple foodstuffs, such as eggs and milk should be kept fresh. After a long distance of transportation, these foodstuffs may go bad and cause a loss. For instance, the damage and mould of fresh eggs allocated and transported from Hunan, Hebei, Henan and other places to Beijing and Tianjin Municipalities may reach 20-30 percent or more. Furthermore, the standard of living of the people of towns and villages allocating these foodstuffs has recently improved and their need of these nonstaple foodstuffs is also great. Large cities cannot rely on them for their nonstaple foodstuffs for a long period of time.

The experiences of Harbin and other municipalities teach us that fundamental way of resolving this contradiction is to energetically develop husbandry in city suburbs and countryside and raise the degree of self-sufficiency in domestic animals and poultry products. There are many favorable conditions for city suburbs to develop animal husbandry. In the suburbs of the 80 large and medium sized cities, there are 130 million mu of cultivated land. Most of this land is in a good condition and there are high yield fields which can offer abundant forage. In addition, there is a large amount of straw and dregs of rice cakes that can be used to feed domestic animals and poultry. In the suburbs of a number of cities, there is a certain amount of mountainous, hilly areas and grasslands or water surfaces, which is rich and abundant in herbage and which provides a favorable condition for producing protein and aquatic fodder. In the industrial and commercial enterprises of the cities, there are large quantities of leftover bits and pieces such as distillers' grains, bagasse, grits of flour and soybean residue that can be used as fodder. Moreover, in most of the cities, there are state or collective run stock and poultry breeding farms, livestock farms and feed processing plants that have strong forces in livestock scientific researches. The vast number of suburban peasants also have initiative and experience in raising livestock in family units. Provided we make full use of these favorable conditions, it will not be difficult to develop animal husbandry in city suburbs.

Some comrades say that the area of the suburbs is limited compared with a large city, so it is useless to attempt to develop animal husbandry in city suburbs and this cannot solve the needs of the city. On the short supply of eggs, milk and other products, they looked more at objective difficulties, but never thought of a way to exert their superiority and try to overcome the difficulties. It was precisely because of the influence of these ideas that some cities failed to step up the self-sufficient production of milk, eggs and meat, thus resulting in the short supply of these foodstuffs that could not be solved for a long time. The population of the urban area of Harbin is 2.09 million. The suburbs of Harbin are equal to only the size of a medium-sized county in Heilongjiang Province. In the past, there were some leaders who thought that "a small suburb cannot solve a big problem." But when they made some practical investigations, they changed their ideas. They discovered that although the suburbs are small, they have great potential in developing animal husbandry. The problem is that in the past, suburban agriculture grasped only monoculture, the peasants raised only pigs, livestock departments grasped only the collective raising and the purchase and marketing of livestock and poultry products were monopolized by the state run commercial departments. All the above are the obstacles to the development of animal husbandry in city suburbs. Aimed at such circumstances, Harbin Municipality conducted readjustment and restructuring and thus a new situation has been created in developing animal husbandry in city suburbs.

Facts have proved that the key to developing animal husbandry in city suburbs is to straighten out the developing orientation of suburban agriculture. The CPC Central Committee has time and again pointed out that suburban agriculture must mainly solve the supply of vegetables, meat, eggs, milk, fruits and other nonstaple foodstuffs to cities. In other words, suburbs must be a base for producing nonstaple foodstuffs for cities. The fundamental reason why animal husbandry cannot be promoted in the suburbs of some cities at present is that they have not truly solved the principle problem. The initiative of a substantial number of our cadres in running animal husbandry is always not as high as their initiative in planting. In the suburbs of some cities, those commune owned industries eager to gain large profits usually placed the production of milk, meat, eggs, vegetables and other nonstaple foodstuffs in a secondary position. This incorrect practice must be changed. How to make the suburban agriculture serve the life of the people in cities much better and properly solve the living problems of more than a hundred million city civilians is a major event that has great political significance. Leading cadres in charge of urban work must attach full importance to the development of animal husbandry in city suburbs. If this work is grasped well, it is not only of advantage to cities but it also benefits the suburban peasants and increases their income so that they can become rich more speedily.

While developing animal husbandry in city suburbs, it is imperative to apply the policy of arousing the initiative of all aspects including the state, collective and individuals. In some cities, the state monopolizes the production and operation of livestock and poultry. As when it is necessary for expanding production, the state has to invest money, supply large amounts of feed and so on. Money is spent but the economic results are still not high. One of the important reasons why the suburbs of Harbin have developed so fast in animal husbandry is that while energetically supporting the specialized and key families in developing the production of milk and eggs, they have at the same time relied on the stock raising industrial and commercial enterprises which are represented in the main body of the state farm and together with large number of communes, teams and specialized families, they have organized and promoted the production and operation of animal husbandry and poultry products of the whole city. It seems that the way to achieve greater, faster, better and more economical results in developing animal husbandry in city suburbs is to support specialized and key families in raising pigs, cattle, sheep, poultry and so on. By applying this method, the state does not have to spend much money, whereas production can be swiftly developed and the peasants can become rich much faster.

REPORT ON EFFICIENT USE OF FARM WATER

HK070828 Beijing RENMIN RIBAO in Chinese 4 Dec 82 p 3

[Commentator's article: "Pay Serious Attention To Raising Efficiency in the Use of Water for Farm Purposes"]

[Text] Agriculture consumes most of the water in China. The water used in irrigation only occupies approximately 85 percent of the total quantity of water used in the whole country. It is anticipated that by the end of the century, the water used in agricultural irrigation will increase by 25 percent or more over the present amount. Where is this large amount of water to come from? There are two main ways. One is to develop resources and continue to construct a number of irrigation installations that need little investment and can bring about great economic results; and the other is to be economical by giving full scope to the potential of the existing water supply projects, economically and rationally use water and raise efficiency in the use of water for irrigation. From the situation of Zhanghe reservoir in Hubei Province, there is great potential in economizing on the use of water here, quick results have been achieved like "removing the husk and immediately seeing the rice."

The problem of economic results in water conservancy projects has aroused the attention of various localities in recent years. But there are some localities and units that calculate their agricultural output increase only after the construction of water conservancy works and calculate their income in the building of the project. Those projects that are in the final phase calculate the potential that can be tapped after the project has formed a complete set and place their hopes on adding more investment to raise the economic result and do not put their focus of attention on how to give full play to the management potentiality of the existing projects. As a matter of fact, the economic results of a water conservancy project cannot be judged by the big increase in agricultural production or the income of the project and its future prosperity. What is more important is that we must examine whether the water is properly managed and used. This is the most practical result that can possibly be achieved.

As far as most of the localities throughout the country are concerned, there is a popular problem of low efficiency in the use of water and a great wastage in water resources at present. The practices of using water but not managing it, "everybody sharing food from the same big pot" in the supply of water, all paying the same in water charges and irrational bearing of the charges will encourage wastage in the use of water and make the utilization ratio of water very low from the opening up of limited water resources. This is the reason why the economic results of many of the water conservancy projects have not been brought into full play.

Another reason for the low efficiency in the use of water is that we have not attached importance to the value of water. "Spending money like water" reflects the idea that regards water as a valueless thing. The water we use is gained through labor and investment. It is not merely the natural water that drops from the sky. Water is also a commodity. We must also work accounts in the use of water. Therefore, by reforming the method of "everybody sharing water from the same big bucket" through economic means, working out and perfecting the system of irrigation, rationally fixing water prices, directly connecting water with the economic interests of the people, whoever uses water should be responsible, the more he uses the more he should be charged; then the people who use water will try by every means to raise the efficiency in their use of water. Those who manage water will regard it a sum of wealth, attach importance to the maintenance of projects, pay attention to the dispatch of water supply and ensure the storage of water as much as possible under safe conditions.

At present, one work on the water conservancy fronts that has great significance is that we must use economic means to reform management in the use of water, establish and perfect a variety of responsible systems in water conservancy management according to local conditions, fully arouse the initiative of various respects in the management and proper use of water and promote the scientific use of water. This is also an important step for water conservancy work to create a new situation in the field of agricultural development. We hope that the water conservancy departments at various levels will energetically support this work.

FRESHWATER FISH OUTPUT REPORTED

HK270136 Beijing CHINA DAILY in English 27 Nov 82 p 3

[Special to CHINA DAILY: "Freshwater Fish Hits 1.5 Million Tons"]

[Text] China's catch of freshwater fish is expected to reach 1.5 million tons this year, 120,000 tons above target, according to the Aquatic Products Bureau of the Ministry of Agriculture, Animal Husbandry and Fisheries.

The State Council has given priority to the raising of freshwater fish and called on fisheries to aim for an annual four to five million tons by 1990.

In 1981, the catch was 1,370,000 tons, an increase of 30 percent over that of 1978. A total of three million hectares of water surface were used to raise fish in 1981, [figure indistinct] percent more than in 1978.

The state has invested 147.62 million yuan in 14 provinces and cities since 1977, setting up fish-raising centres.

These fish-raising centres can produce 45,000 tons of fish a year and have more than 365,333 hectares of water surface.

Some provinces and cities have also set up fish-raising centres of their own. Shandong Province has turned over more than 2,891 hectares to fisheries.

Yunnan Province has decided to invest an annual five million yuan on fisheries starting this year.

This year, 64 percent of 240,000 of Jiangsu Province's production brigades have started raising fish.

The number of families raising fish this year has reached 1,870,000. They are scattered in provinces and cities including Hunan, Hubei, Jiangxi, Guangdong, Jiangsu and Anhui.

RURAL ENTERPRISES RESPONSIBILITIES NOTED

OW201250 Beijing XINHUA Domestic Service in Chinese 1134 GMT 19 Nov 82

[Excerpts] Beijing, 19 Nov (XINHUA)--XINHUA reporter Shao Yongli reports: The national rural enterprise streamlining work forum ended in Beijing recently. The forum pointed out: "The quadrupling of total agricultural output value calls for rural enterprises to shoulder important responsibility."

Since the 3d Plenary Session of the 11th CPC Central Committee, enterprises run by communes, brigades and production teams in rural areas have been developing rapidly." China now has 1.33 million rural enterprises with 30 million staff members and workers. Last year their total output value reached 73.8 billion yuan. Over the past 3 years, it has increased by an average of 13 percent each year.

The leading comrades of rural enterprises in all provinces, municipalities and autonomous regions who attended the forum analyzed in detail the present situation and the status quo in rural enterprises. They pointed out: An unprecedented new situation has existed in the present rural areas. A new period of great developments is facing the rural economy. They believe that in order to reach the strategic goal proposed by the 12th CPC Congress and quadruple the total agricultural output value, it is necessary to rely on the peasants' enthusiasm and the popularization and dissemination of science and technology so as to raise the per-mu yields on the existing arable land.

All participants at the forum cited numerous facts to illustrate that the annual output value of rural enterprises may increase at a faster speed than that of farming and breeding. The total output value of China's rural enterprises from 1976 to 1981 increased by more than 100 percent.

NPC DEPUTIES REVIEW THRIVING RURAL ECONOMY

OW070215 Beijing XINHUA Domestic Service in Chinese 1740 GMT 3 Dec 82

[Excerpts] Beijing, 3 Dec (XINHUA)--Citing facts and personal experiences, many deputies attending the Fifth Session of the Fifth NPC have expressed their support for the profound scientific observation made by Premier Zhao Ziyang in his report on the Sixth 5-Year Plan that "the continual and all-round upsurge of agricultural production and prosperity in the rural areas are the important foundations for continuous improvement of the nation's economic and political situation."

Deputy Yu Jingzhong, an agronomist of the cotton seed farm of Siyang County, a county in northern Jiangsu constantly stricken by natural disasters, said: Xuzhou and Huaiyin are two prefectures notorious for their frequent natural onslaughts. But these two areas have displayed new vigor since the 3d Plenary Session of the 11th CPC Central Committee. In the 1950's, these two prefectures produced merely 4.5 billion jin of grain annually. The annual output rose to 8.8 billion in the 1970's. Last year the output soared to 13.3 billion jin. This year, the grain output of Huaiyin Prefecture alone reached 9.4 billion jin.

Deputy Meng Fulin, vice governor of Anhui, said: Although a quarter of Anhui's croplands were seriously waterlogged this year, the grain output still exceeded that of 1981, the previous peak year. In 1981, the province produced 36.3 billion jin of grain, topping that of 1978 by 22.68 percent. The average annual increase in the past several years has been 7.1 percent. The output of economic crops has increased even more rapidly. Compared with 1978, the output of cotton, oil-bearing crops, tobacco, jute and tea in 1981 increased 36, 205, 80, 89 and 24 percent, respectively. The peasants' living standards have substantially improved. In 1981, the per capita income of the province's rural population from collective distribution increased by 87 percent over 1978. Surveys of 10,000 families in 1981 show that the per capita consumption of foodgrain increased 26 percent, and that of meat, fish and eggs increased 28 percent over 1980; and the number of bicycles, sewing machines, radio sets and wristwatches owned by each family increased over 30 percent.

Deputy Li Linzhi, vice chairman of the Standing Committee of the Sichuan Provincial People's Congress, said: Sichuan has been reaping bumper grain harvests every year since 1979. The province's total grain yield in 1982 will reach approximately 74 billion jin, or over 6 percent higher than 1981. The province's agricultural structure has changed and production of commodity crops is developing. Last year the output of marketable agricultural and sideline products topped that of 1978 by 58 percent, and the amount of money earned by the peasants from selling agricultural and sideline products to urban residents was 1.5 times higher than 1978. The peasants' living standards have improved significantly. A survey of 125 production teams in 40 counties of the province shows that last year's per capita income in the rural areas was 221 yuan, which is almost 100 percent higher than the 127 yuan of 1978.

Owing to the adoption of the production responsibility system of fixing production quotas to individual households and improvement of production efficiency, a third of the manpower in the rural areas has become surplus manpower. Owing to higher output and income, the peasants have accumulated some money. Rural savings have now reached nearly 900 million yuan. The surplus manpower and financial resources are favorable factors for future agricultural development. Proper management and utilization of these resources will be highly beneficial in expediting agricultural modernization.

Deputy Zhan-bu-la-zha-bu, deputy chief of Hulun Buir League, said: The production situation on the Hulun Buir grassland has been improving every year, and so have the people's living conditions. This year, although the agricultural areas in the league have been hit by natural disasters, the total grain output has set a new record, and the peasants' per capita income has exceeded 300 yuan, topping that of last year by 60 percent. Despite unusual windstorms and snowstorms in the pastoral areas, the total number of livestock this year is still 18 percent higher than last year, and the livestock death rate has dropped to 8.2 percent from 10.4 percent in 1979. The commodity rate of livestock has doubled. The herdsmen are now happily buying additional Mongolian yurts. Many young people have married. Some families have sent their children to study in universities at their own expense.

CHANGES IN RURAL AREAS DISCUSSED

HK301446 Beijing JINGJI GUANLI in Chinese No 10, 15 Oct 82 pp 15-18

[Article by Zhang Zhongji [4545 6988 1015]: "Gratifying Changes in China's Countryside Over the Last 3 Years"--passages within slantlines denote boldface as published]

[Text] China has a population of 1 billion people, of which 800 million are in the countryside. In the readjustment of the national economy, what changes has the countryside witnessed? This is a question with which many people are concerned. Since the third plenary session, the localities have implemented the party's various rural policies and brought into play the socialist initiative of hundreds of millions of peasants. A lively and gratifying situation of prosperity in which the people live and work in peace and contentment has emerged in China's countryside. Such a situation manifests itself mainly as follows:

/1. The Production Relations Are Being Readjusted, the Peasants Are Doubling Their Efforts/

The production relations must comply with the development of the productive forces. This is an objective economic law independent of man's will. Since the third plenary session, the localities have restored and developed various forms of the responsibility system in agricultural production. This is, in essence, a major readjustment of rural production relations. It is in compliance with the needs of the masses and conforms to the historical trend. It has not only held firm to the socialist orientation of agriculture, but also adhered to the management methods which are suited to the requirements of the peasants. Therefore, in a short period of 2 to 3 years, the rural areas throughout the country have extensively established various forms of the production responsibility system such as assigning responsibilities at the sectional level, assigning responsibilities to specialized units, assigning responsibilities to each laborer (or each group) and linking remuneration to output, fixing output quotas on a household basis and assigning work to each household. Seventy percent of the production teams have implemented the system of fixing output quotas on a household basis or assigning work to each household. In Anhui, Guizhou, Gansu and Henan provinces, the production teams that have implemented the system of fixing output quotas on a household basis or assigning work to each household account for over 90 percent. Such a production responsibility system has, to varying degrees, broken away from the old formula inherent in the management of labor and overcome the shortcomings of issuing "confused orders" in production and of carrying out egalitarianism in distribution. It has directly linked the quantity and quality of labor of the peasants with their material interests, reflected in a relatively good manner the principle of to each according to one's labor, brought into play the peasants' initiative in production and opened up a broad road for further developing the productive forces. In the rural areas throughout the country, we can see that the peasants are doubling their efforts and are answering the party's call of "getting well-off through productive labor."

/2. Agriculture, Forestry, Animal Husbandry, Sideline Production and Fishery Are Flourishing, and Production Has Developed by a Large Margin/

China has a large population, and the problem of adequate grain production has not been solved. Undoubtedly, it is correct that we must at all times pay close attention to grain production. But in the past, some localities took grain as the key link regardless of soil conditions and without distinguishing whether it is a forest region, a pastorial area or a fish-breeding zone. They reclaimed land for grain production by destroying forests and grasslands and by building up dikes on lakes. Therefore, organisms' habits were out of balance and soil erosion was serious. As a result, not only could grain production not go up, the development of industrial crops and other trades was also restricted, and the state had to import more and more grain, cotton, sugar and oil every year. In the past years, in line with local conditions, the localities have paid attention to readjusting the structure of crop growing, carried out a diversified economy and tapped the potentials of natural resources and of labor power. Agriculture, forestry, animal husbandry, sideline production and fishery are flourishing, and production has developed by a large margin for successive years. From 1979 to 1981, the sown area of cereal crops was reduced by 85 million mu. But due to the raising of unit output, the total output of cereal crops in 1979 was 664 billion jin. The total output in the other 2 years also exceeded the highest level before 1978. Various industrial crops also increased consistently. In 1978, the output of cotton was 59.35 million piculs, an increase of 37 percent over 1978 [as printed]; the output of oil-bearing crops was 204.1 million piculs, an increase of 96 percent; the output of sugar crops was 720.56 million piculs, an increase of 51 percent; the output of tea leaves was 6.85 million piculs, an increase of 28 percent. In the development of crop growing, our diversified economy also developed rapidly. In 1981, the output value of forestry, animal husbandry, sideline production and fishery was approximately 61.7 billion yuan (calculated according to the fixed prices in 1970), an increase of 31.1 percent over 1978. Such a rapid and all-round development of China's rural economy is rare in history.

In the past few years, many localities have freed themselves from the narrow concept of small agriculture. They do not fix their eyes only on cultivated land; they also bring into play the superiority of the localities and make use of local resources. They have opened up the way for developing large agriculture. For instance, over the last 3 years, Jiangxi Province has reclaimed 9.78 million mu of uncultivated hilly land, wasteland and undeveloped water areas, of which 460,000 mu has been used for expanded cultivation of tea trees, mulberry trees and fruit trees, 8,176 million mu is for afforestation, 20,000 mu for herbage growing and 540,000 mu has been used for expanded marine product management. With other measures being adopted, the output value of the diversified economy of Jiangxi Province in 1981 was 4.09 billion yuan.

In the rural areas, there has been a further development in commune and brigade-run enterprises over the last 3 years. In 1981, the total income of China's commune and brigade-run enterprises was 67.04 billion yuan, a 55.4 percent increase over the 43.14 billion yuan of 1978. Building materials such as bricks, tiles, lime, sand and rocks produced by commune and brigade-run enterprises account for approximately 80 percent of the country's total output. Gold, raw coal and crude salt produced by commune and brigade-run enterprises account for 10-30 percent. Most knitted and embroidered handicrafts are produced by commune and brigade-run enterprises and by the peasants. In the 3 years from 1979 to 1981, the net profit of commune and brigade-run enterprises throughout the country was 33.57 billion yuan, of which 12.18 billion yuan was used to support poor production teams, for carrying out farmland capital construction and for the purchase of various kinds of agricultural machinery. In economy and technology, commune and brigade-run enterprises have become an important mainstay in realizing China's agricultural modernization. They are also an important component part of the collective economy which is indispensable in promoting economic prosperity in the countryside and improving the livelihood of the peasants.

/3. The Economic Results of Agriculture Have Remarkably Increased/

In the past 3 years, the implementation of various forms of the responsibility system has not only raised labor productivity in agriculture, but also reduced irrational expenses. Good.economic results have been achieved. In 1981, the total agricultural output value created by each agricultural laborer was 560 yuan on the average (calculated according to the fixed prices in 1970), 12.7 percent higher than that created in 1978; grain output increased from 2,075 jin to 2,118 jin (in 1979, it increased by 2,257 jin), an increase of 2.1 percent; cotton output increased from 14.76 jin to 19.34 jin, an increase of 31 percent; the output of pork, beef and mutton increased from 58.3 jin to 82.2 jin, an increase of 41 percent.

Various expenses in agriculture have dropped. This has changed the situation in which production increased but income remained the same. The proportion of various expenses in the total income of the basic accounting unit of the rural people's communes dropped from 34.9 percent in 1978 to 31.4 percent in 1981; the average net income provided by each 100 yuan rose from 187 yuan to 218 yuan, an increase of 16.6 percent. Particularly in the production teams that exercised the principle of fixing output quotas on a household basis and assigning work to each household, economic results were more marked. According to the investigation made by the Hunan Provincial Statistics Bureau on 34 production teams that exercised the principle of fixing output quotas on a household basis and assigning work to each household, in 1981 the total income of these production teams increased by 5.3 percent over the previous year, various expenses dropped by 19.5 percent, of which production cost dropped by 16 percent, management cost dropped by 39.5 percent and other costs by 58.4 percent.

/4. The Income of the Peasants Has Increased by a Large Margin/

Because production has developed and the state has raised the purchase prices of agricultural and sideline products and reduced or exempted part of rural taxation, the income of the peasants has increased for successive years.

According to the investigation which was made by selecting examples in respect to the income and expenses of the peasant families, the average net income of each person rose from 133.6 yuan in 1978 to 223.4 yuan in 1981, an increase of 67.2 percent. Well-to-do families in the countryside have increased in large numbers, and the number of families living in tight circumstances has fallen sharply. Of the total number of peasant households investigated, the number of peasant households with a per capita income of over 300 yuan rose from 2.4 percent in 1978 to 22.6 percent in 1981, and the number of peasant households with a per capita income of below 100 yuan dropped from 33.3 percent to 4.7 percent. Of the 12 areas and 241 counties in northwest Shandong, northwest Shaanxi, north Shaanxi, east Henan and west Hubei which were originally low-yielding and short of grain, the average income of each person obtained from the basic accounting unit in 49 counties has exceeded the average level of the whole country.

Viewed from the source of income of the peasants, the collective economy is the principal part of the rural economy. How collective production is carried out plays a decisive role in the peasants' income. In 1981, the number of peasant households with a per capita income of over 300 yuan, of which 218.3 yuan was obtained from the collective, was 6 times the number of peasant households with a per capita income of below 100 yuan, of which 36.4 yuan was obtained from the collective. Moreover, family sideline production is an important supplement to the collective economy. Since the implementation of the responsibility system, work efficiency has been remarkably raised, and more and more redundant labor force has been devoted to family handicraft, domestic animal and fowl breeding, hunting and other productive work. The peasants' income from family sideline production has rapidly increased. The per capita income from family sideline production rose from 35.8 yuan in 1978 to 84.5 yuan in 1981, an increase of 140 percent. The proportion of the per capita income in the total net income of the peasants rose from 26.8 percent in 1978 to 37.8 percent in 1981. At present, in the whole country there are already more than 2 million specialized and key households breeding domestic animals and fowls. They can make quick returns and create a high ratio of commodities with small investments and at low cost. They have opened up a new road for the development of the rural economy. Therefore, for the peasants to live in prosperity, it is important to expand the collective economy, to develop family sideline production, to bring into play the initiative of the collective and individuals and to pay attention to giving an impetus to the role of the peasants' technology in production and to the role of their specialized skills so as to develop in the orientation of specialization.

/5. There Has Been Marked Improvement in the Livelihood of the Peasants/

Following the increase of the peasants' income, their livelihood has remarkedly improved. An investigation by selecting similar examples with regard to the income and expenses of the peasant families shows the following:

In respect to eating: In the past, the peasants only thought of having enough to eat, but now they are beginning to pay attention to having nutritious food.

Flour and rice have increased in the food they eat. The increase of expenses on nonstaple food has been faster than the overall increase of the consumption of staple food, oil, meat, eggs and fowls. The average quantity of grain consumed by each person increased from 496 jin in 1978 to 512 jin in 1981. Of the above average quantity, the flour and rice consumed increased from 245 jin to 345 jin; the pork, beef, mutton and fowls consumed increased from 12.01 jin to 18.82 jin; and the oil consumed increased from 3.94 jin to 6.25 jin. Now the situation in which peasant families "did not have meat to entertain their guests nor oil to cook their dishes" is not often seen.

In respect to clothing: In the past, the peasants mainly wore cheap but durable clothes. Now they are beginning to pay attention to quality and styles. The average expenses of each person on clothing rose from 14.74 yuan in 1978 to 23.57 yuan in 1981. Besides ordinary piece goods and clothes, the peasants also buy synthetic fabrics such as medium- and long-fiber fabrics and polyester. The number of peasants who buy high-grade commodities such as woolen piece goods, silk piece goods, knitting wool, woolen sweaters and long woolen underwear has increased twofold over the last few years. Leather shoes are in vogue among young people in the countryside.

In respect to the use of consumer goods: the number of peasant families that can afford high-grade durable consumer goods such as "three turns and one sound" is increasing. ["Three turns" refers to bicycles, sewing machines and wristwatches; "one sound" refers to radios] in 1981, each 100 persons had 8.07 bicycles on average, an increase of 50.6 percent over 1978; 5.03 sewing machines, an increase of 45.8 percent; 10.01 wristwatches, an increase of 150 percent; 7.67 radios, an increase of 100 percent. Some peasant families are beginning to buy high-class consumer goods such as television sets, washing machines, recorders, electric fans and sofas. In the suburbs of Beijing and Shanghai, "television villages" have emerged, where every household has a television set.

In respect to living: In the past, the peasants were accustomed to building old-fashioned houses, but now they are beginning to get interested in [word indistinct] and bright houses which are artistic in design. The area of new houses built in the countryside over the last 3 years is 1.4 billion square meters, and on the whole the quality of these houses has improved. Nearly each and every family in some high-income production teams is either getting all the materials ready to build their new house or constructing their new house. By the end of 1981, each peasant had an average living area of 10.16 square meters, an increase of 25.4 percent over the 8.1 square meters in 1978. Of the new houses built in 1981, houses of the brick and wood-type accounted for 54.4 percent and houses of the reinforced concrete-type accounted for 2.9 percent. Nearly all the peasant houses newly built in the suburbs of Beijing and Shanghai are of these two types. In Tianjin, Hebei, Liaoning, Jiangsu, Zhejiang and Guangdong, houses of these two types account for 80 percent. New-type buildings suitable for the peasants have been built in some suburban areas.

Following the improvement of the livelihood of the peasants, surplus money and grain have increased. By the end of June 1982, the deposits of the peasants throughout the country was 19.49 billion yuan, an increase of more than 200 percent over 1978. If we consider the fact that the peasants have moved their savings accounts to the cities because they are not willing to show that they are rich, then the peasants' actual deposits are much more than the above figure. The characteristics of rural deposits in the past few years are that savings amounts keeps rising, new depositors have increased in large numbers and the proportion of long-term deposits is large. In respect to grain, it is quite common now that peasant families have several hundred jin or over a thousand jin of surplus grain.

/6. The Rural Market Is Thriving, Both Purchasing and Marketing Are Brisk/

Following the overall development of production in the rural areas, the commodity volume of agricultural and sideline products provided by the peasants and state farms has increased for successive years. In 1981, the total amount of the purchase of agricultural and sideline products by society was 95.5 billion yuan, an increase of 71.2 percent over the 55.8 billion yuan in 1978 (after deducting the prices of goods, the actual increase was 23.6 percent). Of the above percentage, the purchase volume of grain increased by 27 percent, the purchase volume of pork increased by 25.5 percent, the purchase volume of eggs increased by 76.6 percent and the purchase volume of cotton, sugar, flue-cured tobacco and tea leaves increased by over 20 percent. This has energetically supported the development of light industry and solved some problems in the people's livelihood. In addition, the commodities supplied to the rural areas by the state through various channels have increased daily. The total volume of retail sales of commodities in rural areas in 1981 was 132.4 billion yuan, an increase of 63.4 percent over 1978. If we consider the factor of the constant increase of the number of peasants going to towns and cities for the purchase of commodities, the actual growth rate is even higher. In the past few years, because the prices of agricultural and sideline products have been raised and the prices of some industrial products have been lowered, the price differences between industrial and agricultural products have narrowed, and the peasants have gotten more benefits from the exchange of commodities. From the sales of the same quantity of agricultural and sideline products, the peasants could get 26 percent more industrial products in 1981 than in 1978.

Since the implementation of the production responsibility system, the peasants have been very enthusiastic about making large investments in production. The total amount the communes and brigades and the peasants spent for the purchase of the means of agricultural production was 34.75 billion yuan in 1981, an increase of 18.3 percent over the 29.37 billion yuan in 1978. Of the increased percentage, the amount for the purchase of chemical fertilizer increased by 42.2 percent. The sales volume of small farm tools such as shovels, picks, hoes and sickles, which everyone has, has sharply increased. In the past few years, the number of well-to-do peasant households that have singly or jointly bought agricultural machinery such as tractors has increased twofold. Small farm implements which are cheap (not exceeding 1,000 yuan) and light (which can be moved by one or two persons) and which have manifold functions have been well received by the peasants.

In order to promote the exchanges of goods between town and countryside, the localities have energetically restored and developed free markets. In the whole country, there are now 43,000 free markets, in which the volume of business was

25.3 billion yuan in 1981, an increase of 19.3 percent over 1980. According to the statistics of 206 typical market places in the rural areas, the volume of business in the first half of this year increased by 23.4 percent over the corresponding period of last year. Some free markets are run on quite an impressive scale, and business in these free markets is brisk. For instance, in the county seat of Zhongxian County, Ningxia Autonomous Region, free markets are held on the 3d, 6th, 9th 13th, 16th, 19th, 23d, 26th and 29th of the month. There is a great variety of goods in the market place, and on market day people come in an endless stream, sometimes as many as 10,000. Besides the local people, there are also people from the southern mountainous regions of Ningxia and from neighboring provinces.

/7. The Peasants Are Unprecedentedly Energetic About Studying Science and Using Science/

In the past, the peasants "could not decide on what to do." They had no decision-making rights in carrying out their work. Everything was arranged by the cadres of the commune and brigade, and the peasants were not interested in scientific farming. Now they have "allied their hearts with production." They try every means to do a good job in farming, and their enthusiasm in studying agricultural scientific knowledge has been popularly raised. Science and technology have for the first time become much sought after in the rural areas. Wherever I went, people gathered around me, asking for advice. Several thousand communal associations for the popularization of science have been established in the rural areas throughout the country. In many localities, lectures, study classes and training courses on technology have been organized to train peasant technical cadres, who will be required to go to the production site to solve difficult problems on the spot, to pass on knowledge and to popularize the results of their research.

In order to master agricultural technology and culture and knowledge, many peasants take an active part in part-time study. In 1981, there were 411,000 peasants' part-time schools of various levels throughout the country, and the number of students studying in these schools was 10.77 million, of which the number of students in the secondary technical part-time schools was 1.08 million, the number of the students in the peasants' part-time middle schools was 634,000 and the number of the students in the peasants' part-time junior schools was 9.055 million.

/8. The Peasants' Cultural Life Is Beginning To Enliven/

Following the improvement of the material life in the countryside, the peasants are eager to enrich their cultural life and to change their past monotonous habit of "working with a hoe during the day and lying against a pillow at night." In order to meet the needs of the peasants, the departments concerned have energetically organized film projecting teams in the countryside and professional cultural troupes to perform in the rural areas. In 1981, each 10,000 persons in the rural areas throughout the country had an average of one commune and brigade-run film projecting team. Professional cultural troupes put on 520,000 performances in the countryside, and the audiences numbered as high as 520 million. In addition, the localities have formed, one after another, amateur cultural propaganda teams and established part-time study rooms and clubs. Cultural organizations and facilities such as simple cinemas and theaters, cultural centers, libraries and reading centers have been established in the market towns of some rural areas.

From the above we know that gratifying changes have really taken place in China's countryside over the last 3 years. Under such an excellent situation, we should also understand that we cannot yet completely change the backwardness of the rural economy and culture, which have existed for a long time, and that we will have many difficulties in our advance. For instance, the development of the rural economy is in disproportion. The peasants in some rural areas have not completely gotten rid of poverty. In some localities, the production responsibility system has been carried out with a rush. Meticulous attention has not been paid to their work, and there are still many problems with regard to cultivating farmland on a contract basis and to the handling of collective property. The circulation of commodities between town and countryside is not smooth enough. With regard to educational, cultural and public health undertakings, there is a large gap between town and countryside. In some rural areas, family planning is beyond control, and the growth rate of population is rising. Therefore, we must make persistent efforts in rural work so as to speed up the construction of our new socialist countryside.

BRIEFS

COTTON PURCHASES UP--Beijing, 17 Nov (XINHUA)--China's commercial departments purchased 2,015,500 tons of cotton by 10 November, 340,500 tons over the same 1981 period, according to a national cotton conference which opened here yesterday. The volume purchased represents 72 percent of the 1982 purchase quota. Last year, 2.9 million tons of cotton were sold to the state. The annual state purchase quotas were topped in the four provinces of Shandong, Hebei, Liaoning and Zhejiang. Shandong, Xinjiang, Hebei and Jiangxi all set records with this year's cotton output. The conference estimated that the total cotton output this year will be 350,000 tons more than last year. [Text] [Beijing XINHUA in English 1132 GMT 17 Nov 82 OW]

NEW RAPESEED PAYMENT PLAN--Beijing, 12 Nov (XINHUA)--A new payment plan for purchasing rapeseed will come into force in Sichuan, Anhui, Hunan, Jiangsu and other rapeseed-producing provinces in 1983. According to the new plan, 40 percent of the rapeseed, regardless of quantity, turned in to the state by the peasants, will be paid on the basis of the state monopoly prices and the remaining 60 percent on the basis of the fixed state prices for surplus quantities of rapeseed turned in to the state. This new payment plan was initiated to reduce the financial burden of the state which has, in the past few years, paid about 1.6 yuan for 1 jin of rapeseed purchased from the peasants but has sold them at about 0.8 yuan per jin. RECORD COTTON HARVEST--Beijing, 28 Nov (XINHUA)--China reaped a record cotton harvest of 3.35 million tons this year, 350,000 tons more than 1981, the Ministry of Agriculture, Animal Husbandry and Fishery announced. This is the fourth year running since 1979 which first saw increases in cotton output. The increased yields of 1,175,000 tons over the past 4 years equalled the total increased in the previous 28 years. Of the 15 provincial-level cotton producing areas across the country, Shandong which had the biggest increase reported a cotton harvest of 950,000 tons, 275,000 tons more than last year. The next came to Hebei which had an increase of 140,000 tons and Xinjiang which increased 35,000 tons. Jiangsu kept its previous high level of 550,000 tons this year. Shaanxi, Shanxi, Zhejiang and Jiangxi Provinces also registered some increases compared with 1981. [Text] [Beijing XINHUA in English 0707 GMT 28 Nov 82 OW]

CROP DISEASE ANTIBIOTIC--Beijing, 20 Nov (XINHUA)--An institute under the Chinese Academy of Agricultural Sciences has developed a new kind of antibiotic that is effective against several crop diseases and harmless to both humans and livestock. Antimycoin "120" has a powerful inhibitive or lethal effect on fungi of cucumber, wheat and flower powdery mildew and other diseases, according to the Institute of Pedology and Fertilizers. Experiments in communes of Beijing suburbs show that timely application of antimycoin "120" destroys more than 90 percent of diseases on contaminated cucumber plant, scientists of the institute said. On 17 experimental plots in Shandong and Hebei Provinces, antimycoin "120" eliminated 70 to 80 percent of wheat rust, a disease which cut wheat harvest by 30 to 50 percent in some areas. The institute also conducted an experiment to test whether the antimycoin is toxic. Intake by rabbits of antimycoin "120" over a 2-week period did not cause any abnormal function of heart, lungs, liver or other organs, the institute said. GUANGDONG RICE LEAFHOPPERS--In close coordination with each other, all departments in Guangdong Province did well in eliminating rice leafhoppers which damaged the late rice crop. From the end of September to the middle of October, 10 million my of late rice had rice leafhoppers and generally, each 100 grains had 5,000 to 6,000 and up to 20,000 to 30,000 rice leafhoppers, an increase of some 1,000 to several 1,000 percent on previous years. This seriously threatened late rice production. After discovering these rice leafhoppers, all areas immediately took urgent measures to eliminate them. On 27 September, the general office of the provincial government issued an urgent telegraphic circular to all places on quickly wiping out rice leafhoppers damaging late rice. As a result of the efforts made by all areas, large areas of insect pests were quickly put under control. According to statistics compiled by relevant departments, only 10 percent of the 10 million mu where there were insect pests suffered varying degrees of loss. COMMUNE CONGRESS TERM--Beijing, 19 Nov (XINHUA)--The 25th session of the 5th NPC Standing Committee has decided that the present term of the people's congresses at the commune and town level directly elected by voters, an experiment which started in the latter half of 1979 and ended at the end of 1981, is extended to the end of 1983. ANHUI PROVINCE GATHERS RECORD 1982 HARVEST

OW030938 Beijing XINHUA in English 0804 GMT 3 Dec 82

[Text] Hefei, 3 Dec (XINHUA)--Anhui, the first province in China to institute the responsibility system in agriculture, gathered a record harvest this year despite floods and waterlogging caused by heavy summer rainfall, the provincial agricultural department reported.

Grain output totalled 18.5 million tons, 350,000 tons more than the peak year of 1981, the department said. The figure represents an increase of 3.5 million tons over 1977, the year before the system went into effect.

Output of oil-bearing crops was 1.25 million tons, 26 percent more than 1981 and 4.3 times that of 1977, the department said. Records were also set in output in tea, flue-cured tobacco, fruits, freshwater fish, and in the number of draught animals and poultry.

The good harvest is due largely to popularization of new agrotechniques and good crop varieties, soil improvement and increased use of fertilizer, the department said. Waterlogged fields were promptly drained and replanted. This year, the province planted hybrid rice varieties on 133,000 hectares, a 28.6 percent increase over last year. Fine varieties of seeds were used on most of the wheat and rice fields.

The responsibility system, whereby peasant families farm the collectively owned land under contracts, has enhanced the initiative of the peasants. This is because peasant families are now given more right in farm management and their income depends on the harvests from their contracted land.

The department estimates that per capita income for Anhui's peasants will average 240 yuan this year, 40 yuan more than last and 140 percent above 1977. Of Anhui's 70 counties, 24 expect an average per capita income exceeding 300 yuan.

By 21 November, the department said, peasants had sold nearly 3.5 million tons of grain to the state, 850,000 tons more than in the same 1981 period. Grain sold by the peasants to the state now accounts for 26 percent of the total annual grain harvest, compared with the previous 19.3 percent.

Grain storage capacity has been expanded by one-fifth in the past four years, but is proving to be insufficient. Large numbers of makeshift bins have been put up by government grain stores and peasant families to contain the newly harvested crops.

Peasants in flood-hit Chuxian Prefecture--the first to institute the system in Anhui--will sell 750,000 tons of grain to the state this year: 60,000 tons above last year, the department said. This is an average of 259 kilograms per capita, ranking first in the province.

NPC DELEGATE ON PROVINCE'S HARVEST

OW031128 Beijing XINHUA in English 1109 GMT 3 Dec 82

[Text] Beijing, 3 Dec (XINHUA)--East China's Anhui Province is expected to bring in another bumper harvest this year despite bad weather, reported Vice Governor Meng Fulin, who is here attenting the National People's Congress.

This will be the fourth good year since the province instituted the responsibility system in agricultural production in ouom.

In an interview with XINHUA today, Meng Fulin recalled that more than one-sixth of the province's croplands suffered from natural disasters in 12 of the 33 post-liberation years, each time causing an average loss of 1.15 million tons of grain. But this year, grain output will surpass the record 1981 harvest, although a quarter of the croplands were affected by serious waterlogging.

"This shows the advantage of the production responsibility system," he said.

Anhui was one of the first provinces in China to introduce the system. "The peasants like it, because it gives them greater freedom to arrange their time and work and encourages them to work harder and earn more," the vice governor said.

In 1981, Anhui's grain output reached 18.15 million tons, 22.68 percent more than that of 1978, he said. The output of industrial crops increased even faster in that period, when the growth rates for cotton, oil-bearing crops, cured tobacco, bast fiber crops and tea ranged from 24 percent to 205 percent. Forestry, stock breeding, sideline production and fishery also developed rapidly.

Meng Fulin said growing output has resulted in more income for the peasants. The per capita income of Anhui Province's rural population derived from the collective last year was 87 percent higher than in 1978.

CIRCULAR ISSUED ON VEGETABLE SUPPLY

OW170637 Hefei Anhui Provincial Service in Mandarin 1100 GMT 15 Nov 82

[Excerpts] According to an ANHUI RIBAO report, the provincial vegetable production and marketing office recently issued a circular calling on the various prefectures and municipalities to seriously implement Comrade Chen Yun's directive, do a good job in the production, supply and marketing of autumn vegetables and take effective measures to ensure plentiful vegetable supplies during the coming winter-spring season.

The circular proposes:

1. Immediately organize agricultural scientific personnel to closely inspect commune and brigade vegetable fields plot by plot in coordination with local agricultural scientific stations.

2. Do a good job in the production and field management of overwintering vegetables. Water oats, spinach, lettuce and garlic are major varieties of vegetables for next year's spring vegetable market. Overwintering vegetables must be grown in the 70,000 mu of vegetable plots--a project that has been approved this year. Efforts must be made to strengthen field management and increase production and income.

3. Do a good job in harvesting, supplying, storing and perserving autumn vegetables. All units, armymen and people must be encouraged to grow overwintering vegetables. Those production teams who specialize in growing vegetables must not sell their vegetables at a high price on the local market before they have fulfilled their contract targets. The retail prices for various major autumn and winter vegetables must remain stable as last year's.

4. Allow for unforeseen circumstances in planning vegetable supplies for the coming winter-spring season.

SHORTAGES OF SOME FOODS LEAD TO LINES

OW090601 Beijing XINHUA Domestic Service in Chinese 0020 GMT 1 Dec 82

[Newsletter by XINHUA reporter Chen Xianxin: "What the Masses Urgently Need Must Be Promptly Resolved--A Situation Reflected by the Sale of Dezhou Braised Chickens in Beijing"]

[Excerpts] Beijing, 1 Dec (XINHUA)--Toward the end of last year, a store selling Shandong braised chickens was opened in Beijing's Xidan District to the great delight of the people in Beijing. The problem was: The demand far exceeded the daily supply of 400 to 600 chickens because of the limited supply of raw chickens and limited processing capabilities, so the customers had to line up in front of the shop early in the morning in order to buy a chicken. The store's next-door neighbor, the Heavenly Fortune, is another store selling soysauce-preserved pigs feet, a dish of typical Beijing flavor. Like its neighbor, its supply could not meet the demand, so there were always two long lines of people in front of these two stores.

Similar long lines can also be seen in other places, such as the shop selling cold noodles at the northern end of Fuyou Street. The lines in front of the store selling vegetarian food and the Donglaishun Restaurant on Wangfujiang Street are even longer--and it has been like this for years. In many other places, the scenes of people standing in line to buy beancurd and bean products and to pick up milk are common.

These days, when the weather is getting colder and colder, can anything be done so that people do not have to stand in long lines on the street in the cold? For this reason, this reporter recently visited certain departments concerned and interviewed some urban residents. They maintain that the Beijing authorities have performed many good services for the people in recent years, but that the handling of certain other urgent problems is still too slow. They also put forward the following suggestions:

1. The authorities concerned must have a sense of urgency. After a central leading comrade became aware of the long lines in front of the chicken store, he kept the problem in mind. First he instructed the Beijing Municipal Government to solve the problem, and then instructed the Ministry of Commerce to handle it. The problem was finally resolved after the China Food Company of the Ministry of Commerce held a meeting to discuss a solution to the problem with other

authorities concerned in Beijing. If other authorities concerned in Beijing also cared for the interests of the people like the leading comrade of the central authorities did, other problems could certainly be solved much faster.

2. Practical actions have to be taken. In certain cases, the problem of standing in line may not be very easy to solve; but many other problems can be solved with some effort. For example, the solution to the problem of picking up milk is simply a matter of setting up additional points and lengthening the service hours. If there are not enough people to do the job, as some people have claimed, there is currently a large number of young people waiting for employment. Why can these young people not be hired as temporary or contract workers so that this problem can be settled?

3. The leading authorities must dare to make decisions. The reason why certain urgent problems have remained unresolved is not because they cannot be solved, nor is it because the people at the basic-level units are not willing to solve them; it is because of the fear of the responsible departments to make decisions, and the reason for their fear of making decisions lies in their fear of being held responsible. So, whenever there is a problem that needs their attention, they glance left and right for fear that somebody might have been offended or neglected by their actions. Consequently, they are hardly capable of a decision. These days the problem of eating a meal in Xidan District is a serious one since five restaurants of the Xidan market have suspended operations after the Tangshan earthquake in 1976 and their buildings are considered unsafe. To discuss relocation and other problems, 12 meetings have already been held this year by the responsible department and various other units concerned, but a final decision has yet to be made. The meal problem still remains today.

'XINHUA' REPORT ON INDISCRIMINATE TREE-FELLING

OW240613 Beijing XINHUA Domestic Service in Chinese 1134 GMT 23 Nov 82

[Text] Beijing, 23 Nov (XINHUA)--XINHUA reporter Cui Lisha has learned from the Ministry of Forestry that, after a month of vigorous effort, various provinces, municipalities and autonomous regions have achieved initial results in implementing an "urgent directive calling for stopping indiscriminate tree-felling" issued by the CPC Central Committee and the State Council. In areas where forests are rather seriously damaged, the evil practice of indiscriminate tree-felling has been checked to a certain extent.

The CPC Central Committee and the State Council issued the "urgent directive calling for stopping indiscriminate tree-felling" on 20 October. Paying close attention to the directive, various provincial, municipal and autonomous regional party committees promptly took effective measures to implement it. The party committees and governments of eight provinces and autonomous regions--Nei Monggol, Shanxi, Shaanxi, Guangxi, Guizhou, Xinjiang, Heilongjiang and Qinghai--immediately called meetings to discuss and make arrangements for implementing the "urgent directive." The party committees and governments of 17 provinces and autonomous regions held telephone meetings and issued specific circulars or instructions calling for implementing the "urgent directive" according to local conditions. First secretary Huo Shilian of the Shanxi Provincial CPC Committee personally presided over a meeting to discuss the question of how to implement the "urgent directive." He said: Implementing the "urgent directive" is not only holding meetings; what is important is to carry it out practically. On 8 November, the Shanxi Provincial People's Government called together cadres of the counties where forests had been seriously damaged to discuss concrete measures to stop indiscriminate tree-felling.

Following the example set by the central disciplinary commission in sending work teams to assist provinces and autonomous regions in handling major cases of denudation, various provinces, municipalities and autonomous regions have dispatched work teams composed of personnel from public security, procuratorial and judicial departments to areas where forests have been seriously damaged. Vigorously publicizing the "urgent directive," those work teams have assisted local authorities in grasping what is practical, dealing with hard cases and investigating cases of denudation. They have handled a number of cases in which leading cadres took the lead in stripping lands of forest as well as cases of a vicious character.

Recently, the Jian Prefectural Party Committee in Jiangxi Province severely dealt with the case of Liu Zhongdao, Standing Committee member of the Anfu County Party Committee and deputy head of the county, who formed a partnership to purchase green hills and illegally transport lumber. The prefectural party committee has punished Liu Zhongdao by removing him from his post in the party and has proposed to the local government to dismiss him from his post as deputy county head. Liu Dulian of Hecheng town, Qingtian County, Zhejiang Province, was sentenced to death and immediately executed for illegally felling trees and killing a forest ranger.

The CPC Central Committee and the State Council have assigned responsibility for the protection of forests to the county party committees and people's governments. As a result, some leading cadres at the county level, who felt a lack of authority to stop indiscriminate tree-felling in the past, have been able to stand erect, and those who used to wink at cases of denudation have been shaken up.

They have now swung into action. According to incomplete statistics compiled by Zhejiang Province, prefectures and counties in the province have sent out 150 work teams with the participation of nearly 1,000 cadres at various levels. Various prefectures and counties in Hunan Province have released more than 6,700 personnel from other work to sort out cases of denudation. Those personnel have discovered, through investigation, that more than 8,400 cubic meters of lumber were illegally felled and transported, and they have imposed fines totaling over 31,000 yuan. They have dealt with 83 persons who illegally felled trees and have had 73 of them arrested. Ten production teams of the Niuweishan and Xiboling brigades under the Yangshulin commune in Nongan County, Jilin Province, had, since 1979, seized more than 1,350 mu of state-owned forests, destroyed forest rangers' houses, folled their wells and forcibly harvested over 300 mu of crops planted by forest farms. These cases remained unsolved for several years. After the "urgent directive" was issued, the county party committee immediately organized a work team to thoroughly investigate these cases. This work team made a decision on the handling of these cases in 9 days.

While implementing the "urgent directive," all localities have paid attention to strengthening forest administration, frozen the felling of trees beyond the state plan and closed free lumber markets. Sichuan and Henan Provinces have closed 124 such markets in their counties. Lishui, Jinhua, Wenzhou and other prefectures (municipalities) in Zhejiang Province, in 10 days, closed over 140 free lumber markets and discovered a number of cases of indiscriminate tree-felling and profiteering by buying lumber cheap and selling it dear. The Guizhou Provincial Party Committee and people's government have recently decided to institute a system on 1 December under which trees are to be felled throughout the province only by permit. Those who cut trees without permission from departments in charge of forestry will be dealt with as indiscriminate tree-fellers.

According to information provided by the Ministry of Forestry, although tremendous achievements have been made in implementing the "urgent directive" of the CPC Central Committee and the State Council, leading cadres in a few localities have still underestimated the seriousness of indiscriminate tree-felling, have no clear idea of major cases of denudation and have only issued general calls in leading the work in this regard. Cases of indiscriminate tree-felling have continued and even such serious cases as jointly attacking or beating up work team members trying to stop indiscriminate tree-felling have taken place in some individual localities after the central authorities issued the "urgent directive." Even in places where the "urgent directive" has been better implemented, the task of investigating and handling cases of denudation is still arduous. This calls for all localities to continue to make vigorous efforts to effectively implement the "urgent directive."

BROADCASTS DISSEMINATE AGRICULTURAL EXPERTISE

OW011009 Beijing XINHUA in English 0810 GMT 1 Dec 82

[Text] Beijing, 1 Dec (XINHUA)--Crop yields and agricultural expertise have been boosted through popular science loudspeaker broadcasts in Beijing's rural suburbs, according to Jia Yongling, member of Da Xing County's broadcasting station.

A loudspeaker network connected with transmission stations in production brigades throughout Beijing's nine surrounding counties has been established by the broadcasting stations set up by the county governments. Almost all the villages in the counties have loudspeakers fixed on poles, making their broadcasts audible across wide areas. Programs are aired one hour in the morning and another hour in the evening, with agroscience broadcasts two or three times each week, Jia Yongling said.

The Da Xing station alone has broadcast 408 programs contributed by experienced peasants and experts. The programs have covered subjects such as planting, fertilizing, irrigation and management of wheat and maize, the main crops of north China, cultivation of watermelon and peanuts, profitable sideline crops, pig and chicken raising and the use of marsh gas and solar energy. The broadcasts give advice on local climate, soil and economic value, Jia Yongling said.

The stations often receive requests for repetition, further details and other information. Some communes have recorded the programs and arranged workshop sessions, he said.

A typical example is that of a 50-year-old peasant Xie Tian of Caiyu Commune. However a program of scientific farming is on the whole family of seven hushed up. Even kids learned to keep quiet. Sometimes, there is a bit of controversy among the family members over the methods. But Xie Tian said: "I am willing to follow the broadcasted instructions. I will be the head of the experimental group." This year he reaped over ten tons per hectare on the land he tilled under the responsibility system.

RURAL CADRES' AGRICULTURAL STUDY--Beijing 24 Nov (XINHUA)--More than 5,000 rural cadres from all over China have attended training classes to study agricultural sciences since 1979, and 900 are now studying. This was disclosed by the Educational Department of the Ministry of Agriculture, Animal Husbandry and Fishery. The training classes, 4-1/2 months each term, started in September 1979. The participants study 12 to 15 subjects during the training period, including agroeconomics, agronomy, veterinary science and farm machinery. The participants, including provincial, prefectural and county-level cadres, average 50 years old. Most of them took part in the revolution before liberation in 1949. They have rich experiences but still have to acquire more systematic scientific knowledge. The Party Central Committee has urged cadres in charge of rural work to study agricultural sciences time and again since December 1978. [Text] [Beijing XINHUA in English 0838 GMT 24 Nov 82 OW]

BRIEFS

SUGARBEET PRODUCTION--Since 1980, sugarbeet production in Gansu Province has greatly increased each year. The province's areas sown with sugarbeets this year have reached some 98,000 mu and are some 200 percent higher than in 1979. The amount of sugarbeets procured by the province this year is approximately 130,000 tons. The province has quadrupled its output of sugarbeets within 3 years. Since 1979, the provincial people's government has reiterated its policy that 10 jin of sugarbeets is equal to 1 jin of grain for procurement and has raised the sugarbeet procurement price from 3 fen per jin to 3.9 fen per jin. After this policy was followed, commune members' enthusiasm in cultivating sugarbeets was gradually aroused. [HK071503 Lanzhou Gansu Provincial Service in Mandarin 0420 GMT 4 Dec 82 HK]

FORESTY MEETING--From 3 to 7 November, the Ministry of Forestry held an appraisal meeting in Tianshui, Gansu Province. The meeting held that the method of cultivating forests on the Xiaolongshan Mountain in Tianshui can be applied and popularized in the northern part of the country. This scientific research was conducted by the Research Institute of Forestry of the Academy of Forestry Sciences of China, the Provincial Research Institute of Forestry Sciences and the Xiaolongshan Forestry Experimental General Farm in Tianshui Prefecture for over 20 years. Experts, professors and engineers attended the meeting. [HK171538 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 15 Nov 82 HK]

WATER, SOIL CONSERVATION--The Gansu provincial conference on water and soil conservation ended yesterday. The conference reiterated the principle that whoever undertakes and controls water and soil conservation benefits. The conference also decided that the Dingxi, Jingchuan, Qinan and Ning counties are the key counties where water and soil conservation is undertaken and controlled. The conference pointed out that the province has achieved good results in bringing soil erosion under control. However, the cadres and commune members in a very large number of communes and brigades do not now deeply understand the relations between water and soil conservation and rebuilding ecological balance and human subsistence. These communes and brigades often bring soil erosion under control on the one hand and sabotage water and soil conservation on the other hand so as to damage the ecological environment and increase natural disasters. To improve this situation as quickly as possible, the conference demanded that all places take resolute measures to curb the damage to forests and grass and the sabotage of water and soil conservation. They must vigorously plant trees, grow grass and step up farmland capital construction. At the conference, Vice Governor Zhang Jiangang made a report, entitled: "It is necessary to seriously implement the spirit of the national conference on water and soil conservation work and strive to create a new situation in water and soil conservation work in our province. [HK231341 Lanzhou Gansu Provincial Service in Mandarin 1125 GMT 19 Nov 82 HK]

TREE PLANTING--Delegates to the Gansu provincial meeting of model workers helped plant trees and clean streets and paths in various places in Lanzhou on 10 November. Also participating were provincial CPC committee first secretary Feng Jixin, Governor Li Dengying, and Gansu military district Commander Li Bin. [HK110615 Lanzhou Gansu Provincial Service in Mandarin 0420 GMT 11 Nov 82]

GRAIN PRODUCTION FORUM--The forum on the development of grain production in the Hexi area held by the Shaanxi Provincial People's Government [as printed], concluded in Zhangye yesterday. Provincial agricultural committee chairman (Li Zhong) made a report, entitled "It is essential to seriously implement the spirit of the 12th Party Congress and to speed up the development of the Hexi commodity grain base." Governor Li Dengying and provincial CPC committee advisor (Yang Shouren) attended and spoke. In his speech, Li Dengying said that speeding up the building of the Hexi commodity grain base is a major task which has a bearing on the 3 million people in the Hexi area as well as on agriculture and the national economy throughout the province. He said that a very large area in the center of the province is not self-sufficient in grain. To change this situation of hardship, we must mainly rely on the development of the Hexi commodity grain base. In so doing, we must tap potential and reclaim wasteland. The Hexi commodity grain base must regard grain production as the main work. While grasping grain production well, it must vigorously develop diversification. NPC DEPUTIES NOTE ECONOMIC BOOM

HK270601 Beijing XINHUA Domestic Service in Chinese 0333 GMT 27 Nov 82

[Text] Beijing, 27 Nov (XINHUA)--Guangdong Province has reaped a great bumper harvest in agriculture this year. Total grain output is expected to top last year's by more than 10 percent and to set a new record. This was said to our reporter by Guangdong deputies attending the Fifth Session of the Fifth NPC.

Harvesting of the late rice is now almost completed. The province's total grain production is expected to show an increase of about 4 billion jin over last year.

While the province has been achieving bumper agricultural harvests, its industry has also developed relatively fast. According to material provided by responsible persons of the province's industrial departments, total value of output from January to October increased by 9.31 percent over the same period last year. This included an increase of 10.53 percent in light industry and 7 percent in heavy industry. Total industrial output value over the whole year is expected to top last year by about 8 percent.

The development of production has provided relatively ample commodities for the urban and rural markets, where supplies are becoming more and more abundant. In the first 10 months of the year, the total retail sales volume of social commodities was 17 percent greater than in the same period last year. This included a rise of 16.9 percent in retail sales volume of production materials, which are mainly bought by the peasants and collective units.

There has been new growth in the incomes of the urban and rural people. This is shown not only in the big increase in volume of commodity retail sales but also in the rise in urban and rural savings deposits. According to statistics of end-October, individual urban and rural savings deposits in the province had reached 5.98 billion yuan, a rise of over 30 percent compared with the same time last year.

At the same time, the situation in the province's expenditures and revenue is very good. Revenue has increased by 4.5 percent compared with the same period last year.

In the wake of the all-round upsurge in the economy, plus the measures taken by the government, prices in the provinces have tended to be stable this year, with the price increase index being lower than last year. There are ample vegetable supplies in the urban areas, and the general level of retail prices has fallen. Meat supplies are also greater than last year, and the prices of industrial products have been stable, with a tendency to fall.

BUMPER AGRICULTURAL HARVEST REPORTED

HK300241 Guangzhou Guangdong Provincial Service in Mandarin 2350 GMT 29 Nov 82

[Text] This year the rural areas of Guangdong have seriously implemented various types of production responsibility system and vigorously popularized scientific cultivation. As a result the province has scored an all-round bumper harvest. According to investigations conducted by the provincial statistics bureau, total grain output is expected to reach 37.5 billion jin, an increase of 4.6 billion jin over last year and of 1.5 billion jin over the previous record, set in 1980. This was achieved despite a reduction of 1 million mu in the sown area. Total grain output and average yield and the total output of sugarcane, peanuts, soybeans and tobacco have all set new records. The total value of agricultural output over the whole year is 12.74 billion yuan, an increase of 721 million yuan--6 percent--over last year. This is a rate not seen for many years.

At present the rural areas of the province present a scene of prosperity and the peasants are in high spirit. This situation is one of the best since liberation. There are four main special features of this year's all-round bumper harvests:

1. Increased output of grain was gained from all three harvests, spring, summer and autumn, and large, balanced increases were achieved over wide areas on the plains, in the hills and mountains, and on high and low-yielding land. All 13 prefectures, administrative regions and municipalities increased production.

2. Apart from hemp and bluish dogbane, relatively great increases were recorded in the main industrial crops.

3. The bumper harvest of grain and industrial crops has promoted the development of animal husbandry.

4. In the wake of increased agricultural output and income, the peasants' incomes have increased everywhere. The average net income per peasant may well reach 380 yuan, an increase of 55 yuan--16.9 percent--over last year.

AUTUMN GRAIN PROCUREMENT DISCUSSED

HK031100 Guangzhou Guangdong Provincial Service in Mandarin 1000 GMT 2 Dec 82

[Text] Recently, the provincial people's government issued a circular on seriously doing a good job of procuring and storing autumn grain. Various areas are called on to strive to fulfill and overfulfill the general grain procurement plan for the whole year.

The circular said that our province achieved bumper harvests of early and late crops this year. This will play a positive role in enlivening the urban and rural markets, stabilizing prices and realizing the objectives of struggle put forth at the 12th CPC National Congress.

The demands of the circular are:

1. We must insist on upholding the principle of contracting for grain and making a unified assessment every 3 years. The fulfillment of the state general grain procurement plans to which production teams and peasant households are committed, must be guaranteed. This year, except for a small number of teams and households seriously affected by natural calamities in some areas, which have been granted reductions or exemptions in grain sales in an assessment based on the relevant policy, no team or household can fail to fulfill procurement plans in time. Those for whom the fulfillment of procurement quotas was deferred last year due to natural disasters or whose quotas have still not been fulfilled after reduction or remission last year due to natural disasters, must fulfill their quotas. State farms, including overseas Chinese farms, which have contracted for state grain procurement plans must guarantee their fulfillment.

2. We must properly take care of the fulfillment of extra grain procurement quotas and the organization of grain storage. Extra grain procurement quotas are a component of the state procurement plan. Fulfillment of extra grain procurement quotas is the peasants' obligation to the state that should be carried out.

Concerning a small number of areas where work for the fulfillment of extra grain procurement quotas has not been put on a solid basis, we must place it on a firm basis from team to team and household to household and pay close attention to organizing grain storage. The aim is to have extra grain procurement quotas fulfilled.

3. We must energetically procure fine-quality grain and insure the fulfillment of export plans. Where procurement contracts have been signed with production teams and peasant households and the required chemical fertilizers have been provided, production teams and peasant households must fulfill procurement plans based on contracts. Production teams and households which have fulfilled annual general grain procurement plans for early crops and which have grain ration problems after selling fine-quality grain from late crops may have common-grade in exchange where common-grade grain is available in the state granary. After fulfilling plans based on contracts, those production teams and households which still have fine-quality grain left may sell it to the state at negotiated prices.

The circular stressed that governments at all levels cannot slacken in any way their vigilance in regard to the grain problem. Still less can they use grain freely after a bumper harvest is achieved in one year. They must direct serious and proper efforts to autumn grain procurement. Before the end of the year, they must complete the task of procuring and storing grain.

FORESTRY MINISTER YANG ZHONG VISITS HAINAN

HK110658 Haikou Hainan Island Service in Mandarin 0330 GMT 11 Nov 82

[Text] Minister of Forestry Yang Zhong inspected forestry work in Hainan from 2 to 9 November. He made important speeches on how to implement the Central Committee and State Council urgent instructions on curbing indiscriminate lumbering and speed up forestry development in Hainan.

Comrade Yang Zhong conveyed to responsible comrades of the regional CPC committee and commissioner's office and the autonomous prefectural government the important speeches of Premier Zhao Ziyang and leading comrades concerned of the State Council. He suggested holding meetings of county CPC committee secretaries, county heads, and principal responsible persons of the agricultural reclamation system, the PLA, and the public security departments, procuratorates and courts to seriously study the urgent instructions of the Central Committee and State Council and the speeches of Zhao Ziyang and other leading comrades, to unify thinking and adopt effective measures to resolutely curb the bad trend of indiscriminate lumbering.

During his inspection, Comrade Yang Zhong went to some commune and brigade forest farms in Qionghai and Wanning counties, the (Shangshan) State Forest Farm, and the (Tianfangling) Tropical Forest Reserve. He met (Xiao Jiahe), CYL branch secretary of (Lelai) brigade of (Lelai) commune in Wanning County, a regional standard-bearer in forestry production.

Comrade Yang Zhong gave quite a high evaluation of the region's forestry technique, organizational forms and achievements. He said: "Hainan Island has excellent conditions for developing forestry production. It also has experience in this respect. To promote forestry protection and afforestation represents an important way for the Hainan people to get rich through hard work. With forestry work promoted, Hainan will become a treasure island worthy of the name.

CSO: 4007/67

BRIEFS

HAINAN PEASANTS' INCOME INCREASES--The Hainan Statistical Bureau has conducted a sample investigation of the economy of 120 households of commune members in Wenchang, Qionghai, Dingan and Dan counties. In the third quarter of this year, the average monthly income of each household was 249.3 yuan and the per capita monthly income was 41.8 yuan, which was 16.9 yuan more than in the second quarter. These are the highest records in the region since liberation. In the third quarter, each of these 120 households spent 446.4 yuan in cash on commodities, an increase of 37.4 percent over the second quarter, and 152.5 yuan on the means of production, an increase of approximately 100 percent over the second quarter. [Haikou Hainan Island Service in Mandarin 0330 GMT 8 Nov 82 HK]

HAINAN BUMPER AGRICULTURAL HARVEST--Compared with last year, in the Hainan administrative region this year, grain production has increased by some 190 million jin, an increase of 8 percent; oil-bearing crop production has increased by 20.97 million jin, an increase of 53.7 percent; sugarcane production has increased by 700,000 tons, an increase of 70 percent; production of dry rubber pieces has increased by 1,171 tons, an increase of 12.2 percent; pepper production has increased by 7,360 dan, an increase of 29 percent; pineapple production has increased by 200,000 dan, an increase of 80 percent; and cashew nut production has increased by 6,810 dan, an increase of some 100 percent. The region has a large number of communes in which the average per capita income is over 500 yuan; and a large number of brigades in which the average per capita income is over 1,000 yuan. Some peasant households each annually sell over 20,00 [as printed] jin of grain to the state. According to incomplete statistics, the whole region has trained some 300,000 peasant technicians this year. [HK071505 Haikou Hainan Island Service in Mandarin 0330 GMT 4 Dec 82 HK]

WATER CONSERVATION FUNDS--The Guangdong Provincial People's Government recently decided to allocate 4.46 million yuan of additional special funds to support disaster stricken areas to quickly repair water conservation projects. These areas include Hainan Administrative Region and Zhanjiang Prefecture, which were hit by typhoons Nos 17 and 21, and Shaoguan, Zhaoqing and Huiyang Prefectures, which were flooded this year. BUMPER HARVESTS IN AGRICULTURE REPORTED

HK030807 Beijing ZHONGGUO XINWEN SHE in Chinese 0715 GMT 1 Dec 82

["Guangxi Reaps an All-Round Bumper Harvest in Agriculture"--ZHONGGUO XINWEN SHE headline]

[Text] Nanning, 1 Dec (ZHONGGUO XINWEN SHE)--The Guangxi Zhuang Nationality Autonomous Region reaped an over [word indistinct] bumper harvest in agriculture this year. According to the latest statistics, grain output has totaled 25.5 billion jin, an increase of 2.5 billion jin or over 10 percent over that of last year. The total output of industrial crops and meat as compared with that of last year is as follows: an estimated increase of 28 percent in sugarcane; an increase of 23 percent in fruits; a relatively big increase in tea, silkworms, tobacco, ramie, rape seed and cassave; and an increase of 11.2 percent in pork, beef and mutton, with a total output of 930 million jin.

This year Guangxi has comprehensively implemented the production responsibility system, stabilized cultivated land for grain crops, increased cultivable land for industrial crops in a planned way and popularized agrotechnology. Localities in southern Guangxi where agriculture is relatively developed have reaped a bumper harvest as well as mountainous districts in western Guangxi where production levels are relatively low. Grain output in counties in the south including Yulin, Beiliu, Rongxian, Luchuan, Bobai, Pingnan, Qinzhou, Hepu, Pubei, Lingshan, Yongning and Hengxian, have all exceeded 100 million jin. A large number of "outstanding peasant households" each of which has produced 20,000 jin of grain and has an income of over 10,000 yuan have emerged in rural areas in various localities.

CSO: 4007/67

BRIEFS

GRAIN PRODUCTION--The autumn harvest in Guangxi region has basically ended. Total output of grain of the region for the whole year reached some 25 billion jin, an increase of some 2 billion jin over last year. This is a record year since liberation. [Nanning Guangxi Regional Service in Mandarin 1130 GMT 24 Nov 82 HK]

RAMIE PRODUCTION--Ramie production in Guangxi region has increased this year. According to statistics, by the end of October all supply and marketing departments throughout the region had procured some 28,000 dan of ramie, some 9,000 dan more than in the corresponding period last year. [Nanning Guangxi Regional Service in Mandarin 1130 GMT 17 Nov 82 HK]

MID-SEASON RICE--By 21 October, Guangxi region had reaped some 1.42 million mu of mid-season rice, which accounted for 52 percent of the sown area. In this period, the region had reaped 240,000 mu of mid-season rice more than in the corresponding period last year. Hechi Prefecture had reaped 300,000 mu of mid-season rice, with its total output being some 34 million jin more than last year. Wuzhou Prefecture reaped some 47,000 mu of mid-season rice. [Nanning Guangxi Regional Service in Mandarin 1130 GMT 26 Oct 82 HK]

NANNING PREFECTURE WINTER SOWING--By 20 October, Nanning Prefecture in Guangxi region had carried out winter sowing on 928,000 mu, which was 100 percent larger than last year. The prefecture had cultivated green manure, buckwheat, sweet potatoes, vegetables and beans on some 110,300 mu. To strengthen leadership over winter sowing, all counties and communes must each assign a leading member to take charge of this work and send relevant personnel to grassroots units to sum up and popularize typical experiences. All trades and departments must support winter sowing. [Nanning Guangxi Regional Service in Mandarin 1130 GMT 26 Oct 82 HK]

GOOD AUTUMN GRAIN HARVEST REPORTED

OW081209 Beijing XINHUA in English 0804 GMT 8 Dec 82

[Text] Shijiazhuang, 8 Dec (XINHUA)--Hebei Province reaped 12 million tons of autumn grain to raise the annual output to 16.5 million tons, 8.5 percent more than last year, the provincial statistical department said.

One of the nation's major grain and cotton producers, the province also got a record cotton harvest of 325,000 tons, 46.7 percent above last year's and the output of oil-bearing crops was above 50,000 tons, 7.5 percent more than last year, it said.

At the end of November, the north China province had set aside 2.23 million tons of grain and 295,000 tons of cotton for state purchase, surpassing the annual state quotas by 3.3 percent and 18.9 percent, respectively, the department said.

Eight counties reported that they have doubled their 1978 output value. Seven of them are in the disaster-ridden, low-yielding Heilonggang area in the eastern part of the province.

The department attributed the good harvest to an increase in hectarage planted to grain and cotton and scientific farming.

The hectarage planted to cotton increased from last year's 530,000 hectares to 713,000 hectares this year, and the hectarage planted to sorghum, millet and sweet potatoes also increased.

The peasants, the department said, were motivated by the production responsibility system, which has been instituted in more than three-fourths of the total production teams. With greater power of management and increased profits under the system, the peasants planted crops best suited to local conditions and applied the latest agrotechniques. The provincial agrotechnical department organized training classes, signed technical contracts, provided technical information and set up demonstration centers to spread agrotechniques urgently needed by the peasants.

Companies that provide insecticidal services were set up in 383 people's communes and 570 technicians contracted with the peasants to provide plant protection services. The department said most of the peasants in the province have some knowledge of the scientific application of fertilizer, rational close planting, seed selection and systematic management.

CSO: 4007/67

BRIEFS

BUMPER HARVEST--Hebei has reaped a bumper autumn harvest. Grain output is expected to reach 24 billion jin, 1.1 billion more than last year, and cotton production is expected to reach 650 million jin, 200 million more than last year. Oil-bearing crop production is more than 1.1 billion jin, which is higher than last year. The fundamental reason for this success is that the province is practicing responsibility systems. According to statistics, 78.3 percent of production teams have instituted the system of assigning the land to the households in exchange for fixed levies or the system of fixing output quotas for each household, and 73.3 percent of these teams are practicing the system of assigning contracts to each household, compared with 29 percent last autumn. Apart from that, the province readjusted crop areas to suit local conditions. The sown area of cotton was 34 percent greater than last year. Scientific cultivation was further popularized. [HK180735 Shijiazhuang Hebei Provincial Service in Mandarin 0400 GMT 17 Nov 82 HK]

AUTUMN WHEAT SOWING--Shijiazhuang, 1 Nov (XINHUA)--Hebei Province has completed the task of autumn wheat sowing. The total area sown to autumn wheat reached over 35.5 million mu, an increase of 2 million mu over 1981. Prior to starting the wheat sowing task, the province, one of the major wheat-producing areas in China, took various measures to popularize scientific knowledge about wheat sowing among the peasants and conducted training classes for some 1.4 million cadres, peasant technicians and commune members. The total amount of phosphate fertilizer applied in the province this year increased by 100,000 dun over last year, and the amount of cake fertilizer applied increased by 70 million jin over last year. [Beijing XINHUA Domestic Service in Chinese 0025 GMT 1 Nov 82 OW]

RURAL WEEKLY--Shijuazhuang, 13 Nov (XINHUA)--A rural weekly known as NONGJIA LE [PEASANT'S JOY] has been jointly published by HEBEI RIBAO and the Hebei Provincial Supply and Marketing Cooperative. It disseminates agricultural and sideline occupational knowledge as well as market information. Over 90 percent of its subscribers are peasants in the province and more than 170,000 copies were sold in 8 months ending October 1982. It was first published last February. HEILONGJIANG CALLS FOR CORRECTING SOIL EROSION

SK181219 Harbin HEILONGJIANG RIBAO in Chinese 28 Oct 82 p 2

[Article by Liu Jincheng [0491 6930 2052] of the provincial water conservation bureau and Kiu Yunhe [0491 6663 3109] of the provincial water and soil conservation office, entitled: "Some Noteworthy Problems in Current Water and Soil Conservation Work" from the column "Work Study"]

[Excerpts] Comrade Hu Yaobang pointed out in his report to the 12th CPC Congress that from now on, while firmly controlling population growth, protecting all agricultural resources and maintaining the ecological balance, we must do better in agricultural capital construction, improve the conditions for agricultural production and practice scientific farming. Following this guideline, we should do a lot of work to improve the conditions for agricultural production in the future.

In our province soil erosion areas total 75 million mu, of which 60 million mu are arable land, and 30 million mu are seriously eroded. Soil erosion areas include some 58 towns and counties. Serious losses of water, soil and fertility resulting from water and wind erosion in these areas have made the layer of black earth become thinner and thinner, deteriorated soil structure and reduced the water storage capacity of soil, thus worsening the damage caused by drought and waterlogging. Therefore, we must accelerate our efforts to stop soil erosion. At present, we should carry out the following tasks for water and soil conservation:

1. We should enhance our sense of urgency and responsibility in carrying out water and soil conservation work.

2. We should take the rivulet basin as a unit to tackle problems in a comprehensive way. A rivulet basin which is composed of slopes, ditches and streams is a complete natural water assembly area in which the entire course of soil erosion can be witnessed. In order to effectively control soil erosion, we should implement the principle of simultaneously improving slopes and ditches, combine biological with engineering measures, plant trees and grass and close hillsides to facilitate afforestation at the same time, give play to the function of both farmland improvement projects and farming methods and urge the masses to protect land. With this done, we will be able to prevent mud and

sand from being washed away from ditches in a short period of time, utilize water to the utmost and basically control soil erosion. When soil erosion in revulet basins is successfully tackled, soil erosion in larger areas will be alleviated correspondingly.

3. We should closely combine water and soil conservation with the development of diversified production.

4. We should properly handle the relationship between reclamation of wasteland and water and soil conservation. Over the past few years, some localities have reclaimed wastelands to the detriment of trees and grass and have reclaimed sandy areas, steep slopes and areas near farmlands. This has damaged large areas of vegetation and activated soil erosion. In Mudanjiang Prefecture, more than one-third of the natural secondary forests with a slope of 10 to 30 degrees on the outskirts of towns along railways have been damaged. Dense forests have been turned into barren lands covered all over with wounds. In order to prevent such a situation, we should strictly forbid reclamation of land to the detriment of forests. We should turn the farmlands on slopes of more than 15 degrees into forests again. If such farmlands cannot be turned into forests because the population is great and farmlands are limited, we should build water and soil conservation projects to prevent erosion.

5. We should implement economic responsibility systems. In areas where soil erosion is serious, there are comparatively more poor communes and brigades whose economy is rather weak. If we are to tackle erosion more quickly, we should adopt various economic responsibility systems to assign every work group and individual the responsibilities to manage land and keep it in good maintenance and arouse their enthusiasm for protecting water and soil conservation projects.

AGRICULTURAL ECONOMIC STATISTICAL WORK REPORTED

SK250910 Harbin HEILONGJIANG RIBAO in Chinese 1 Nov 82 p 2

[Article by Zhao Zongde [6392 1350 1795] of the provincial agricultural bureau entitled: "We Must Attach Importance to Agricultural Economic Statistics Work" from the column "Work Study"]

[Excerpts] The implementation of all forms of production responsibility systems in the rural communes and brigades has promoted the development of the collective agricultural economy. At the same time, owing to the increase in the forms of contract, reward and punishment systems, some contract households have understated their output and income figures to the production teams, bringing difficulties to the correct compilation of agricultural economic statistical data. Calculated in accordance with investigations into exemplary cases in various localities, in 1981, rural basic accounting units throughout the province failed to report to the production teams an income totalling 12 million yuan, 2.8 percent of the total annual income. Each person failed to report nearly 7 yuan in income on the average.

The creation of the above problems, on the one hand, is because of the short period of time, the lack of experience and our failure to keep pace in time with the changes in the forms of management to formulate a set of accounting and statistical systems that suit the new situation. On the other hand, some comrades lack a sufficient understanding of the importance of the strict statistical work.

Economic statistics are at all times the important links of economic work. Take the statistics of income distribution of rural communes and brigades, for instance. First of all, they are a component of the statistical data of the whole national economy. The accuracy of the statistical data will directly affect the correctness and reliability of the national economic statistical data. Second, only complete income distribution data can correctly reflect the labor achievements of the collectives and the commune members, thus further arousing the production enthusiasm and labor zeal of the cadres and the masses. Third, economic statistical data are a foundation for implementing economic accounting. Only by collecting accurate economic data from all quarters can we analyze and create conditions for correctly carrying out economic activities and can we provide scientific data for selecting the best economic result.

At present, to do a good job in the agricultural economic statistical work, we must grasp several crucial links.

1. Leaders at all levels must not only ideologically attach importance to statistical work, but must also consider it as an important matter in economic work. They must make good arrangements, conduct good surveys and arouse the attention of the low-level organs and pertinent business departments to work in coordination and to realistically grasp the work well.

2. In view of the fact that the crux of the incorrect data lies in the income and expenditures of the contract household portions, which are not in the account and that the reason for the incorrect data is mostly because of the contract workers' insufficient understanding of the party's policies, therefore, we must consider the statistical work of the contract household portions as the main point in solving the problem of failing to report real incomes and expenditures and must do a good job in publicizing policies.

3. We must rely on the pertinent business departments to make necessary supplementary forms for reporting statistics.

4. We must strengthen professional training for accountants and statisticians of communes and brigades so as to raise their professional skills to a new level. In addition, we must institute a personal responsibility system in statistical work, define work tasks and quality requirements so as to enhance the professional workers' dedication and their sense of responsibility in striving to raise the quality of statistical work.

PRESS COMMENTS ON FISH FARMING

SK070409 Harbin HEILONGJIANG RIBAO in Chinese 15 Nov 82 p 1

[Text] Our province is rich in aquatic resources. The water areas suitable for fish farming ranks the province fifth in the country. However, only 40 percent of the total water areas have been exploited and most of them are left unused. It is a pity that such abundant resources lie idle.

There are many reasons for the low utilization rate of water area. One of them is that in the past we paid much attention to unified management to the neglect of individual and decentralized management. To solve this problem, first of all, we must change the guiding ideology of relying solely on centralized management of the state and collective to one that calls for simultaneous participation of the state, collective and individual.

Our province is in the initial stage of developing fish farming by individuals. Therefore, leaders at all levels should emancipate their minds and soften the policy to rationally delimit fishing areas and to adopt diverse forms of management. Special attention should be paid to mobilizing the initiative of tens of thousands of households and to enthusiastically encouraging and supporting them.

We should firmly attend to delimiting the odd pieces of fishing areas or fishing areas not suitable for collective management among commune members. Some localities would rather leave unused small puddles and small low-lying ponds that are not fit for collectives to exploit, than assign them to commune members. However, some localities have assigned fishing areas to commune members, and once those commune members earn a large income from raising fish, the fishing areas assigned to them are taken back. It is wrong to act like that.

The resolution made by the provincial government on the development of fishery clearly defines: state, collective and individual ownership of water areas are protected by law.

Both parties may sign contracts through negotiation with regard to what assistance the collective should render to the individual household engaged in fish farming and what the obligations of the latter are.

In short, efforts should be made to fulfill our goals--fishes are raised wherever there is water, whoever is suitable for fish farming can be engaged in it and the more fishes raised, the better.

BRIEFS

BIN COUNTY VISITED--Prior to the arrival of the severe cold winter, leading comrades of the provincial CPC committees and government visited the mountainous areas. On 8-10 November, Yang Yichen, first secretary of the provincial CPC committee; Chen Junsheng, secretary of the provincial CPC committee; Wei Zhimin, deputy governor, and (Yang Yusheng), Standing Committee member of the provincial CPC committee and chairman of the provincial government agricultural office, visited communes, brigades and commune members in Bin County that had been heavily stricken by natural disasters. The visitors asked about their situations in production, livelihood and reconstruction through self-reliance, listened to their questions and opinions and encouraged them to boost their morale, to rely mainly on the collective and their own efforts and to adopt appropriate and reliable methods to boost the production of collectives and the household sideline occupations of commune members. [Excerpt] [SK120756 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 11 Nov 82]

SAVINGS DEPOSITS--By the end of October, savings deposits of the urban population in Heilongjiang Province totaled 2.19 billion yuan, an increase of 441 million yuan over the end of 1981 and overfulfilling the annual savings deposits plan. [Harbin HEILONGJIANG RIBAO in Chinese 10 Nov 82 p 1 SK]

HEIHE PREFECTURE AGRICULTURE--In Heilongjiang, Heihe Prefecture plans to increase its agricultural output value by 7 percent annually so as to increase its agricultural output value from 380 million yuan in 1980 to 1.56 billion yuan by the end of this century. The prefecture's favorable conditions for the increase are its 6.5 million mu of cultivated land, averaging 9.5 mu per capita; its 1.8 million mu of wasteland suitable for reclamation; its 75 million cubic meters of timber reserves; its 10 million mu of barren hills and land suitable for afforestation; its 9 million mu of good grasslands, of which only 20 percent are utilized; its 1.2 million mu of usable water areas, of which less than 2 percent is used currently; and its 570,000 watts of hydropower potential. In addition, it has 4,975 large and medium-sized tractors, 1,991 combine harvesters and 21,000 motor-driven farm tools. Its farm mechanization rate has increased to 80 percent. The prefecture plans to gradually increase its output value of forestry, animal husbandry, sideline products and fishery from the present 18 percent to 58 percent in the total agricultural output value. It also plans to increase its cash crop areas from 4 percent in the total sowing areas to more than 10 percent. [Harbin HEILONGJIANG RIBAO in Chinese 18 Oct 82 p 2 SK]

CONTRACT SYSTEM--Shuangcheng County Food Company has instituted an economic contract system in dealing with poultry, thus boosting workers' enthusiasm and scoring remarkable achievements. The company has purchased 185,000 chickens, ducks and geese so far and earned a profit of 151,000 yuan, 14 percent more than in the same period last year. This year the company changes the method of eating from the same big pot of rice in carrying out the poultry business and instituted the economic contract system in a comprehensive way. The company assigned fixed profit quotas to its food stations. When the quotas are fulfilled, the stations share 70 percent of their above-quota profits and the company shares the remaining 30 percent. The more they earn, the more they share. When the stations fail to fulfill their quotas, they are subjected to a fine equal to 30 percent (?of their assigned quotas). Such a system has fired the workers with great enthusiasm. [Excerpt] [SK150854 Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 14 Nov 82]

DAIRY PRODUCTION INCREASED--Harbin, 27 Nov (XINHUA)--Heilongjiang Province, one of China's major dairy producers, turned out a record 22,000 tons of dairy products by 15 November, fulfilling its annual quota 1 1/2 months ahead of schedule. Last year the province produced 18,000 tons. The provincial light industry bureau predicted that an additional 3,000 tons of dairy products will be produced before the end of the year. Heilongjiang's 62 dairies, capable of processing 1,000 tons of milk daily, produce one-fourth of the nation's total dairy products including milk powder, condensed milk, cheese and butter. The province has 120,000 head of milch cows, of which 47,000 are kept by peasant households. The bureau said 20 dairies have been expanded this year to process 400 tons more milk daily. The new Anda milk plant, which has complete sets of equipment imported from Denmark, will process 200 tons of milk daily upon completion in 1984. Heilongjiang's dairies now provide a variety of milk powder products, including chocolate milk powder and milk powder specially for infants and pregnant women. This year, they produced 1,000 tons of milk-bean powder, a new mixture of milk and soybean powder and sugar. [Text] [Beijing XINHUA in English 0735 GMT 27 Nov 82 OW]

BEET SUGAR INCREASE--Harbin, 26 Nov (XINHUA)--China's leading beet sugar growing province of Heilongjiang expects to produce 400,000 tons of beet sugar in this refining season, 10 percent above last [year], the provincial light industry bureau announced. Heilongjiang, which accounts for about one-half the country's beet sugar output, purchased more than 1.63 million tons of sugarbeets by 10 November. The province expects to harvest 3.3 million tons of sugarbeets this year despite drought and insect attacks. This year, Heilongjiang planted 10,000 hectares more to sugarbeets than in 1981. The 24 refineries started operation in early October. Statistics from these plants show sugar content is 1.5 percent higher this year than last. The province reaped a record harvest of 3.36 million tons of sugarbeets and produced 365,000 tons of sugar in 1981, the bureau said. [Beijing XINHUA in English 0715 GMT 26 Nov 82 OW]

SUGAR PRODUCTION--By 27 November Heilongjiang Province had produced 100,000 tons of sugar. Since 1 October, 24 sugar refineries in the province have gone into operation to process sugarbeets. As of 27 November the province had processed 800,000 tons of sugarbeets. According to a calculation by the provincial sugar company, the province's output of sugar extracted from sugarbeets will surpass 390,000 tons, topping the previous record. [Harbin Heilongjiang Provincial Service in Mandarin 1100 GMT 2 Dec 82 SK]

GRAIN PROCUREMENT--Nenjiang and Suihua Prefectures, Heilongjiang Province, have overfulfilled the state grain procurement targets. As of 10 November, Nenjiang Prefecture overfulfilled the 620 million jin grain procurement target by 30 million jin. As of 13 November, Shuihua Prefecture procured 370 million jin of grain. MEETING ON INDISCRIMINATE TREE FELLING REPORTED

HK300643 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 28 Nov 82

[Text] The provincial government held a telephone conference last night with the participation of leading cadres of various prefectures, cities and counties, which called for deepening understanding, strengthening leadership and properly implementing the central instructions on curbing indiscriminate tree-felling and strictly hitting at the criminal activities of indiscriminately felling trees.

In his remarks at the conference, provincial CPC committee secretary and governor, Dai Suli pointed out: Having issued the urgent instructions, the CPC Central Committee and State Council immediately assigned a work team led by Yang Jie, member of the central commission for discipline inspection, to help investigate and handle cases of indiscriminate tree felling in the province. Most of the prefectures, cities and counties have attached importance to the implementation of these instructions. Leading cadres are personally in charge of planning and handling forest destruction cases. The provincial commission for discipline inspection, public security organs, procuratorial organs and people's courts at all levels, forestry, industrial and commercial departments have taken quick action and assigned work teams to handle tree felling cases in places seriously affected. Through investigating and finding evidence, Nanyang and Xinyang prefectures have arrested a number of tree felling criminals. The evil trends of indiscriminate tree felling have suffered a heavy blow from the closing down of timber free markets, setting up more timber inspection stations, and strengthening forestry management at various localities. However, party and government leading cadres in some counties have failed to earnestly and effectively implement the instructions of the Central CPC Committee and State Council. As a result, such cases as illegally and indiscriminately felling trees, and plundering forests are still developing.

Dai Suli pointed out: The urgent instructions of the CPC Central Committee and State Council are a matter of great importance closely related to the long-term interests of the state and people; they are not only related to the forestry departments but also are of great importance for the leading cadres of party and government organs as well as to the public security organs, procuratorial organs and people's courts. They must be conscientiously and rapidly implemented; they must be handled with meticulous care; they must not be overtly agreed with but covertly opposed; the law must be observed and the trends of mishandling cases should be resolutely changed. In conclusion, Dai Suli put forward the following four points:

1. The CPC committees at all levels throughout the province should restudy and understand the spirit of the central instructions, and take it as an important task governing rural work for this winter and next spring and grasp it firmly; the erroneous view of regarding indiscriminate tree felling as justified must be criticized; all localities should make use of various publicity media to constantly spread propaganda on the central instructions among cadres and masses and make them known to every household. Provincial, prefectural and county leading cadres should be in charge and assign groups formed by commissions for discipline inspection, public security organs, procuratorial organs, people's courts, forestry, industrial and commercial departments to the spots where forests have been seriously damaged, to grasp a number of model cases and handle them seriously, rapidly, vigorously and publicly. Party members who have taken the lead in such activities should be expelled from the party; cadres who have taken the lead should be dismissed and then arrested in order to give warning to the criminals and educate the cadres and masses. In future, the evil trend of indiscriminately felling trees must be curbed rapidly and resolutely.

2. Indiscriminate tree felling cases should be thoroughly investigated, taking counties and municipalities as the unit. A unit or individual who has damaged trees in the past 1 or 2 years should be individually handled in accordance with the specific instance. All compensation must be repaid; all who deserve it must be fined and all who should be convicted must be convicted in accordance with the laws. Tree-felling criminal cases occurring after the issuance of the central instructions should be seriously handled. In cases where people refuse to act on orders or fail to properly handle the cases, the responsibility of the county CPC committee secretary or county magistrate must be investigated; and I think, the prefectural CPC committee secretary and special commissioner should also be investigated, and that the provincial authorities should also be held responsible.

3. Strictly implement the system of tree felling authoritization, transport and management. Tree felling, timber transport and marketing are not allowed without the written authorization of the forestry departments. Timber free markets in forest areas or near forest areas must be resolutely closed. Timber processing factories should be straightened out. Government in all localities should assist timber inspection and management departments in their work.

4. Do a good job in the three fixes in forestry and in winter-spring tree planting. All localities should proceed with their work in a planned way in the light of curbing damage to trees, the three fixes in forestry and winter-spring tree planting. Tree felling in forest lands where the three fixes have not been completed should be temporarily suspended. Hills that are to be assigned to commune members should be barren hills, and forest tracts should not be distributed to individuals. Tree belts on farmland and the interplanted trees on farmland should be managed in a unified way if that can be done, and the trees that have been assigned with the land should be strictly managed and the unauthorized tree felling should be banned. In future, the building of tree belts on farmland should be completed under unified plans.

LIU JIE ADDRESSES MEETING ON FORESTRY

HK030905 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 1 Nov 82

[Summary] Recently the Henan Government held a provincial meeting on forestry. Liu Jie, first secretary of the provincial CPC committee, attended the meeting and delivered a speech.

"Developing forestry is a great strategic measure that is of vital and lasting importance. It is imperative to grasp this work well. Henan is rich in the resources of tree varieties and has good natural conditions. There are 55 million mu of land suitable for planting trees and 16 million mu of waste land that need to be forested. Henan has great potential for developing forestry. We have 30 years' positive and negative experiences, a backbone rank in forestry and a number of advanced models. Provided that we work hard, it is entirely possible to cover up 30 percent of the land with trees, quadruple the storage of timber and increase to a large extent the total output value of forestry by the end of this century."

In the past, forestry was influenced by the erroneous ideas of the "leftist" deviation. Implementing the three-fixes system, that is fixing the leadership, personnel and task has great significance in promoting unity and stability, protecting the forests and eliminating the erroneous influence of the "leftist" deviation.

"The meeting stressed that while implementing the three-fixes system, it is necessary to organize the forestation of this winter and next spring, draw plans for the forestry areas, make preparation for saplings and rationally arrange the variety of trees. The forestation tasks should be gradually fulfilled down to every unit and peasant family. After the wheat planting and before early January 1983, we must organize three upsurges in planting trees. It is necessary to accomplish the task and guarantee both quality and quantity. We must also grasp the collection and storage of seeds and the transplanting of saplings during winter to solve the problem of shortage of saplings in afforestation."

"The meeting demanded that various localities firmly carry out the emergency instruction of the party Central Committee and the State Council on checking the indiscriminate lumbering and cutting of forest trees and regard this as an important task. Special forces must be organized to conduct an overall examination of the work of protecting forests. Those who seize state or collective property must be thoroughly investigated and punished according to law. Those units and individuals who damage forests must be seriously handled according to the gravity of the case. The unhealthy tendency of indiscriminate cutting and lumbering should be seriously handled and resolutely checked."

Directors and responsible comrades of forestry departments of the prefecture levels and representatives of the concerned units of the provincial level totalling 350 people attended the meeting. At the end of the meeting, Vice Governor Yan Jining made a summary to the meeting.

CSO: 4007/67

COMMENTARY ON RATIONAL USE OF LAND

HK010723 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 30 Nov 82

[Station commentary: "We Must Make Rational Use of Land"]

[Excerpts] In the past few years, given the development of the socialist construction cause, an increase in population and a reduction in the land available, there have appeared many contradictions with regard to the use of land for construction interfering with national economic construction. This problem should arouse the close attention of the leadership at various levels and must be seriously solved. Ours is a socialist country. Its land belongs to the state and the collective. No unit or individual has the right to occupy, or buy and sell the land.

To meet the needs of socialist construction, the state can requisition land in accordance with legal provisions. Therefore, the departments requiring land for construction and the cadres and masses of communes and brigades affected in the requisition of land must correctly handle the relationship between the state, the collective and the individual and make rational use of land in line with the needs of national construction. Our country has a large populating but little land. The average cultivable area per capita is lower than the world level. That in our province is also lower than the national level.

All construction units that occupy cultivable land must resolutely carry out the state regulations governing the requisition of land. In line with the principle calling for economic and rational use of land, they must make rational use of land and raise its utilization rate. We must resolutely overcome the chaotic situation in which units defying state policies and degrees freely occupy land without authorization, occupy more land than is authorized, requisition more land than is required, requisition land not for use, or precede with the occupation of land together with the act of making a requisition. Making proper arrangements for the peasants of communes and brigades affected by the requisition of land with regard to their lives and production, is also a problem that must be properly solved. After requisitioning a piece of land, we must provide rational economic compensation in line with the specified regulations and properly settle the displaced persons concerned. It must be pointed out that in the past few years, some communes and brigades have extorted irrational compensation for land to be requisitioned for national construction, freely making extra demands. Where their demands have not been satisfied, they have refused to hand over the piece of land to be requisitioned. In defiance of law and discipline, some have purposely dug ditches and destroyed roads interfering with the normal progress of national construction. This can never be allowed. Governments and land control departments at all levels must strengthen leadership and resolutely uphold the regulations governing the requisition of land for national construction. We must conduct education among the units requisitioning land. Thus, they know that they must pay attention to conserving every inch of land and raising its utility rate. We must also pay attention to the idea of jointly contributing to the construction effort, respond to the state's needs and actively support the state in requisitioning land. In a word, everyone must pay attention to the concept of the whole situation, in order to insure the smooth progress of modernization.

HENAN

DISCUSSION ON PROPER USE OF LAND

HK010733 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 30 Nov 82

[Text] From 18 to 25 November in Zhengzhou, the provincial construction committee held a forum on Henan Province's regulations governing the requisition of land for national construction. Participating at the meeting were directors of the construction committees of various prefectures and municipalities and some counties, and responsible comrades of the relevant departments and bureau directly under the province. The Standing Committee of the provincial people's congress and the provincial government also sent people to attend the meeting. Yue Xiaoxia, vice governor or Henan, attended and addressed the meeting.

The comrades attending the meeting seriously studied the regulations governing the requisition of land for national construction promulgated by the State Council, and examined and analyzed the following problems existing in our province's use of land for construction in the past few years:

1. Some leading comrades do not have an adequate understanding of the national policy on the protection of farmland and take no notice of state policies and decrees, freely encroaching upon and occupying land.

2. No satisfactory arrangements are made for the masses of communes and brigades affected by the requisition of land in regard to their lives and production, causing bad blood between the units requisitioning land and the local people affected.

3. Prompted by partial and individual interests, the cadres and peasants of some areas bargain hard with the units requisitioning land, wasting time and hampering the normal progress of necessary construction projects.

4. Organs in charge of land leave something to be desired. There are not enough personnel specialized in management. Relevant work fails to catch up, so that many problems are not promptly taken care of.

On the basis of studying the regulations governing the requisition of land for national construction promulgated by the State Council and analyzing the actual conditions of our province, the meeting discussed a draft concerning Henan Province's regulations governing the requisition of land for national construction.

Guided by the principle of treasuring every inch of land and guaranteeing national construction projects, the draft put forth a series of rules and regulations to be followed in implementing the State Council's regulations. From the legal point of view, effective measures were formulated concerning the chaotic state witnessed in the use of land for construction. The draft will be submitted at the Standing Committee of the provincial people's congress. After being examined, it will be promulgated by the provincial people's government for implementation.

The meeting called on land control departments at all levels, various units requisitioning land for construction and the masses of communes and brigades throughout the province to take the whole situation and all interests into consideration, foster the spirit of making a joint contribution toward construction, and fight for the realization of the four objectives of struggle put forth at the 12th CPC National Congress.

URBAN RESIDENTS RETURN TO RURAL AREA

HK021100 Beijing RENMIN RIBAO in Chinese 30 Nov 82 p 1

[Report by reporter Xin Qing [1800 1730] and correspondents Ying Jun [5391 0193] and Tong Liang [0681 5328]: "Great Changes in the Rural Areas Since the Implementation of the System of Assigning Land to Each Household in Exchange for Fixed Levies--Townspeople of 170 Households in Shenqiu County Ask To Return to Rural Areas"]

[Text] Exciting news comes from Shenqiu County in eastern Henan, which has experienced a drastic change in the last 3 years: townspeople of 170 households which were transferred to rural areas and which had tried every means to petition to return to the urban area, are now vying with one another to return to the rural areas.

In the past, since there was a tremendous gap between the urban and the rural areas in Shenqiu County, which used to suffer from natural disasters, urban residents always refused to move to rural areas. Three hundred and five urban households which were transferred to the countryside during the 10 years of turmoil, saved their money to organize petitions, strongly demanding to return to urban areas. Since the system of assigning land to each household in exchange for fixed levies was implemented, the grain output per unit area of the production brigades to which they belong has increased from more than [figure indistinct] jin per mu to more than 800 jin per mu, while the income per capita has increased to 185 yuan and the grain distribution per capita to more than 500 jin. In addition, rural households can enjoy large houses. Therefore, 170 households which have already completed application for returning to urban areas are now asking to return to rural areas.

CPC REPORT ON COUNTY PEASANTS' JOYS, WORRIES

HK121516 Zhengzhou Henan Provinoial Service in Mandarin 1100 GMT 10 Nov 82

[Excerpts of report, "The Joys and Worries of Peasants," by (Du Guanzhang), member of the policy study office of the Henan Provincial CPC Committee, on rural areas in Hua County]

[Excerpts] The report says: In September and October, I returned to my hometown, rural Hua County, and stayed there for some time. I was deeply impressed by some circumstances. Now peasants' enthusiasm for production has been really aroused. I have never before seen the peasants in my home town so happy as they are now. I have also never before seen their enthusiasm for farming so great as it is now. In the past, Hua County was a poor place. During the 10 years of internal disorder, it was exceptionally seriously sabotaged by the left. In the production team where my home is situated, the annual per capita wheat ration had seldom reached 100 jin for many years in the past. In 1981 when the system of assuming full responsibility for fixed output quotas was implemented, the per capita wheat ration in that year as some 400 jin. The per capita wheat ration this year has increased to some 500 jin. Due to the autumn hailstones disaster this year, we basically had a bad harvest of cotton and sesame and could only reap 40-50 percent of such crops as corn and beans. Even so, grain output was more than in previous years. I went to visit my neighbors door-by-door and all of them, male and female, old and young, greeted me with a smiling face.

However, peasants also have their worries. The main worry is that they cannot sell the agricultural products which they want to sell and they cannot buy the industrial products which they want to buy. Peasants have a lot of complaints about the fact that the supply of the means of production and the means for their livelihood cannot be guaranteed. They have to pay high prices for many things. The masses of commune members have also disclosed that paying high prices for things is a minor matter and what worries people most is that they are fooled and deceived and that they cannot rest assumed when they buy things. Diesel oil, seeds and fertilizers are sometimes not genuine ones. Peasants say that they do not mind spending more money and that when they buy spurious diesel oil, which will damage machines, and when they buy false seeds and chemical fertilizers, which will affect a season's production, they cannot afford these losses. There are many loopholes in the service for peasants' livelihood. For example, places where peasants have noodles are a big problem. Now peasants have put forward many views on the management of the market and commodity prices. They urgently hope to have a rural purchase and sales system which can uphold peasants' proper interests, provide good service and do business justly and are trusted by the masses. It is necessary to do well in the service work for agricultural production and peasants' livelihood and to prohibit improper businesses so as to rid peasants of their worries and make them engage wholeheartedly in production.

BRIEFS

GRAIN PROCUREMENT--Henan had overfulfilled its autumn grain procurement quota by 24.73 million jin by 25 November, despite the fact that the harvest was affected by natural disasters. The crops procured include 195.31 million jin of soybeans and 14.35 million of sorghum. [HK060759 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 4 Dec 82 HK]

COMMUNE MEMBERS' SAVINGS--Since the 3d Plenary Session of the 11th CPC Central Committee, the amount of savings of rural commune members in Henan Province has greatly increased. By the end of October, the amount of savings of commune members throughout the province which were deposited with credit cooperatives had amounted to 1.274 billion yuan, which was 310 percent more than in the corresponding period in 1977 when the amount of savings was only 310 million yuan. The average per-capita savings of commune members in Lin and Meng counties were 97 yuan and the average savings of each household were 466 yuan, the highest of all counties and municipalities throughout the province. [Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 13 Nov 82 HK]

AGRICULTURAL SITUATION--Zhengzhou, 28 Oct (XINHUA)--In 1981, Henan Province's total agricultural output value (based on 1970 prices) reached 12.13 billion yuan, topping 1978 by 22.8 percent. The 1981 per capita net income of the province's rural peasants was 115.6 yuan, more than double the 1978 figure; the figure for the first half of this year was 105.5 yuan, 40.7 percent more than the same period last year. In 1981, the province's total grain output reached 43.6 billion jin, 10.4 percent more than 1978. This year's total production of summer grain and rapeseed reached 22.7 billion jin and 5.22 million dan respectively. Compared with 1978, the province's 1981 output of cotton, tobacco and rapeseed rose by 58.4, 29.8 and 130 percent respectively. By the end of 1981 the province had a record high of 6.071 million draught animals in stock, 17.9 percent more than 1978. In 1981, the province procured 6.34 billion jin of grain, 32 percent more than 1978. This year it procured 4.26 million jin of summer grain. [OW100259 Beijing XINHUA Domestic Service in Chinese 1239 GMT 28 Oct 82 OW]

AUTUMN GRAIN PROCUREMENT--By 15 November, Henan Province had procured and stored in granaries 1.20736 billion jin of autumn grain, which is 83.7 percent of the province's quota for autumn grain procurement and storage. Nanyang and Xinyang Prefectures have stored 359.69 million jin of autumn grain. [HK221316 Zhengzhou Henan Provincial Service in Mandarin 1100 GMT 21 Nov 82 HK]

STOPPING EXTORTION AGAINST SPECIALIZED HOUSEHOLDS URGED

HK290734 Wuhan Hubei Provincial Service in Mandarin 1100 GMT 28 Nov 82

["Broadcast Talk" by Hubei Radio editor: "Stop Extortion Against Specialized Households"]

[Text] Recently a series of cases in which specialized peasant households were extorted occurred in a few places of our province. For example, there is a peasant called (Li Lincheng) in Zaolin County who engages in some specialized undertakings and has gained comparatively high income. Some cadres there concocted various pretexts and took various opportunities to force him to contribute money. They said to him: The 12th Party Congress is to be held, what are you ready to do to show your feelings? The national day will come, how will you celebrate it? In this way, they openly extorted money from him. In some other places, specialized peasant households were required to give generous and selfless assistance to other peasants who wanted to buy bicycles and sewing machines. These events embarrassed and vexed specialized peasants.

Specialized and key peasant households represent a new situation emerging after the implementation of the agricultural production responsibility system in the rural areas. They have changed the previous semi-[word indistinct] production into the present commodity production and changed the previous extensive cultivation into the present intensive and meticulous farming. They are also keen on adopting advanced technology in their agricultural production and developing diversification. As a result, their productivity has greatly improved and their incomes have increased and are higher than the average as compared with other ordinary peasants. They have become rich sooner than others. Their incomes, which are gained through hard work, should be protected by society. If anyone randomly apportions levies or duties on them, he is violating their lawful interests and the socialist principle of distribution according to work.

Why did the cases of extorting specialized households occur in some places? The radical reason is that the influence of leftist ideology is still making trouble. Some people who have been seriously influenced by the leftist ideology are accustomed to eating from the same big pot and practicing egalitarianism. When seeing that specialized households have become rich through labor, they cannot help but rack their brains trying to receive some privileges from the specialized households. Therefore, the fundamental way to overcome these evil things is to further eliminate the influence of leftist ideology. We should cast aside the notion of "poverty leading to revolution and wealth leading to revisionism"; rather, we should take the view that becoming rich through labor is glorious. We should sincerely support specialized households to become rich through labor. At the same time, it is necessary to educate commune members to learn from specialized members and their advanced experienced in developing production and to take the road of becoming rich in a health way. Only in this way can the rural areas as a whole gradually become prosperous under the guidance of the party's correct policies.

BRIEFS

PEASANTS' INCOME INCREASES--The Hubei Provincial Statistical Bureau has conducted investigation of the economy of 948 peasant households in 30 counties. The investigation reveals that the average per capita net income of peasants in the province this year amounts to 260.2 yuan, 42.7 yuan more than last year. This is the highest record since the founding of the country. The increase in peasants' income is the result of the stability and constant perfection of the agricultural production responsibility system and the vigorous development of household sideline production. It is estimated that the average per capita income from household sideline production in the rural areas in the province this year may amount to 113.6 yuan. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 7 Nov 82 HK]

GRAIN STORAGE--Hubei reaped a bumper grain harvest this year, and the progress of grain storage is unprecedented. By 20 November, more than 6 billion jin had been stored, a record to date. By now 3.2 billion more jin of grain have been procured than at the same time last year. Departments concerned expect the province's grain output this year to increase by 3.8 billion jin--11.3 percent--over last year and to show an increase of 1 billion jin over the previous record year. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 26 Nov 82 HK]

YEAR-END DISTRIBUTION--After conducting experiments at selected units, Hubei Province has started year-end distribution in rural areas. Since October, the province has sent some 15,000 cadres, 242 of whom are principal prefectural and county responsible comrades, to rural areas to set up some 3,000 experimental units in distribution. The experiences of these experimental units have shown that resolutely fulfilling contracts is the central work of doing well in year-end distribution this year. [HK071326 Wuhan Hebei Provincial Service in Mandarin 1100 GMT 1 Dec 82 HK]

LATE RICE--Hubei has reaped a bumper harvest of double-crop late rice. The 12 million mu of the crop have yielded over 5.7 billion jin, an increase of 900 million jin over last year. Average yield was 470 jin per mu, 32 jin higher than the previous high in 1979 and 66 jin higher than last year. The yield exceeded 500 jin in Hanyang, Honghu, Mianyang, Xishui, Huanggang, Huangmei, Xiaogan, Huangji, Yunmeng and Hanchuan counties. [Wuhan Hubei Provincial Service in Mandarin 1100 GMT 19 Nov 82 HK]

ANIMAL HUSBANDRY--The 6-day-long provincial animal husbandry work conference concluded yesterday in Wuchang. The conference reviewed the experiences of animal husbandry production in recent years and commended a group of progressive collectives and individuals on this front. The conference decided on the following main tasks in animal husbandry for our province next year: taking the improvement of economic results as the focus, while continuing to speedily develop the pig-raising industry and striving for an all-round increase in all kinds of domestic animals and fowl; making efforts to fulfill or overfulfill the state plans of purchasing animal products; further improving the supply of meat, milk and eggs to large and medium-sized cities. Meeting participants felt that to achieve the above objectives, it is necessary to implement all relevant policies, energetically encourage peasants to raise domestic animals and poultry on an individual base and energetically develop more specialized households engaged in this trade, with a projected number of households reaching 200,000 in 1983. The conference also studied plans, measures and policies for achieving the goal of quadrupling animal husbandry production in our province by the end of this century. COMMUNES, BRIGADES CORRECT FINANCES

HK021052 Changsha Hunan Provincial Service in Mandarin 1100 GMT 1 Dec 82

[Text] In the course of perfecting the agricultural production responsibility system, communes and brigades in rural areas of Hunan Province have been universally straightening out their finances. According to the statistics compiled by relevant departments, by the end of October 27 percent of the production teams throughout the province had completed straightening out their finances, 18 percent of the production teams were in the process of straightening out their finances and a large number of production teams had planned to unfold this work in the coming winter and spring.

For many years in the past, communes and brigades in our province had not straightened out their finances in a true and systematic manner. Some communes and brigades had more problems. While straightening out finances and in the light of the new situation following the implementation of the system of peasant households assuming full responsibility for task completion, many communes and brigades concentrated their forces and seized on the key point in order to lay stress on the solution of three problems:

1. They did well in checking on, managing and using collective property and gave full play to the role of collective property. What collectives need, such as large machinery, water conservation facilities and antidrought machinery and tools, must be owned by collectives and managed by special persons. They established the system for management, repairs and use. Properties which collectives did not need at the moment, were generally sold to households at the market price. The money from sales was regarded as accumulation funds.

2. They cleared up creditors' rights and debts. They settled all accounts before implementing the system of peasant households assuming full responsibility for task completion and established new economic relations after implementing the system. They laid stress on settling all accounts between commune members, recovering money which cadres had misappropriated or overdrawn and returning to collectives property which had been seized. Items were settled one by one and made public by each household. On the basis of settlement, the method of handling these cases was formulated and the time of repayment was specified.

3. On the basis of settlement, the new accounts and the new management system were established to suit the needs of the system of peasant households assuming full responsibility for task completion. Some communes and brigades implemented the professional accounting system on a trial basis.

BRIEFS

GRAIN PRODUCTION--Hunan has reaped an all-round bumper harvest this year. Changde, Taoyuan, Ningxiang, Changsha, Wangcheng, Liuyang, Liling, Xiangxiang, Xiangtan, Hengnan and Qidong counties and Yueyang Municipality have each increased output by over 100 million jin compared with last year. [Changsha Hunan Provincial Service in Mandarin 1100 GMT 27 Nov 82 HK]

TEA, RAMIE HARVESTS--Hunan has once again reaped a rich harvest of tea leaves. Figures show that by the end of October the province had purchased 1,130,000 dan, an increase of more than 260,000 dan over the same period last year. This year in the 26 major tea producing counties of the province, improvement has been made in procurement quantity, varieties and quality. Meanwhile, the province has also reaped a good harvest of one of its traditional industrial crops--ramie, with a total output of 380,000 dan, an increase of 19 percent over last year. China is the number one producer of ramie in the world and Hunan Province ranks first in the country, accounting for 38 percent of the total output. [Changsha Hunan Provincial Service in Mandarin 1400 GMT 23 Nov 82 HK]

VEGETABLE SUPPLY--A forum held by the Hunan People's Government on the work concerning vegetable supply in the five municipalities under the jurisdiction of the province concluded on 19 November. The meeting discussed some major problems such as insufficient varieties and seasonable greenstuffs and too many rotten vegetables and losses and called for working solutions. In order to improve such a situation, the meeting called on the leaders at various levels to further emancipate their minds and have more courage to carry out different forms of the production responsibility system. Meanwhile, efforts should be made to improve the income of vegetable growers. Attending and speaking at the meeting were the province's Governor Sun Guozhi and Vice Governor Cao Wenju. PRC'S JIANGSU REPORTS RECORD GRAIN HARVEST

OW070449 Beijing XINHUA in English 0248 GMT 7 Dec 82

[Text] Nanjing, 6 Dec (XINHUA)--Jiangsu Province reaped a record 26.25 million tons of grain this year, three million or 12.1 percent more than last year, according to the provincial government.

Ginned cotton output was 550,000 tons, slightly higher than the record year of 1981. Oil-bearing crops, silkworm cocoons and tea all hit historic highs while aquatic products, pigs and poultry showed varying increases.

All seven prefectures in the province, one of China's main grain producers, reported increased grain output.

Xuzhou and Huaiyin Prefectures in the northern part of Jiangsu used to get lower grain output than Suzhou Prefecture in the fertile Yangtze River Delta. But now they have caught up. Huaiyin Prefecture reaped 4.5 million tons of grain, 700,000 tons more than last year, to become the no 1 grain producer in the province, while Xuzhou Prefecture reaped 3.8 million tons, 200,000 tons more than last year, both exceeding Suzhou's 3.65 million tons.

Apart from cotton growing Nantong and Yancheng Prefectures, the other five prefectures have become market grain suppliers. The provincial government described the feat as "the most encouraging change seen in recent years in the province's grain production pattern."

The provincial government attributed the success to efforts to restructure the farm economy and introduction of the production responsibility system. Beginning last autumn, most production teams contracted their land to peasant households. This spurred production enthusiasm, grain was grown on all idle land and sowing, field management and harvesting were done carefully using scientific methods. While continuing to maintain the original grain growing hectarage, the province took steps to promote the development of forestry, fishery, animal husbandry, and sideline production.

CSO: 4020/31

BRIEFS

AGRICULTURAL PRODUCTION--The total grain output in Xuzhou Prefecture, Jiangsu Province, reached more than 7.66 billion jin, an increase of 500 million jin over 1981 and by 3.2 billion jin over 1977. The annual rate of increase is 11.4 percent. The total output of cotton may reach 1.05 million dan, an increase of 200,000 dan over 1981. The total output of edible oil may [phrase indistinct] 300 million jin, an increase of more than 90 million jin over 1981. It is estimated that the state may procure a total of 1.66 billion jin of grain from the peasants in the prefecture this year, with each peasant contributing more than 230 jin. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 18 Nov 82 OW]

RICE PRODUCTION--The masses in Jiangsu Province have reaped another bumper harvest of rice this year. The average per-mu yield of the 10 million mu of hybrid rice is estimated at 870 jin, increasing by 20 to 30 jin compared with 1981. The total output of hybrid rice in Wujin County reached 190 million jin. [Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 11 Nov 82 OW]

FLOODING REPORTED--Most of the last 10 days of November were rainy in Jiangsu. The whole province generally experienced either moderate or heavy rains, causing waterlogging and "four troubles" to some farmland. According to reports from various localities, about 5 million mu of land in the province were waterlogged. All localities have taken emergency measures to cope with the rains. Personnel have been organized and rushed to the countryside to help dig ditches. During the raining period, Nantong Prefecture repaired and cut drainage ditches in more than 2.5 million mu of land. At present, the prefecture is continuing to cut drainage ditches and tend crops on wet land at the same time. The administrative commissioner's office of Zhenjiang Prefecture has issued an urgent circular calling on all counties to dispatch cadres to production brigades and teams to help the latter dig drainage ditches and lower the water level in inland rivers and ponds. The circular also calls on the counties to organize a full-time work force to dig drainage ditches outside the farmland. By 1 December, the waterlogged land had been drained. [Text] [OW090201 Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 4 Dec 82]

WATER CONSERVANCY--The Ministry of Water Conservancy and Power called a national meeting of water conservancy departments at the Jiangdu pumping station to select outstanding units and good-quality projects. Vice Minister Li Boning this morning presented citations to 32 outstanding units and 42 good-quality projects and designs. Of the 14 national good-quality projects selected, only the Jiangdu pumping station won the national gold medal prize. [Excerpt] [OW230143 Nanjing Jiangsu Provincial Service in Mandarin 1100 GMT 20 Nov 82]

AGRICULTURAL OUTPUT VALUE--According to the provincial statistics bureau, Jiangsu's total agricultural output value in 1981 reached 16.05 billion yuan, an increase of 29 percent over 1978. Jiangsu's total grain output in 1981 reached 50.23 billion jin, an increase of 4.6 percent over 1978. Its total cotton output in 1981 reached 11.27 million dan, while its total oil-bearing crop output was 12.83 million dan, an increase by 18.7 percent and 71.4 percent over 1978 respectively. [Nanjing XINHUA RIBAO in Chinese 20 Nov 82 p 1 OW]

YANGZHOU PREFECTURE AGRICULTURE--Yangzhou Prefecture, Jiangsu, reaped a bumper harvest this year. Its total grain output reached 8.44 billion jin, an all-time high. [Nanjing Jiangsu Provincial Service in Mandarin 2300 GMT 20 Nov 82 OW]

CSO: 4007/67

AGRICULTURAL DEVELOPMENT MEASURES STUDIED

OW290044 Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 23 Nov 82

[Excerpts] Recently the provincial agricultural commission held a forum of experts and professors to discuss and study strategic measures for developing agriculture in light of the specific situation in the province.

At the forum the experts and professors decided on three key things to be grasped in developing agricultural production in the province:

1. Ideologically, we should have a broadened view with regard to agricultural production, land and water conservancy. In agricultural production, we should not just develop rice, wheat and soybean production and forget other things such as milk, eggs and meat. We should guard against acting blindly in destroying forests to make more farmland or in reclaiming land from lakes. Speaking of land, we should not just mean paddy fields and dry fields. We should guard against such practice as using grain fields for other purposes in an effort to diversify production and forget that there is plenty of unexploited land on mountains. With regard to water conservancy, we should not limit our work to building reservoirs, digging canals and erecting dikes but ignore control of water loss and soil erosion and forget the need to protect forests and vegetation.

2. As a strategic measure, we should pay attention to the technical transformation of our agriculture. In this connection, it is imperative to change the present state of our low scientific and technological level in agricultural production. An impending task at this time is to seriously implement the party's policy with regard to intellectuals. Secondly, we should conscientiously help scientific research organizations and agrotechnicians establish and perfect the system of individual responsibility and do a good job in agrotechnical consultation service and in the application of successful research results. Efforts should be made to run training classes for agrotechnicians and to select those households which have successfully applied agricultural science and technology as examples for others to follow. The method of signing technical assistance contracts should be put into practice on a trial basis in an effort to raise the level of scientific farming. At the same time, attention should be given to investment in training

intellectuals for rural work. A number of secondary agricultural schools should be established in rural areas so as to train new-type peasants who have a general educational background with special knowledge in the field of agricultural science and technology.

3. Departments concerned should support agriculture and make arrangements for the masses convenience from the viewpoint of developing and promoting production. Cotton is an item in very short supply in our province. Last June, however, Pengze and Duchang counties had an overstock of 100,000 dan of cotton. The commercial department did not want to purchase more cotton for fear of stockpiling this item. Last year Xiushui County had 5,000 dan of Wulong tea in stock, and no one wanted to purchase it. The county tried to sell the tea to other provinces, but the department concerned refused to give it permission to do so. Experts attending the forum expressed the hope that all departments would have a desire to serve agriculture, uphold the concept to overall interests and pay attention to making arrangements for the peasants' convenience and for promoting production.

HOUSING CONSTRUCTION ON FARMLAND BANNED

OW141554 Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 13 Nov 82

[Excerpts] The Jiangxi Provincial People's Government on 9 November issued a circular on firmly solving the problem concerning unauthorized use of farmland for housing construction. The circular calls on all localities to adhere strictly to the guidelines of the report on firmly solving the problem concerning unauthorized use of farmland for housing construction made by the rural policy research office of the secretariat of the CPC Central Committee and the Ministry of Urban and Rural Construction and Environmental Protection of the State Council. It urges all localities to quickly take resolute measures to stop the unauthorized use of farmland for housing construction.

Concerning Jiangxi's actual situation, the circular sets seven rules:

1. It is necessary to strictly control the use of farmland for housing construction. If farmland must be used for housing construction due to restrictions imposed by natural conditions, the request for the land must be carefully examined before it is approved.

2. In view of Jiangxi's land situation, the existing rule to limit the area of land for commune members' housing construction to 100-165 square meters per family, set by the provincial people's government, remains good.

3. All county and municipal people's governments should rapidly adopt concrete measures to manage the land for rural housing construction in accordance with "regulations governing the management of land for village and township housing construction" promulgated by the State Council and also this circular and in consideration of local conditions.

4. All county and municipal people's governments should set the scope of land plans for peasants' housing construction in accordance with the principles for village and township planning laid down by the former state capital construction commission and the former state agricultural commission.

5. In order to encourage the use of smaller land for housing construction, agricultural tax may henceforth be exempted for 5 to 10 years on the yields from the land which is restored to farmland from residential land in the course of building new housing or renovating old housing.

6. All county and municipal people's government should conduct a large-scale inspection on the unauthorized use of farmland for housing construction this winter or next spring. It is first necessary to resolutely stop the cadres from taking the lead in using farmland for housing construction without authorization.

7. The governments at all levels must strengthen specific leadership and release a number of cadres from various county departments concerned with work among the people and help villages and townships work out overall construction plans. The plans should be formulated as soon as possible on the basis of investigation and study. They should be submitted to county or municipal people's governments for approval prior to implementation.

CSO: 4007/67

BRIEFS

SHANGRAO PREFECTURE ACRICULTURE--Despite this year's flood, which damaged 1.23 million mu of farmland for early rice, Shangrao Prefecture, Jiangxi, still increased its total grain output this year by 400 million jin, or 11 percent over last year. Currently, the prefecture has delivered 745 million jin of grain to the state. The prefecture has also procured 12,400 dan of cotton and 17.21 million jin of fat. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 20 Nov 82 OW]

FUZHOU PREFECTURE AGRICULTURE--Despite this year's flood disaster, Fuzhou Prefecture, Jiangxi Province, has still achieved a good harvest. Total grain output tops last year by some 300 million jin and surpasses the highest previous record by 260 million jin. Production of cash crops, such as rapeseed, soybean, peanut and sesame seed is also high. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 21 Nov 82 OW]

PINGXIANG MUNICIPALITY AGRICULTURE--Pingxiang Municipality, Jiangxi, has increased its grain output this year to more than 730 million jin, a 110 million jin increase over last year. [Nanchang Jiangxi Provincial Service in Mandarin 1100 GMT 20 Nov 82 OW]

QIANG XIAOCHU INSPECTS CHANGCHUN AND JILIN

SK171022 Changchun Jilin Provincial Service in Mandarin 1100 GMT 16 Nov 82

[Text] From 3 to 10 November, Comrade Qiang Xiaochu went to Changchun and Jilin municipalities to investigate and sum up their experiences in wresting a bumper harvest despite the serious drought and to give opinions on the work ahead. While summarizing the practical experiences of various localities, he pointed out: When policies are correct, it is possible to reap a bumper harvest despite serious drought. Fundamentally, it is the party's policies that give tremendous power and arouse the potentially immeasurable wisdom and creativity of the masses.

Comrade Qiang Xiaochu went to Lishu County and Jilin Municipality to hold discussions with 10 secretaries of county CPC committees and two secretaries of suburban area CPC committees. He also went to Yushu, Shulan, Yongji and Jiutai counties to conduct on-the-spot investigations in some communes, and brigades and at the threshing grounds and homes of commune members and to hold talks with cadres in communes and brigades and with commune members. Everywhere, he saw and heard the people acclaim with certainty that the implementation of responsibility systems this year has contributed to the bumper harvest in a year of drought. They expressed satisfaction and ease of mind with the party committee's timely promulgation on not changing the contract procurement tasks, the policy on retaining and purchasing farm crops and the policy on production contracts. They said: It was unexpected that correct policies would bring about a bumper harvest in year of drought. It is the party's policies that brought about a year of good harvest in agriculture and animal husbandry. According to reports from various localities, this year our province had another good harvest, following last year's.

Comrade Qiang Xiaochu called on cadres and the masses to take the guidelines of the 12th National CPC Congress as a weapon to realistically sum up this year's rich experiences in combatting drought to reap a bumper harvest and to make good preparations ideologically and materially for production in the future. Comrade Qiang Xiaochu said: This is an unusual year--a year of excitement, twists and turns and good harvest. We can say that the people of our province have fought a tough as well as a fierce battle. The so-called tough battle refers to our victory over the unprecedented serious drought, and the so-called fierce battle refers to the perilous, tense and arduous combat-drought struggle. Especially during the 70-80 day crop growing period in which there was no saturating rain, the masses were in an anxious state of mind. Some places made preparations against natural disasters for a time. Nevertheless, the party's policies aroused the people's enthusiasm to overcome natural disasters and to wrest a good harvest.

Some comrades said: This year, we first felt pleased to see that the spring rain benefited the growth of seedlings, then worried about the insufficient saturating rain during the 70-80 day summer and autumn period and finally felt pleased again with the long, frostless period which resulted in a good harvest of hills and hills of food expected that is we never expected that all seedlings would benefit by the spring rain; that such a serious drought would occur in summer and autumn; and that we would reap such a good harvest in the autumn. This shows that we have gone through a very complicated situation. Indeed, it is a miracle to wrest a bumper harvest in a year of serious drought. We need to sum up the experiences in performing this miracle.

Some people said that heaven helped them and that the good weather in the late stage of the crop growing period resulted in this bumper harvest. Some people also said that they had effective measures for increasing this year's agricultural production. Such views are all definitely reasonable. However, they have not pinpointed the essence of the issue. We should see through the appearance to the essence. The fundamental reason for this year's bumper harvest despite the serious drought is the power of the party's policies and the implementation of the guiding principles of the central authorities and the provincial CPC committee on further emancipating thinking, the bold implementation of the production responsibility systems in line with the desires of the masses and the relaxation of the restrictions on the masses so as to give full rein to the potentially immeasurable socialist enthusiasm, the wisdom and talent of the masses. This inexhaustible power has created the miracle of wresting a bumper harvest in a year of serious drought.

Why do we have the three unexpected things? It is because our understanding lagged behind the practical situation. We have noticed or only paid attention to serious drought and neglected the power of the party's policies. We have also underestimated the masses' socialist enthusiasm aroused by the party's policies. Some people said that heaven helped them. This is not correct, because this year heaven actually did not give much help during the crop growing period. We had 200 millimeters less rainfall than in normal years during the crop growing period; we experienced no floods during the flooding season and no rain during the rainy season. If we did not have the production responsibility systems to arouse the commune members' enthusiasm to combat drought, to protect seedlings and to wrest a bumper harvest, how could heaven create food grain while we could not even ensure the full growth of seedlings.

What the masses say is good. The people's efforts together with the help of the heaven and the policies have brought about this bumper harvest. Policies are the fundamental reason for this success. If we did not have the production responsibility systems, the people would not have enthusiasm, nor could heaven render any help.

Some commune members said that the implementation of the production responsibility system is another great liberation of the production force after the land reform. This is very reasonable. We must realistically sum up this year's tense, tortuous and rich struggle experience, enhance our understanding of policies and the party's mass line, further strengthen our consciousness of the earnest implementation of the party's policies, persist in relying on the masses, and better research and formulate plans for next year and for the days to come so as to create a new situation in our province's agricultural development.

Comrade Qiang Xiaochu urged all localities, while holding training classes for party members and cadres this winter and next spring, to take the 12th CPC Congress guidelines as weapons for earnestly summing up the experiences gained in the work this year and to conduct mass discussions and summations on the experiences.

He emphatically noted: To sum up the experiences is aimed at further enforcing and bringing into full play the tremendous role of various production responsibility systems that have been suitable to local conditions. He stated: The people are the masters of history and the true heroes. As Comrade Stalin said it well, ordinary people are often closer than high echelon officials to the truth. We, therefore, should fully trust and rely on the masses and boldly hand over to them the decisive right of selecting responsibility systems. This means that the masses should be allowed to chose their own responsibility system according to the practical effectiveness of the system. Leading cadres should refrain from being prejudiced, setting up rigid rules and seeking uniformity in doing everything. This means that each responsibility system to be enacted should be exactly suitable to local conditions, should be an incentive to greater output and should be welcomed by the masses. It is necessary that it be clear that each responsibility system is legal and of a socialist character.

Comrade Qiang Xiaochu called on all leading cadres to actively go into action and go deep among the masses, and through investigations and studies, to accurately discern the people's desires, to support the people's correct demands and to guide or encourage the people to become wealthy through labor. In implementing production responsibility system, leading cadres should give the people a free hand in their work but refrain from letting any deviations made in implementing the systems unchecked. This means that we should give the people a free hand in selecting their responsibility system and respect the people's opinions, but that we should not let the slightest deviation be made in exacting responsibility systems unchecked. Efforts should be made to strengthen leadership over the work and carry out the work in a down-to-earth manner.

Comrade Qiang Xiaochu pointed out: It is totally wrong to say that the party branch is of no use when a responsibility system of assigning farm output quotas for individual households has been enacted. As a matter of fact, the party branch should make further efforts to conduct guidance in every household following the enactment of production responsibility systems. This means that, following the enactment of responsibility systems, the duty of cadres is heavier, more complicated and more painstaking than before. In the past, the party branch just dealt with large groups of people because they, as a group, started a day's work when the bell rang, attended meetings to have their work appraised and did their work in a massive, unplanned manner. At present, the party branch, however, should deal with specific production teams, work groups households and individuals, as well as with every production link.

Our cadres should see their heavy duties and be full of enthusiasm and the spirit of being responsible for the party and the people to enhance their leadership over the work to enact various responsibility systems. They should help every production team, work group and household in making preparations in various areas, such as grain strains, chemical fertilizer, agricultural chemicals, animals, production tools, food grain and fodder, and in making arrangements for various production links, such as farming preparations, spring sowing, summer hoeing, autumn harvesting and distribution.

Comrade Qiang Xiaochu urged cadres across the province to work together with the masses while studying and implementing the 12th CPC Congress guidelines, to grasp well the current work, to make good arrangements for the 1983 work and to map out long-term plans for quadrupling agricultural output value. He stated: Current tasks for rural areas are to vigorously thresh crops, deliver grain to granaries and to conduct autumn distribution. Then, rural areas should hold rotation training classes in a planned manner to educate party members and cadres in an effort to achieve the enhancement of leading bodies and grassroots work. Attention should be paid to studying and solving new problems existing in the new situation of enacting responsibility systems. For example, our province has less farmland, and its per capita acreage of farmland is only 3 mu. The province, however, has over 120 million mu of land suitable for planting trees and over 40 million mu of grassland and land suitable for herding animals. If we fail to get rid of the rigid principle of taking grain production as our main task and concentrate on this task only, we will hardly become wealthy. To become wealthy, we simply must follow the principle of engaging in a diversified economy and conducting comprehensive development by combining farming, forestry, animal husbandry, side-occupations and fisheries, as well as conducting comprehensive development of industry, agriculture and commerce. All of this requires leading cadres to stand on a higher place to get a far-reaching view and to refrain from concentrating only on grain production. While doing a good job in grasping grain production, leading cadres should accurately understand their local conditions to develop their strong points and to strive to achieve rapid development in mountainous and aquatic production.

Only by fully utilizing our province's natural resources and developing the rural economy in an all-round way, particularly by opening more avenues for domestic side-occupations and developing a diversified economy, will we be able to quadruple the agricultural output value at the end of this century and to attain a well-to-do standard of commune member livelihood.

RURAL CADRES URGED TO IMPROVE RESPONSIBILITY SYSTEM

SK030347 Changchun Jilin Provincial Service in Mandarin 1100 GMT 2 Dec 82

[Station commentary: "Do Not Wait and See, Vigorously Readjust and Improve the Responsibility System"]

[Text] Many localities in our province are currently deliberating or conducting the work of readjusting and improving the production responsibility system. Party committees at all levels have included the work in their work schedule. However, some brigade or production team cadres are still taking a wait-and-see approach. Commune members say that brigade cadres are waiting to collect the systems others have improved, production team cadres are waiting to select one from the collected systems and work group leaders are waiting to implement the selected ones. Such a passive attitude, if not corrected, is bound to adversely influence the readjustment and improvement of the production responsibility system. Leading persons at all levels should pay attention to this and conscientiously work out ways to solve it. The production team cadres' wait-and-see attitude mainly arises from their misunderstanding of the system of allotting work to individual households, which they think is a kind of individual farming divorced from the collective. All party organizations should intensify the education on policies to enable cadres who have such a misunderstanding to further understand that allotting work to individual households is a form of the production responsibility system of the socialist collective economy. They should see that the contracted households should at once have decisionmaking right in management and subject themselves to the guidance of the state plan and the unified management of production teams. After institution of the system, not only production teams cadres, who are to take charge of the managerial work, but also corresponding and more scientific managerial work are needed. It is hoped that production team cadres will adapt themselves to the new situation emerging after the institution of the responsibility system, study new conditions and solve new problems so as to take the lead in readjusting and improving the production responsibility system and in creating a new situation in production.

RURAL WORK CONFERENCE HELD

SK050217 Changchun Jilin Provincial Service in Mandarin 1100 GMT 4 Dec 82

[Text] According to our sources, the provincial CPC committee held a provincial rural work conference in Changchun on 4 December. Comrade Mu Lin, Standing Committee member of the provincial CPC committee, presided over the conference. Comrade Zhang Shiying, secretary of the provincial CPC committee, relayed the guidelines of the national conference on rural political and ideological work and the meeting of agricultural secretaries of CPC committees in various provinces, municipalities and autonomous regions. Attending the conference were agricultural secretaries of CPC committees, directors of agricultural and industrial departments and heads of propaganda departments of various municipalities, prefectures and autonomous prefectures. Also attending were agricultural secretaries of various county CPC committees and responsible persons of departments concerned directly under the provincial people's government.

Comrade Mu Lin said at today's conference: The tasks of this conference are to comprehensively implement the guidelines of the national conference on rural political and ideological work and the meeting of agricultural secretaries of CPC committees in various provinces, municipalities and autonomous regions; to conscientiously sum up our province's experiences gained in rural work since the Third Plenary Session of the 11th Party Central Committee; to unify our understanding and emancipate our thinking; to discuss and define the strategic goals for our province's agricultural development and the tasks for the 1983 production; to discuss the issues concerning the readjustment, improvement and development of the agricultural responsibility systems, the transformation of rural systems and the relaxation of policies; to discuss the issues on strengthening and improving party leadership and rural political and ideological work; to further implement the guidelines of the 12th Party Congress; and to carry forward the new achievements in agriculture so as to achieve success in building our province's socialist material and spiritual civilizations.

BRIEFS

GRAIN HARVEST--This year, Jilin Province's Tonghua Prefecture saw a rich agricultural harvest. As of 28 November, the prefecture overfulfilled its annual grain procurement task of 500 million jin by 60,000 jin. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 2 Dec 82 SK] Yanbian Korean Nationality Autonomous Prefecture in Jilin Province reaped bumper agricultural harvests despite this year's natural calamity. This year the prefecture harvested 1.1 billion jin of grain, 25 percent higher than 1981, topping the highest level in history. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 2 Dec 82 SK]

BAICHENG PREFECTURE GRAIN PROCUREMENT--Baicheng Prefecture, in Jilin Province, which has suffered serious natural disasters, had put 508.32 million jin of grain in storage by the end of November, overfulfilling the annual procurement plan by 13 percent. [Changchun Jilin Provincial Service in Mandarin 1100 GMT [date not given]]

SIPENG PREFECTURE GRAIN OUTPUT--Siping Prefecture, Jilin Province, is expected to reap 5.5 billion jin of grain and soybeans, in 1982, an increase of 2 percent over 1981. The peasants in this prefecture attributed the bumper harvest to the implementation of production responsibility systems. Production teams implementing the double contracting system account for 72 percent of the prefecture's total. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 22 Nov 82 SK] In Jilin Province, Siping Prefecture had stored 1.82 billion jin of grain by 26 November and Changchun Municipality had stored 1,497 million jin by 25 November, both overfulfilling their grain procurement targets. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 27 Nov 82 SK]

JILIN MUNICIPALITY GRAIN PROCUREMENT--As of 18 November, Jilin Province's Jilin Municipality sold 600,230,000 jin of grain to the state, overfulfilling its annual grain procurement task. The municipality sold 264.12 million jin of paddy rice to the state, overfulfilling its procurement plan by 1.6 percent and accounting for 43.3 percent of the province's total. It sold 119.79 million jin of soybeans to the state, overfulfilling the soybean procurement plan by 33.1 percent. [SK210032 Changchun Jilin Provincial Service in Mandarin 2200 GMT 19 Nov 82 SK]

PADDY RICE PRODUCTION--As of 24 November, Jilin Province had stored 713.57 million jin of paddy rice, overfulfilling the annual procurement target by 18.9 percent. More than 90 percent of the paddy rice was of the first quality. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 27 Nov 82 SK]

FOREST OWNERSHIP--By September Jilin Province had fixed the ownership of 10.36 million mu of mountains and forests, accounting for 85.3 percent of the mountains and forests whose ownership was to be fixed, assigned 1,735,000 mu of mountains and forests to communes in forestry areas who had no forests and allocated 542,000 mu of privately owned mountainous areas to 75,000 households. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 27 Nov 82 SK]

SOYBEAN HARVEST--Jilin Province has reaped a bumper soybean harvest in 1982. As of 11 November, Jilin Municipality had stored 106.6 million jin of soybeans, overfulfilling the task by 21 percent. Tonghua Prefecture has stored 62.93 million jin, 4.9 percent above plan. Yanbian Korean Autonomous Prefecture had stored 92.35 million jin, overfulfilling the assigned quota by 15.4 percent. [Changchun Jilin Provincial Service in Mandarin 1100 GMT 21 Nov 82 SK]

COMMENTARY ON RESPONSIBILITY SYSTEM

SK170846 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 16, 18, 22 Nov 82

[16 Nov 82]

[Station's fourth commentary on the system of fixing output quotas on households and the system of peasant households assuming full responsibility for task completion, entitled: "Letting Peasant Households Assume Full Responsibility for Task Completion Will Further Reflect the Principle of To Each According to His Work"]

[Text] Some people worry that the socialist principle of to each according to his work will be changed along with the instituting of the system of peasant households assuming full responsibility for task completion. It is just the opposite. The system will further reflect this principle. As everybody knows, in the socialist principle of to each according to his work, distribution is based on the amount and quality of work done by every member in society for developing the national economy. In the system of peasant households assuming full responsibility for task completion, the principle for distribution of products is that quotas to be turned over to the state are fulfilled first, then sufficient supplies are retained for collective use, and finally the rest belongs to individuals. This takes into account the interests of the state, collectives and commune members. In the meantime, because the form of distribution has changed from distribution according to workpoints to distribution according to prescribed production output, the equalitarianism of eating out of the common pot has been overcome and the principle of to each according to his work and more pay for more work has been reflected.

Our collective economy has followed the Soviet system of collective farms to a great extent. In distribution, the workpoint system has been implemented. Because these systems have been adopted for a relatively long period of time, the people consider them as fixed models of socialist agriculture. Many years of practice have shown that workpoints can only measure how long one works but not the amount of labor and, therefore, cannot represent the socialist form of distribution. They are not the only way to implement the principle of to each according to his work.

Contracts are the core of the system of peasant households assuming full responsibility for task completion. The form of distribution is making payments in accordance with production output. Remuneration is based on the prescribed production output. Above-quota remuneration should be given for above-quota output. Compared with the form of assigning payment in accordance with workpoints, the form of assigning payment in accordance with production output more fully embodies the principle of to each according to his work. Because the system of peasant households assuming full responsibility for task completion can further reflect the socialist principle of to each according to his work, it makes every laborer concerned with his work results in light of personal material interests. Peasants can arrange and plan their production items in line with their capacity and speciality and throw all their energy into their production. By so doing, the initiative of every member of a household--including men, women, the old and the young--will be mobilized. Therefore, it is a strong force to promote production.

Noticeable changes have been made in production in those places which have implemented the system of peasant households assuming full responsibility for task completion. In some places, their production has doubled and redoubled. Peasants have happily said: With the implementation of this system, financial resources have been broadened and agriculture, forestry, animal husbandry, sideline production and fishery have become prosperous. A happy situation has descended upon the impoverished production teams. In rich production teams, flowers have been added to the brocade. All these facts indicate that the system of peasant households assuming full responsibility for task completion is a new key in changing poverty to riches and is a thoroughfare to develop agriculture production. Therefore, we should emancipate our thinking, eliminate the left influence, take our own roads and build a modernized agriculture imbued with Chinese characteristics. The implementation of the system of peasant households assuming full responsibility for task completion is an important part in building a modernized agriculture imbued with Chinese characteristics.

[18 Nov 82]

[Station's fifth commentary on the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion, entitled: "Correctly Understand the Peasants"]

[Excerpts] (Chen Baohua's) family, a household that contracts for crop farming in (Qijiazi) brigade in Xinmin County's (Sandaogangzi) commune, has sold more than 55,000 jin of grain to the state, overfulfilling the prescribed quota by 46,000 jin. Prior to the sale, someone told him that he could get 2,000 yuan more at the market price than by selling his grain to the state. However, (Chen) firmly said: Even if the market price is higher, I will market my grain to the state.

(Chen's) thinking and behavior demonstrates the tremendous socialist enthusiasm of the peasants in our province after having instituted the responsibility system in production. This is the main trend of ideology and political sense of the peasants in the 1980's.

At present, many comrades underestimate the thinking of peasants. Some people have said, for instance: With more money in their hands, today's peasants are more selfish. Having implemented the responsibility system, peasants only take into account their personal interests and neglect the collectives'. Whenever they speak of the peasants, they refer to them as selfish, narrowminded, conservative, ignorant and backward. Lenin's judgment on individual peasants made in the Soviet Union's early period of economic policies and expressed in his statement that small-scale production is a constant, day-to-day force and is a tendency of capitalism and the bourgeoisie has become an invariable theoretical basis used by these comrades in understanding peasants. The reason these comrades have such wrong ideas is that they always approach today's problems with yesterday's visions and they have failed to completely free themselves from the yoke of leftist ideology.

We should see that today's peasants are basically different in various respects from those in the early post-liberation period. Through the socialist transformation, our country's rural areas have carried out the cooperative movement and eliminated the exploiting class. Peasants are closely integrated with the destiny of our socialist motherland. They have broken through the limits of narrowmindedness and of small producers and widened their fields of vision. Since the Third Plenary Session of the 11th Party Central Committee, the broad masses of peasants, under the guidance of the party's line and principles, have given full play to their role involving initiative and enthusiasm. They have continually made new contributions to creating a new socialist life.

In the meantime, we should notice that many peasants today have been corroded by the influence of feudalist and bourgeois ideology and have been affected to a certain extent by the pernicious influence of anarchism and ultra-individualism in the 10 years of turmoil. A negative situation still exists in a few people. This shows that we should strengthen ideological and political work among the peasants. However, we should by no means negate the progress made by the peasants in the past few decades under the party's education, let alone attribute all these consequences to the instituting of the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion and, therefore, be skeptical about the correctness of the rural economic policies formulated since the Third Plenary Session of the 11th Party Central Committee. Only by so doing can we stay sober-minded in readjusting the rural production relations and in reforming the system of economic administration.

[22 Nov 82]

[Seventh station commentary on the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion, entitled: "The System of Fixing Output Quotas Based on Households and the System of Peasant Households Assuming Full Responsibility for Task Completion Are Not Expedient Measures"]

[Text] At present, while implementing the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion, some comrades say: Do not fool around, these systems will be changed before long. These comrades regard the responsibility system as a bad interim measure and a stopgap.

We think that the system of fixing output quotas based on households and, in particular, the system of peasant households assuming full responsibility for task completion are great creations of China's peasants, proceeding from the reality of rural areas and implementing the policies formulated by the Third Plenary Session of the 11th Party Central Committee. They are relatively good forms of the responsibility system for managing and administering our country's socialist agriculture in the present period. Compared with other forms of the responsibility system, these two are most connected with the peasants' material interests. The assignment of responsibility in these two forms are most specific and their distribution methods are the simpliest. They are suitable for natural conditions and economic development levels in most rural areas. They are important managerial and administrative forms which have been gradually established, through repeated comparisons and selections, by the broad masses of peasants in the course of the protracted collectivization of agriculture. Meanwhile, these two forms have become the major ones in rural areas throughout the country. On the basis of this, how can we say these forms are the worst ones? On the contrary, they should be adopted for a long period of time.

Viewed from the experiences and lessons gained in our country's economic development, all major economic reforms need a relatively long time to become stabilized. If we make changes every 2 or 3 days, peasants will not feel steady and sure and will certainly be skeptical about the stability of policies. In this case, how can they keep their minds on their production? Since the cooperative transformation of agriculture, peasants have suffered a [word indistinct] physically and mentally. In communes and brigades implementing the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion, peasants most worry about returning to the old path--eating out of the big communal pot--or returning to other forms which they do not welcome. Therefore, we should not go against the will of peasants, let alone cook up the wrong idea that these two forms of the responsibility system will not last for a long time and will be changed.

We should also see that the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion were introduced in the province just 1 or 2 years ago. However, practice has fully proved that these two forms of the responsibility system have great vitality and superiority. In the meantime, we should see that because these two forms of the responsibility system were introduced not long ago and we have had little experience in this regard, there have been some problems in the course of implementation. For instance, how do we properly handle the relations between unified management and the division of labor? How do we manage and use draft animals and farm tools? How do we make proper arrangements for surplus labor forces? These problems cannot be solved in one morning or evening. To solve these problems, peasants' efforts are needed and a relatively long time should be taken.

In his report to the 12th Party Congress, Comrade Hu Yaobang pointed out: The responsibility system for production set up in various forms in the countryside has further emancipated the production forces and it must be adhered to for a long time to come. The thing for us to do is to gradually perfect it on the basis of summing up the practical experience of the masses. In no case must we make rash changes against the will of the masses. With such clear instructions from the party Central Committee, how can we worry about the protracted nature of the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion? Of course, changes will occur with anything. In the future, when the rural production forces are highly developed, new organizational forms will certainly emerge to suit this situation. This is a necessary law of development of things. What kinds of responsibility system in production will be developed in the future? It depends on the will and choice of the peasants. In other words, we would let peasants themselves create the form instead of following the rigid rules of the higher authorities. Above all, we should on no account backtrack.

CSO: 4007/67

DEVELOPMENT OF MOUNTAINOUS AREAS REPORTED

SK241249 Shenyang LIAONING RIBAO in Chinese 8 Nov 82 p 1

[Excerpt] In the course of studying the documents of the 12th Party Congress, the Jianping County CPC Committee, in line with the reality of the county and the present situation in sending relief to disaster areas, decided to apply the experiences they have gained in implementing the system of signing comprehensive contracts for fixed quotas to manage farmlands, which amount to 20 percent of the county's total areas, to management of mountainous areas, which amount to 70 percent of the county's total, so as to fulfill the long-range plan for wealth and make new progress in building mountainous areas.

Jianping County is a mountainous region with a vast territory but sparse population. Since this spring, over 90 percent of communes and brigades have implemented the "double contracting systems" and that has aroused the enthusiasm of the masses. Despite serious drought for 3 successive years, some communes and brigades have taken the "three-dependence" label off and the people of the county are calm and full of vitality.

In the course of studying and implementing the guidelines of the documents of the 12th Party Congress, the county CPC committee sent three investigation groups to Penghechuan, Linghechuan and Laohahechuan communes to conduct investigations. Summing up the experiences, they concluded that the policies of the party had tremendous force. The broad masses of commune members and grassroots cadres have drawn benefits from the "double contracting systems" and the potentials for production have been tapped and, as a result, the labor force and labor time showed surpluses. The system of signing contracts for fixed agricultural output quotas on 20 percent of the county's total areas no longer meets the masses' demands for eliminating poverty in order to prosper. So the masses eagerly demanded the expansion of the "double contracting systems" to develop the mountainous areas that account for 70 percent of the county's total area.

They held: It would be better to provide good policies than to provide money and food for the people. The "double contracting systems" has solved problems of food and clothing. The sooner we introduce the "double contracting systems" to further develop the mountainous areas, that account for 70 percent of the county's total areas, the earlier the mountains become green and the sooner the people become prosperous. This will greatly benefit the country and the people.

The county CPC committee firmly decided to formulate some provisional regulations on developing barren hills, waste ditches and waste beaches and some stipulations on signing contracts to develop collectively-owned mountain forests and grasslands.

On the premise of constant ownership systems and with regard to the interests of the state, collectives and individuals, the county CPC committee will sign contracts with commune members to develop barren hills, waste ditches and waste beaches and to take charge of some collectively-owned mountain forests and grasslands.

The regulations pointed out: The county government will issue licenses to households to manage private mountainous areas, beaches and ditches. The licenses will be effective for a long period of time and can be inherited. In accordance with demands for tackling problems in planned and comprehensive ways, commune members have the right of management. Commune members can market the timber and sideline products of private mountainous areas. Collectives will provide nursery stocks for commune members to develop barren hills. The collectively-owned mountain forests should implement various forms of responsibility systems such as systems of assigning fixed quotas to a group of households, individual households, and individuals and systems of signing contracts for fixed output quotas with teams, work groups and individuals engaged in specialized production. Various regulations on dividing mature timber have been stipulated.

COMMENTARY ON PROTECTING FARMLAND

SK150933 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 13 Nov 82

[Station commentary: "We Must Protect Arable Land"]

[Summary] Some communes and brigades in the suburban areas of Shenyang Municipality have engaged in the unhealthy practice of making over and lending arable land to other units in order to establish contacts. This kind of violation of state law must be strictly dealt with. Arable land is the means of production for developing agriculture. With the population increase and the development of all construction undertakings, the phenomena of wasting arable land are very serious in our province's urban and rural areas. The area of arable land is continuously decreasing. During the early period of the founding of China, the average per capita arable land for people in the province was 3.9 mu. By 1980, the average per capita arable land declined to 1.6 mu. If things go on like this, our province's agricultural production, other socialist undertakings and the livelihood of the people will be greatly affected. "Therefore, strengthening land management and strictly controlling the utilization of land in construction is one of the important issues in the current four modernizations drive. The utilization of land must be in line with the state stipulations and policies of the State Council and the province on land management. Rural communes and brigades are never permitted to trade arable land. Commune members only have the right to till private plots and contact responsibility plots. They do not have the right to own the land, and they even are not allowed to sell or to lease the farmland."

"It is hoped that all localities will adopt measures to protect arable land. In addition, all localities must step up investigations and deal with all violations of the state stipulations on land management in a timely manner."

CSO: 4007/67

REPORT ON BUILDING HOUSES ON FARMLANDS

SK260503 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 25 Nov 82

[Text] The provincial rural housing construction conference sponsored by the provincial CPC committee and government concluded in Tieling 22 November. The conference urged: Currently efforts should be made to attend to propaganda and education, work out plans for rural housing construction and immediately stop unplanned housing construction and unauthorized occupation of farmlands.

Since the Third Plenary Session of the party, the masses of peasants have improved their living standards and built many houses on the basis of developed production. However, a phenomenon of unplanned housing construction and unauthorized occupation of farmlands has also appeared. The phenomenon is grave in some areas.

The conference urged: We must enhance our understanding and approach from the perspective of national policies the task of valuing every inch of land. We should educate the cadres and people to link immediate interests with long-term interests and never foster the idea that building more houses on farmlands means "showing concern for the masses." If we build houses on farmlands, farmland will be reduced more and more and we will unavoidably hand trouble to later generations and make historical mistakes. The cadres and people should conscientiously study relevant laws and regulations of the state and the province and resolutely stop the evil trend of arbitrary occupation of farmlands.

The conference called on efforts to immediately organize personnel to go to grassroots units to investigate the problem of unplanned housing construction and unauthorized occupation of farmlands, particularly to investigate leading cadres and party-member cadres with such problems, and to strictly handle the incidents in violation of policies, laws and decrees.

PEASANT EDUCATION MEETING ENDS

SK131158 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 12 Nov 82

[Text] According to our reporter, a 4-day provincial experience exchange meeting on peasant education concluded in Shenyang on the afternoon of 12 November. The meeting summed up and exchanged experience on leadership, management and basic teaching of peasant education and discussed ways to improve peasant educational work in line with the gratifying situation in rural areas which has resulted from the implementation of the responsibility system in agricultural production.

Along with the implementation and perfecting of responsibility systems in production, an upsurge in studying scientific knowledge has begun in our province's rural areas. Education on technical know-how has been promptly developed and that on cultural knowledge has been in the ascendant. A new situation--a combination of political, cultural and technical education, a combination of popularization and improvement and the simultaneous development of varied teaching forms--is taking shape in our province's peasant education. More than 700,000 people are receiving such education.

Although our province has scored great achievements in peasant education, viewed from a practical standpoint, peasants' educational and scientific levels are still low, far from meeting the demands of agricultural modernization and rapid agricultural development. This has demonstrated the urgency of popularizing and enhancing education on agricultural and scientific knowledge among the broad masses of peasants. The meeting also put forward some specific measures to enhance peasants' educational and scientific levels and exchanged some experiences. At the conclusion, deputy governor Zhao Qi attended and addressed the meeting.

CSO: 4007/67

BRIEFS

COTTON OUTPUT--Liaoning Province had purchased 350,000 dan of ginned cotton as of 12 November, fulfilling its annual procurement plan. The province's ginned cotton output is estimated at 440,000 dan, topping the 1981 figure by 25,000 dan. Procurement work is continuing. [Shenyang LIAONING RIBAO in Chinese 14 Nov 82 p 1 SK]

GRAIN OUTPUT--Shenyang Municipality, Liaoning Province, has achieved a record grain and soybean output in a year of serious drought. The total output of grain and soybean is 3,205,000,000 jin, surpassing the previous record output in 1980 by 55 million jin. [Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 2 Dec 82 SK]

LIAOYUAN MUNICIPALITY SOYBEAN PRODUCTION--In Liaoning Province, Liaoyuan Municipality had procured 29.58 million jin of soybeans by 1 November, overfulfilling its annual soybean procurement task by 330,000 jin. [SK051022 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 4 Nov 82 SK]

LOW AGROTECHNICAL STANDARD--The great importance of relying on science and technology to develop agriculture is being recognized by more and more people. In particular, since the institution of the production responsibility system, the masses have become very eager to master scientific farming technology. However, our province's current agrotechnical capacity and level of technical guidance lag far behind the needs in agricultural development. According to statistics, every one of our agrotechnical cadre is responsible for giving technical guidance for some 9,000 mu of farmland. In some counties and areas, there is only one agrotechnician for every 5,000 peasants. For this reason, training agrotechnical cadres and developing the people's abilities and wisdom have become an extremely urgent task for promoting agriculture. The vast rural areas are presently in the midst of a new, great period of changes. Agricultural broadcasting schools meet the rural needs in their new changes. They provide timely help, gear their work to the urgent needs of peasants, improve service and regard the work of the masses of peasants as their own. Their ideas and workstyle are worth emulation by other units. [Text] [SK010348 Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 30 Nov 82]

COTTON PROCUREMENT--As of 15 November Liaoning Province had procured 364,700 dan of cotton, overfulfilling the state plan by 4.2 percent and registering an increase of 1,600 dan over the 1981 figure. [Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 17 Nov 82 SK]

SOYBEAN PROCUREMENT--As of 10 November, Liaoning Province's Tieling Prefecture sold 130.95 million jin of soybeans to the state, overfulfilling its annual soybean procurement plan by 0.7 percent. Of the total, 84.8 percent are top-quality soybeans. [SK210036 Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 18 Nov 82 SK]

GRAIN PROCUREMENT--Liaoning Province had purchased and stored up 2.26 billion jin of grain and oil-bearing crops as of 6 November, fulfilling 36 percent of the state procurement plan and storing up 400 million jin more than the corresponding 1981 period. Xinbin and Qingyuan counties have fulfilled their procurement tasks. The provincial grain bureau recently pointed out the following problems in grain procurement: 1) Some municipalities, counties and districts have not paid enough attention to grain procurement and work in this regard progressed slowly. 2) Some organizations, PLA units and enterprises have gone to the countryside to purchase grains and oil-bearing crops despite the state guidance to the contrary. Some small retailers have purchased grains and oil-bearing crops in the countryside and resold them at a profit, obstructing state procurement. 3) Inadequate power supply in the countryside has hampered the threshing of grains. 4) Some grassroots grain depots failed to make adequate preparations for procurement. [Shenyang Liaoning Provincial Service in Mandarin 2200 GMT 17 Nov 82 SK]

CROP PROCUREMENT--To date Liaoning Province has procured 295,617 dan of ginned cotton and 364,464 dan of flue-cured tobacco, fulfilling the procurement plans by 84.5 and 72.9 percent, respectively. [Shenyang LIAONING RIBAO 31 Oct 82 SK]

LIAOYUANG MUNICIPALITY GRAIN PROCUREMENT--Liaoyang Municipality, Liaoning Province, has reaped the third bumper harvest in agriculture this year. The municipality is assigned to procure 440 million jin of grain in accordance with the state contract quota. By 9 November, grain departments in the municipality had procured 243 million jin of grain, 46.85 percent of the total and an increase of 88 million jin over the corresponding 1981 period. [Shenyang Liaoning Provincial Service in Mandarin 1100 GMT 16 Nov 82 SK]

AGRICULTURAL INCREASE--Since the third plenary session, Liaoning Province has reaped good harvests successively for many years. Compared with 1978, its 1979 and 1980 grain output were 6.9 and 9.4 percent higher, respectively. Its 1981 grain and soybean output was the third highest since the founding of the PRC. It achieved an annual increase of 42.7 percent in the output of oil-bearing crops since the third plenum. In 1981, its cotton per-mu yield increased from 31 to 75 jin and its tussah cocoon output reached 905,000 dan. [Shenyang LIAONING RIBAO in Chinese 19 Oct 82 p 1 SK]

AUTUMN AFFORESTATION--By the end of September, Liaoning Province has afforested 771,000 mu and leveled 1.33 million mu of forest land. [Shenyang LIAONING RIBAO in Chinese 11 Nov 82 p 1 SK]

AGRICULTURAL PRODUCTION--Fengcheng County, Liaoning Province, has reaped a bumper harvest this year. Among the 2,172 brigades in the county, 1,567--72 percent--have implemented the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion. Although hit by serious floods, droughts, strong winds and other natural disasters, total grain output increased 19 percent over 1981. This year each peasant owns 700 jin of grain. Total agricultural income increased by 5 million yuan over 1981. Per capita income of commune members will reach 350 yuan, up 72 yuan over 1981. END TO FOREST DESTRUCTION URGED

SK021023 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 1 Dec 82

[Text] Recently, the regional people's government held a forum in Hohhot Municipality to implement the emergency directive of the CPC Central Committee and the State Council on stopping the destructive felling of trees.

The forum summed up experiences of all localities in stopping the evil practice of forest destruction and made plans for comprehensively accomplishing "three-fixed" forestry work, for conscientiously implementing the principles of the individual, collective and state planting trees simultaneously and for implementing the responsibility system of assigning tasks on a household basis among collective-owned forests.

The forum held: Our region has entered a new stage of developing forestry production and construction. By mid-November the region afforested over 7.9 million mu, setting the highest annual record, and there was a marked decline in the trend of destroying forests. Especially since implementing the emergency directive of the CPC Central Committee and the State Council on stopping the destructive felling of trees, all leagues and municipalities have taken immediate measures to go into action, and banners and counties have organized inspection groups to handle cases of forest destruction in a strict and timely manner and to deal blows at the criminal activity of destroying forests. At present, the region has basically stopped the evil practice of forest destruction.

The forum pointed out: We should thoroughly accomplish the "three-fixed" forestry work, stabilize fixed ownership of mountains and forests, delimit afforested areas among commune members and fix a responsibility system for forest production in the coming winter and spring. This is a basic measure of the CPC Central Committee and the State Council for protecting forests and developing forestry and a plan to last for generations for vigorously developing forestry.

Since last year, 31 banners and counties across the region have fulfilled the "three-fixed" forestry work. However, some localities only attended to fixing ownership and granting licenses to develop available wooded land but failed to delimit afforested areas among commune members and to formulate a responsibility system for forest production.

All localities should take the initiative in measures for firmly achieving the "three-fixed" forestry work.

The forum stressed: All forestry fronts should further emancipate their minds and soften their policies in order to implement the principles of the individual, collective and state planting trees simultaneously. The collective-owned forests should carry out the responsibility system of assigning tasks on a household basis.

In order to develop individual-owned forests, all localities must take swift measures for designating individual-owned afforested areas among commune members. Commune members should be given priority for planting trees in forests that are near villages and are good for management and afforestation.

The state and collectives should provide technical assistance, seeds and saplings for commune members and at the same time should focus on developing collective-owned afforested areas to bring the enthusiasm of the individual, collective and state into full play.

REGULATION ON GRASSLAND MANAGEMENT DISCUSSED

SK191042 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 18 Nov 82

[Text] In order to successfully manage, utilize, protect and build grasslands and solve the problem of an egalitarian way of using grasslands, the regional party committee recently gave notice to all leagues, municipalities, banners and counties urging them to implement the new grassland management regulation on a trial basis and pay close attention to the implementation in selected areas. The new grassland management regulation gives five explicit stipulations:

1. Grasslands are the basic means of production of animal husbandry, not wastelands. They are as important as farmlands for planting.

2. The ownership of the grasslands within the boundaries of this autonomous region is socialist ownership by the whole people, and socialist ownership by the collective for the present stage. The wild plant and animal resources of the grasslands, such as the water areas, forests and trees, reeds, [words indistinct] mushrooms and edible moss, belong to the units which own the grasslands unless they have been exceptionally assigned to be managed individually after approval by the people's governments at and above the banner or county level. The regional people's government authorizes the people's governments of all banner, counties, towns and suburban districts to issue grassland licenses. All units' ownership of grasslands is to be protected by this regulation from being encroached on by any other units or individuals. Units which own the grasslands may grant grassland utilization rights to grassroots production units and areas for grazing herds of livestock. The boundaries established at the time of liberation should be taken as the standard to define the boundaries between the communes within grasslands and those outside the grasslands. Boundaries established at the period of the cooperative movement should be taken as the standard to define the boundaries between communes within grasslands. Boundaries approved after legal procedures should be taken as the standard to define those between farms and production teams. Boundaries adjudicated according to law by the people's governments should be taken as the standard to define those of other categories. Unestablished boundaries should be decided on through discussions or adjudication. When deciding on the boundaries of grasslands, we should uphold the principles conducive to unity, animal husbandry and the interests of the minority people.

3. The policy of forbidding wasteland reclamation to protect livestock farms should be resolutely implemented and grassland reclamation should be strictly forbidden. Grasslands which should not have been reclaimed should be resolutely closed and afforested. Banner and county people's governments should fix reasonable grazing load according to the types of grasslands and their capacities so as to prevent grasslands from deteriorating and becoming sandy. As authorized by the central and regional authorities, all leagues, municipalities, banners and counties may designate in their own localities natural reservation areas to protect valuable, unusual and rare animal or plant resources or resources which have been seriously damaged and apply for an approval by the regional people's government. Any units or individuals should obtain approvals from the units which administer the grasslands and from the people's governments of banner, counties, towns and suburban districts before they lumber, gather or hunt in the grasslands. They should receive the supervision of local authorities, abide by law and discipline and pay grassland management fees according to regulations.

4. Units and individuals who distinguish themselves in conscientiously implementing this regulation and in grassland management, protection, utilization and construction should be encouraged morally and awarded materially. Those who violate the regulation should be criticized, educated or fined, should be made to pay compensation for economic losses, should have their illegally earned money or property confiscated or be investigated and be held responsible for the crimes in accordance with their offenses.

5. People's governments at all levels are responsible for implementing this regulation. They should authorize animal husbandry departments and grassland management departments to make arrangements for the implementation. League, municipal, banner and county people's governments may formulate detailed provisions for the implementation in line with the guidelines of the regulation and report to the regional people's congress standing committee for the record.

FURTHER RELAXING RESTRICTIONS URGED

SK021007 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 1 Dec 82

[Text] According to our reporter (Liu Xiechun), Jirem League, Nei Monggol Autonomous Region, has made continuous efforts to eliminate the leftist influence in order to relax policy restrictions to invigorate the economy. Since the Third Plenary Session of the 11th CPC Central Committee, the economic situation of the league has become better and better. Despite having had natural disasters last year and this year, its grain output is still equal to the figure of the last 4 years and its oil-bearing seed output has scored a large-scale increase. The league has also steadily upgraded its livestock output and has scored a 1 million mu increase each year in afforestation and a 20 yuan increase this year in its per capita income over the 1981 figures.

In line with the demands set forth by the 12th CPC Congress, however, the speed in developing agriculture in the league is not satisfactory. The party's various policies on the economy have not been thoroughly implemented by some areas and in some fields. There are still the rigid leftist rules fettering the people's thinking. Through summing up experiences and lessons gained in this regard, the league CPC committee contended that only by further eliminating leftist thinking can we create a new situation in economic construction. Therefore, the league CPC committee put forward the following five tasks in an effort to further relax policy restrictions:

1. Continuous efforts should be made to improve production responsibility systems. The large scale assignment of responsibilities to each household should be expanded to a larger degree in rural areas. In developing agriculture, livestock, industry, sideline occupations and others, such responsibility systems may be adopted or regarded as guiding principles.

2. Efforts should be made to change the situation of concentrating on one undertaking only. By adopting joint ventures and attracting personal investment it is necessary to organize the rural people to develop various transport and service businesses.

3. Efforts should be made to relax the restrictions on developing domestic sideline occupations among commune members, who should be allowed to personally buy tractors for production or transportation. Urban people and technical personnel should be allowed to sign contracts for specialized production in agricultural and pastoral areas. Skilled craftsmen should be permitted to open private businesses and to recruit their assistants and apprentices.

4. Efforts should be made to grant afforestation land as much as possible to commune members so long as they have ability and desire to plant more trees. Through bidding, contracts may be signed with commune members for planting trees and grass on waste mountains and for developing fishery in useless rivers and water areas.

5. It is necessary to allow collectives and individuals to run commercial firms. The state-run units in urban areas may allow their work groups, staff and workers to independently purchase or sell commodities and to render repair service in rural areas. It is also necessary to allow individual households to carry out such business operations in rural areas. After the fulfillment of the state's procurement plan, all indigenous and special products except for grains may be privately sold in markets outside the league and the region.

CSO: 4007/67

CIRCULAR DISCUSSES RESPONSIBILITY SYSTEMS

SK061024 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 5 Dec 82

[Text] On 30 November, the regional people's government issued an emergency circular on conscientiously grasping rural and pastoral work and urged all localities, in line with the guidelines of the 12th CPC Congress, to further sum up, perfect and implement various forms of production responsibility systems so as to apply scientific technology to develop agriculture, livestock farming and forestry and vigorously develop a diversified economy.

The emergency circular pointed out: Areas where the double contracting responsibility system is being implemented should not only focus on implementing systems of signing contracts to assume responsibility for certain cultivated land or certain production quotas, but should extend the contracting systems to various fields in a planned and step-by-step manner, such as developing forestry, barren hills, barren hillsides, water conservancy facilities, farming machinery, water areas, commune- and brigade-run enterprises, vegetable teams, and transport and service industries.

Collective economic units with higher unified management in which various systems of signing contracts for specialized production quotas are being implemented should improve the management of the collective economy to further eliminate egalitarianism in line with the wishes of the masses.

While giving full play to the advantages of unified management, we should pay attention to bringing into full play the system of signing contracts with households engaged in specialized production, household sideline production and some private sectors of the economy. We should never place excessive restrictions on commune members through unified management. Leading departments concerned should conscientiously help the masses consolidate, implement and perfect the responsibility system in line with the wishes of the masses.

Urgent efforts should be made to solve the problems of "everybody eating from the same big pot" in pastoral lands. We should fulfill the three-fixed forestry work in the coming winter and spring.

The circular stressed: From now on, we should focus on widely applying scientific technology in agriculture, livestock harvests. Departments of agriculture, animal husbandry and forestry at all levels throughout the region and scientific research units should organize forces to sort out all achievements in scientific research and to arrange them by categories. We should concentrate on widely popularizing those scientific research achievements that have been tested and proved to be noticeably beneficial to increasing agricultural, forestry and livestock production.

By popularizing the responsibility system of linking technology with output, scientific and technical personnel engaged in agriculture, livestock farming and forestry can concentrate on the development of production. From now on, we should assess, reward and provide material conditions for scientific and technical personnel in accordance with their achievements in applying technology and production.

Outstanding scientific and technical personnel should vigorously be promoted and be given excellent material conditions. The wage system should be based on scales. Those who accomplish nothing or score no achievements for several years should be transferred to other working posts.

The emergency circular of the regional people's government stressed: Efforts should be made to develop a diversified economy in order to increase the income of the broad masses of peasants and herdsmen and bring about prosperity as soon as possible.

Along with the development of animal husbandry, all localities should develop medium-sized and small feed-processing industries on a mass basis and make overall arrangements for those households engaged in specialized production in order to develop specialized production in rural and pastoral areas.

We should help specialized households and key households develop the diversified economy. We should provide funds and give material assistance to develop cropping, breeding and processing industries and general service trades. Specialized households and key households should work together with the broad masses of peasants and herdsmen to bring about prosperity.

NEI MONGGOL REPORTS RECORD LIVESTOCK INCREASE

OW091250 Beijing XINHUA in English 1141 GMT 9 Dec 82

[Text] Beijing, 9 Dec (XINHUA)--A record increase of more than 11.6 million head of livestock has been registered this year in Inner Mongolia Autonomous Region, north China.

This was disclosed by Wang Duo, secretary of the Inner Mongolia Regional Committee of the Chinese Communist Party, at panel discussions during the current session of the National People's Congress.

The achievement was scored in spite of serious drought and heavy snow, he said.

He said the number of livestock in the region now totals more than 47.21 million head. Fine-strain sheep accounts for 52 percent of the total number of sheep. The region has already overfulfilled the livestock purchasing plan of the state for the year.

Wang Duo attributed the achievement to the pursuance of a series of economic policies that suit the conditions of the region. They include:

--Readjusting the proportion between agriculture and animal husbandry by laying greater stress on the latter, raising the purchasing prices of some animal products, reducing or exempting taxes on animal husbandry for a certain period of time, thus greatly encouraging the peasants and herdsmen to develop animal husbandry.

--Introducing a responsibility system in production, expanding side-line occupations and restoring private plots, animals and grassland for peasants and herdsmen. Statistics show that private animals in the pastoral areas has reached 8.44 million head, or 30 percent of the total number of livestock in these areas.

--Strengthening pasture development. Last year, the region improved the conditions of more than 1.08 million hectares of natural grassland and stored up 3.3 million tons of grass, which has helped the animals tide over the bitter winter.

Inner Mongolia ranks first in the country in the area of grassland and the number of livestock. Thanks to the development of animal husbandry, the per capita income of the herdsmen in pastoral areas reached 360 yuan in 1981. More is expected this year.

Wang Duo is confident that living standards will continue to improve with state assistance as provided for in the new constitution and in Premier Zhao Ziyang's report on China's Sixth Five-Year Plan.

CSO: 4020/31

BRIEFS

AUTUMN AFFORESTATION--As of 8 November, Nei Monggol Region had afforested 1,219,000 mu, cultivated 5,400 mu of saplings, planted 2.47 million mu of trees in rural areas and leveled 300,000 mu of land for next year's afforestation. The proportion of per capita afforested area by commune members increased from 19.8 percent in spring to 25.8 percent in autumn. [SK150429 Hohhot Nei Monggol Regional Service in Mandarin 2300 GMT 13 Nov 82 SK]

ANIMAL-RAISING HOUSEHOLDS--Ju Ud League, Nei Monngol Autonomous Region, has scored marked achievements in developing livestock-raising households. As of early November 1982, the 11 counties and banners of the league had over 16,600 households that had signed a contract for raising specific livestock. [SK032349 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 1 Dec 82 SK]

GRAIN PROCUREMENT--As of 25 November, Hulun Buir League, Nei Monggol Region, had stored 318 million jin of grain and soybeans, overfulfilling the annual procurement tasks. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 30 Nov 82 SK]

XILIN GOL LEAGUE CROP STORAGE--As of 30 November, Xilin Gol League in Nei Monggol Autonomous Region had overfulfilled its grain and oil-bearing crops procurement plans by 2.5 and 20.5 percent respectively. By the end of November, the league had procured 34.82 million jin more of grain and 21.5 million jin more of oil-bearing crops than the corresponding 1981 period. [SK042253 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 2 Dec 82 SK]

BEET PROCUREMENT--As of early November, Nei Monggol Region procured 1.06 million tons of beets, topping the highest level in history. In 1982, the total beet output of our region is estimated to reach 1.1 million tons, a 30-percent increase over 1981. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 17 Nov 82 SK]

CROP STORAGE--Thanks to the institution of the responsibility system in production, Nei Monggol Region's total grain yield has set a record this year. By 15 November, the region had stored 1.3 billion jin of grain, an increase of 550 million jin over the corresponding 1981 period. Of them, 480 million jin were wheat and 530 million jin were oil-bearing seeds. [SK220134 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 20 Nov 82 SK]

BAYANNUR LEAGUE GRAIN PROCUREMENT--At present, Bayannur League of Nei Monggol Region has overfulfilled its annual grain procurement task by 1.3 percent. As of 15 November, the league sold over 248 million jin of grain to the state, more than an 80 million jin increase over the corresponding 1981 period. The league also procured 199 million jin of wheat, overfulfilling its procurement plan by 65.9 percent. [SK210111 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 18 Nov 82 SK]

ULANQAB LEAGUE GRAIN PROCUREMENT--Ulanqab League, Nei Monggol Region, overfulfilled its annual grain procurement task as of 12 November. This year the league's total grain output will reach 1.9 billion jin, up 10 percent over 1981. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 16 Nov 82 SK]

XILIN GOL LEAGUE OIL-BEARING CROPS--Xilin Gol League of Nei Monggol reaped a bumper harvest from its 518,000 mu of oil-bearing crops this year. The total output was 32.77 million jin, 150 percent more than 1981. So far the league has sold 13.63 million jin to the state, overfulfilling by 4.8 percent its procurement quota. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 10 Nov 82 SK]

XINGAN LEAGUE AFFORESTATION--Xingan League in Nei Monggol afforested 271,000 mu this year despite serious drought, overfulfilling by 14.6 percent the state-assigned annual afforestation quota. [SK120804 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 10 Nov 82 SK]

GRAIN OUTPUT--Thanks to the institution of the system of fixing output quotas based on households and the system of peasant households assuming full responsibility for task completion, Ju Ud League, Nei Monggol Region, has reaped bumper harvests in all crops this year. Total grain output has increased to 2.2 billion jin this year as against 1.7 billion jin in 1981. In addition, over 92 percent of production teams in the league have implemented the above-mentioned responsibility systems. [SK270235 Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 24 Nov 82 SK]

HOHHOT MUNICIPALITY AGRICULTURE--Hohhot Municipality, Nei Monggol Region, has overfulfilled the annual procurement tasks for grain and oil-bearing crops. As of 21 November, the municipality stored up 61.07 million jin of grain, up 18.5 percent over the corresponding 1981 period, and 6.23 million jin of oil-bearing crops, up 58.9 percent. [Hohhot Nei Monggol Regional Service in Mandarin 1100 GMT 24 Nov 82 SK]

NEI MONGGOL SUGAR BEET--Hohhot, 29 Oct (XINHUA)--Nineteen sugar refineries in China's Inner Mongolia Autonomous REgion have started production and expect to have a record beet sugar output of 120,-00 tons, 20 percent more than in the last sugar refining season, local authorities reported. This year's output of beets from 66,600 hectares planted to the crop is more than 1 million tons. The output is the highest in the 30 years of beet growing in Inner Mongolia, one of China's major beet sugar producers. The People's Government of Inner Mongolia allocated 80 million yuan to expand and transform sugar refineries in the region. Thus the daily capacity of refining beet has risen from 7,000 tons to 10,000 tons. The beet output was only 380,000 tons in 1978. [Text] [OW301433 Beijing XINHUA in English 0713 GMT 29 Oct 82]

NEI MONGGOL DAIRY PRODUCTION--Hohhot, 30 Oct (XINHUA)--Dairy farms in the Inner Mongolia Autonomous Region turned out 7,600 tons of dairy products in 1982's first 9 months, 50 percent more than the same 1981 period, according to the regional government. The local government has over the past few years encouraged individual herdsmen and collective farms to raise more milch cows by providing interest-free loans and subsidized concentrated feed. This has led to a big increase of cows. Today farmers in the Hulun Buir League alone own 22,000 cows. Fresh milk sold to the state by individual herdsmen and peasants accounted for over 50 percent of the league's total. More creameries in the region have been expanded and revamped to meet the increased milk output and raise the quality of the dairy products. In the first 4 months of this year, fine quality milk, cream, lactose and casein took up 95 percent of the regional total production. [Text] [Beijing XINHUA in English 1300 ,MT 30 Oct 82 OW]

CSO: 4020/31

BRIEFS

BEET, SILKWORM PRODUCTION--Beijing, 25 Nov (XINHUA)--A record beet harvest of 150,000 tons was reaped in Ningxia Hui Autonomous Region this year, an increase of 2.5 times over last year, according to the regional agricultural department. The region expanded areas grown to sugar beet from nearly 3,000 hectares to about 8,500 hectares and also provided improved seed varieties for the peasants. Agrotechnicians helped by giving advice on scientific farming. Jiangsu Province has harvested 45,500 tons of silkworm cocoons this year, 13 percent more than last year, the provincial agricultural department said. Jiangsu, one of China's major cocoon producers, this year increased mulberry farms by 18,600 hectares. [Text] [Beijing XINHUA in English 1121 GMT 25 Nov 82 OW]

MEETING ON DEVELOPING ANIMAL HUSBANDRY HELD

HK240719 Xining Qinghai Provincial Service in Mandarin 1100 GMT 23 Nov 82

[Summary] An 8-day meeting held by the Qinghai Provincial People's Government for heads of prefectures and counties in pastoral areas ended in Xining on 20 November. Comrade Song Lin, deputy secretary of the provincial CPC committee and vice governor of the province spoke at the meeting. Vice Governor Comrade Ga Bulong delivered a report on developing animal husbandry at a good pace. During the meeting, leading comrades of the provincial CPC committee listened to reports and made directives on seven issues, namely the study of the 12th Party Congress documents, work style, production responsibility system in livestock breeding, the building of grasslands, evolving new breeds, cadres and religion.

The meeting pointed out: "Since the 3d Plenary Session, the general situation in pastoral areas is good, but the pastoral industry in our province is still in a state of slow development, low standard and instability. Compared with the pastoral areas in other provinces, we lag far behind in the obtaining of better economic returns. The reason is that not much improvement has been made in production conditions and ranges are not well managed and maintained and have even been badly damaged. If no prompt improvement is made in production conditions and the building of ranges, then neither the quantity nor the quality of livestock can be improved, nor can the present situation be maintained."

When discussing the construction of ranges in the next 3 years, the meeting requested that the fenced grassland area be expanded from the present 7 million mu to 9 million mu in 1985 and the artificial grassland area, from 2 million mu to 3 million mu in 1985. In addition, efforts will be made to solve the problem of drinking water for people and animals in the (Dong Chun) grassland area and to expand the usuable grassland area.

COMMENTARY STRESSES LIVESTOCK TURNOVER

HK240725 Xining Qinghai Provincial Service in Mandarin 1100 GMT 23 Nov 82

[Station commentary: "Speed Up Livestock Turnover, Raise Commodity Rate of Animal Husbandry"]

[Excerpts] In promoting commodity economy in our province's pastoral areas a problem merits our attention, in particular the attention of leaders at various levels. The problem is that some of our cadres and commune members begrudge selling their livestock and like to keep them as their own property. They are unwilling to sell the livestock which should be sold. Consequently, this livestock consumes a certain amount of forage for nothing. If natural disasters hit them, then great losses will ensue.

The modern pastoral industry must be developed for a high commodity rate. If the quantity of livestock increases but the commodity rate is not raised, then neither the state nor herdsmen will benefit. In discussing the promotion of commodity production in pastoral areas, we should grasp the key point of speeding up livestock turnover. Concentrating on this point, we will be able to work steadily and make solid progress in ironing out all contradictions in this field. In considering problems such as the building and management of grasslands and evolving new breeds, we must aim at speeding up livestock turnover. Of course, in our efforts to raise the commodity rate, we must look ahead and back. We must take account of immediate and long-term interests. Not only should we improve economic results at present, but also we should think of expanded production in future. The commodity rate of livestock in our province is lower than that in other provinces. This is mainly due to the fact that ranges are not well built and managed so that the rate of livestock turnover is low. To raise the commodity rate, leaders should first and foremost change their guiding thinking, attach importance to commodity production, pool wisdom and efforts of everyone to promote livestock turnover and acquire proficiency in building grasslands and in the scientific rearing of animals.

WINTER WHEAT MANAGEMENT CONFERENCE HELD

HK160931 Xian Shaanxi Provincial Service in Mandarin 1130 GMT 15 Nov 82

[Summary] The provincial CPC committee and government convened a winter wheat field management experience exchange conference in Qianxian County, which closed yesterday morning. Vice Governor Bai Jinian delivered a speech at the closing meeting and put forward three points:

"1. We should make the masses of people fully understand the harm of close planting and luxurious growth of seedlings on wheat land and further launch a campaign on winter wheat field management.

"2. Technically, the masses must be instructed in various categories and different measures in accordance with expert instructions and in line with local conditions.

"3. The method of on-the-spot displays should be widely applied so that the wheat field management system is popularized among all households and is converted into the conscious action of the peasants."

During the conference, wheat experts put forward their views on sparse seedlings and close seedlings after a drop in temperature:

"We should give scientific explanations to the peasants on sparse seedlings and on putting close seedlings under control. This is to ensure that wheat seedlings live through the winter, and that the sparse seedling problem can be solved easily, for an increasing number of peasants are ready to believe science. Therefore, frozen wheat field management of luxurious growth of seedlings in northern parts of the province may be temporarily postponed. The temperature in the Guangdong area is probably rising again and wheat plants seem to be growing before mid-December. So the field management of close planting and the luxurious growth of seedlings must not be relaxed because of a drop in temperature. We must seize the favorable opportunity provided before the land freezes and strive to do good job in green manuring."

BRIEFS

JOINT ENTERPRISES COMPANY--The Shaanxi Provincial Agricultural Reclamation and Agricultural-Industrial-Commercial Joint Enterprises Company started recently. This company runs 12 enterprises, which include agriculture, animal husbandry, industry, commerce and supply and marketing, and 6 units, which include scientific research, culture and education and public health. The aim of the company is to take part in the business activities organized by the China Agricultural Reclamation and Agricultural-Industrial-Commercial Joint Enterprises Company, to run agricultural-industrial-commercial comprehensive business, to establish economic links with the provincial agricultural reclamation units and to mediate between commerce and supply and marketing. [Xian Shaanxi Provincial Service in Mandarin 1130 GMT 15 Nov 82 HK]

BUMPER HARVEST--Shaanxi Province has reaped a bumper agricultural harvest this year. Total output of grain for the whole year may amount to 17.86 billion jin, 19 percent more than last year. Of it, total output of summer grain was 8.86 billion jin, the highest record since the founding of our country. Although the area sown with autumn grain is some 1 million mu less than last year and there was more rain at the final stage, it is estimated that total output of autumn grain will be about 9 million jin. Total output of cotton may exceed 2 million dan, 60 percent more than last year. Output of oil-bearing crops, mulberries, tea, flue-cured tobacco, sugar and draft cattle this year was more than last year. SHANDONG REAPS GOOD GRAIN, COTTON HARVESTS

OW100835 Beijing XINHUA in English 1148 GMT 9 Dec 82

[Text] Jinan, 9 Dec (XINHUA)--Shandong Province, which attracts nationwide attention for becoming China's number one cotton producer, this year reaped good harvests of both grain and cotton, according to the provincial agricultural department.

The 1982 cotton output was about 950,000 tons, more than one-fourth of China's total and 40 percent more than 1981, the department said.

This year, the area under grain was reduced by 8 percent or 530,000 hectares, which were largely given over to cotton. but grain output reached more than 23.5 million tons, still higher than last year.

Cotton production expanded rapidly in recent years. The 1979 output was only 166,500 tons. The 1980 output jumped to 537,000 tons, triple 1979's.

Other cash crops, forestry, animal husbandry, and fishery and other side-line occupations also made headway.

The province registered a 9 percent growth in agricultural output value which stood at 22,900 million yuan this year. Agricultural output value rose 7.3 percent annually between 1979 and 1981.

Per capita annual income of the province's 70 million peasants is expected to reach more than 150 yuan.

The province suffered a serious drought last spring. The provincial government allocated more than 58 million yuan for irrigation projects and facilities.

LETTER ON REALISTIC COMPUTATION OF INCOME

SK261256 Jinan DAZHONG RIBAO in Chinese 12 Nov 82 p 3

[Letter by Yu Yongbao of Wubei commune, Laixi County: "Realistic Computation of Per Capita Income"]

[Text] The annual autumn income distribution work has begun. The masses are eager to get their share of the good harvests and enjoy the fruits of the policy. Therefore, it is incumbent on cadres at all levels to work out a distribution plan in earnest, correctly handle the relationship between the state, collective and individual and compute per capita income in a practical and realistic manner.

In previous income distributions, some cadres, influenced by "leftist" ideas and blinded by the desire to overstate per capita income, more often than not exaggerated achievements and made false reports on output figures, giving rise to the phenomenon of false accounts and deceptive per capita distribution figures. Such a practice did great damage to the interests of the peasants, imperiled the collective economy and left many evil consequences.

As far as I know, the practice of concentrating on per capita income alone still prevailed to a fair extend as late as last year. To get a round number of per capita income figure such as 180 yuan, some production teams included the grains and vegetables produced on the commune members' private plots in calculating their per capita income. Rabbits purchased by commune members from the market, as well as chickens, ducks and geese raised by them, were evaluated in terms of money and, with their purchasing costs not deducted, counted as their per capita income. Consequently, what the commune members got were "dud checks." A production brigade made it by hook or by crook in achieving a per capita distribution of 200 yuan. However, immediately after the distribution the brigade found itself totally wanting in production funds and had to procure loans to finance spring farming. A few production teams went so far as to borrow money from banks for autumn distributions. As a result, their liabilities increased, the public accumulation dropped and the collective economy became a mere skeleton.

Why did the abovementioned phenomenon arise? First, a few vain [word indistinct] cadres wanted to gain a "reputation" by telling lies and enhance their social status by increasing "per capita income." Second, some leadership did not pay attention to investigation and research and relied solely on the reported figures to evaluate whether the job was well done and whether the achievements were big or small. This inspired people to resort to deception and unscrupulously overstate per capita income.

Onesided, blinded pursuit of per capita income is very harmful. Many of us have suffered from the bitter consequences of the "practice of boasting and exaggeration" prevailing in the late 1950s. During the "Cultural Revolution," Lin Biao and Jiang Qing inflicted wounds on the country, the party and the people by means of boasts, lies and deceptions. The memory is still deep. We must earnestly bear in mind this lesson of history.

Everyone of us communist party members and cadres should be an honest person, honest in word and in deed. We should always respect the truth, set the interests of the people and the party above everything else and report our situation as it is to the higher level. It is hoped that leadership at all levels will improve its style of work and conduct meticulous investigation and research. It is necessary to work out this year's autumn distribution plan by seeking truth from facts and honestly report every figure. This is also an important aspect of conscientiously improving the party's workstyle.

USING RURAL ENERGY RESOURCES URGED

SK211209 Jinan Shandong Provincial Service in Mandarin 2300 GMT 20 Nov 82

[Station commentary: "Accelerate the Exploitation and Utilization of Rural Energy Resources"]

[Text] Energy poses a big problem in the modernization of agriculture. In his report to the 12th CPC Congress Comrade Hu Yaobang regarded the energy problem as a strategic priority for economic development. Rational exploitation and utilization of rural energy resources is an important task facing us. At present waste of rural energy resources is colossal. Stalks are usually burned as fuel without being fully utilized. Because compost made of stalks was not returned to the farmland to regulate the chemical and physical functions of the soil and increase the soil's organic matter, land productivity dropped and production was adversely affected. Meanwhile, with the decrease in farmland and the increase in the demands for animal feed, it becomes increasingly difficult to solve the rural energy shortage by relying on [word indistinct] and stalks alone. Therefore, a solution to the rural energy problem is indeed an important undertaking that cannot be neglected.

To solve this problem we should, first of all, accelerate the exploitation of energy resources and make full use of biological energy. Being regenerative energy, biological energy requires little investment, yields quick results and has multiple uses. Take marsh gas. It can be used for cooking and illuminating and its waste residue can be used as fertilizer. Now the province has 600,000 marsh gas pits. If we accelerate the development of these pits and pay adequate attention to quality, by the end of the century we will have built 14 million marsh gas pits which will provide 50 percent of the energy supplies needed by rural areas.

Second, we should develop fuel forests. Fuel forests, after being planted, can be used for many years. Besides this, rural areas should also actively study and develop new energy resources. Our province abounds with hydropower potentials, solar energy, wind power and tidal power. The hydropower resources alone, if converted into electricity, amount to 440,000 kw. Many localities in the countryside have begun to utilize small-scale hydropower resources and solar energy and have opened up broad horizons for studying and developing new energy resources.

In solving the rural energy problem, efforts should be made to combine exploitation with conservation and pay attention to improving economic efficiency. We hope that industrial departments will provide rural areas more advanced electricity- and coal-saving equipment and machinery for utilizing rural energy sources. Commune and brigade-run enterprises should develop more products which require low energy consumption and whose production does not require them to scramble for raw materials with large enterprises. Provided we combine various methods, increase energy resources and reduce consumption, we stand a very good chance of success in solving the rural energy problem.

SHANDONG RADIO ON STOPPING BUILDING HOUSES ON FARMLAND

SK200947 Jinan Shandong Provincial Service in Mandarin 2300 GMT 19 Nov 82

[Station commentary: "Resolutely Stop the Trend of Building Houses on Cultivated Land"]

[Excerpts] Recently the secretariat of the CPC Central Committee and the State Council called on all localities to bring the situation of building houses on cultivated land under strict control and resolutely stop the trend that cadres take the lead in building houses on cultivated land.

In order to implement the guidelines of the directive, the provincial construction commission held a special meeting to work out specific measures urging all localities to stop rural housing construction from overrunning farmland in the next few years. A conscientious investigation should be conducted on rural housing construction. Those units and individuals that arbitrarily build houses on cultivated land should be dealt with severely.

At present we should attach prime importance to stopping the unhealthy trend of building houses on rural cultivated land. All relevant departments throughout the province and the broad masses of the people and cadres in rural areas should be mobilized immediately to resolutely put an end to activities that overrun farmland for housing construction, that violate the relevant regulations on land for housing construction formulated by the state and the provincial, prefectural and county governments at all levels. In line with the demands of the party Central Committee, those units and individuals that violate the regulations should be severely investigated and handled.

Following thoroughgoing and painstaking ideological and organizational work, we should widely publicize the relevant policies of the state and the stipulations of the law among cadres and the masses and formulate realistic plans for rural housing construction with a view to enthusiastically helping peasants solve problems in housing construction.

So long as leaders at all levels attach great importance to conscientiously economizing every inch of land, and party-member cadres set examples for cadres and the masses in this goal, the unhealthy trend of building houses on farmland will certainly be stopped.

BAI RUBING PARTICIPATES IN AFFORESTATION LABOR

SK140414 Jinan Shandong Provincial Service in Mandarin 2300 GMT 14 Nov 82

[Excerpts] On 13 November, over 500,000 civilians and armymen in the provincial capital Jinan participated in the communist voluntary labor day activities to carry out winter afforestation and environmental sanitation work. They heightened their spirit, and worked together with one heart to plant 1,500 trees, sweep some 3,000 streets and lanes and remove over 10,000 tons of trash in a day, thus cleaning up some 3,000 unsanitary places and enabling the city to have a great change in appearance.

Responsible comrades of the provincial CPC committee, the provincial people's congress, the provincial government and the provincial CPPCC committee, including Bai Rubing, Su Yiran, Zhao Lin, Gao Qiyun, Li Zichao, Wang Jinshan, Xu Leijiang, Zhao Feng, Lin Ping, Chen Lei, Yang Jieren, Wang Baomin, Song Yimin, Liu Peng, Liu Zhongqian, Ding Fangming, Wang Zhe and Zhang Weicen; responsible comrades of the Jinan PLA units including Chen Renhong, (Zhang Feng), (Li Suiying), (Pan Qiqi), (Xu Zhongyu) and (Xu Chunyang), responsible comrades of Jinan Municipality including Wei Jianyi, (Zhang Jun), (Li Ke), (Chen Baoxi) and (Xu Zhenjie), led some 1,500 office cadres and PLA commanders and fighters in afforestation labor at north (Dongyi) road in the eastern suburban area of Jinan Municipality on the morning of 13 November.

The broad masses of cadres from various municipal organizations, PLA units stationed locally, plants, schools and neighborhoods also participated in environmental sanitation work in the designated areas where the sanitation responsibilities were fixed by contract. Some 80 department and bureau directors of provincial-level organs led office cadres in cleanups of their office surroundings. Some 10,000 commanders and fighters of the Jinan PLA units also took to the streets to remove trash and to participate in serve-the-people activities along with the masses.

SHANDONG

BRIEFS

DIVERSION WORKS--Shandong Province has successfully completed the project to divert Huanghe water to Tianjin. The daily amount of water delivered to Tianjin reaches over 8 million cubic meters. [SK170225 Jinan Shandong Provincial Service in Mandarin 2300 GMT 15 Nov 82 SK]

COTTON OUTPUT--Jinan, 26 Oct (XINHUA)--Shandong reaps good cotton harvests this year with cotton output increasing by a big margin over 1981 production. By 25 October, the province procured 10,390,000 dan of new cotton from the producers and overfulfilled the procurement plan by 1,230,000 dan. This year's cotton procurement was some 5 million dan larger than procurement in the same period in 1981. [OW150209 Beijing XINHUA Domestic Service in Chinese 1131 GMT 26 Oct 82 OW]

GINNED COTTON PROCUREMENT--As of 7 November, Shandong Province had procured 13,218,000 dan of ginned cotton, a 168,000 dan increase over 1981. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 8 Nov 82 SK]

COTTON HARVEST--It is estimated that this year Shandong Province will harvest 18 million dan of cotton on 20 million mu of lands, an increase of over 5 million dan over 1981. As of 10 October, the province had procured 9.22 million dan of cotton, a 95.6 percent increase over that of the corresponding 1982 period [as printed]. [Jinan DAZHONG RIBAO in Chinese 22 Oct 82 p 1 SK]

AGRICULTURAL PRODUCTION--Since the third plenum, Shandong Province's Dezhou Prefecture has scored achievements in agricultural production. Comparing 1978 with 1981, the agricultural income of the prefecture showed a 1.3-fold increase and reached 1,326 million yuan, grain output increased from 3,025 million to 3,423 million jin, cotton output increased from 398,000 to 3,390,000 dan and oil crops rose from 22 million to 43 million jin. [SK101127 Jinan DAZHONG RIBAO in Chinese 19 Oct 82 p 1 SK]

GRAIN, PEANUT OUTPUTS--Taian Prefecture, Shandong Province, has successfully fulfilled its 1982 grain and peanut procurement plans. By 10 November, the prefecture had procured over 470 million jin of grain and over 29 million jin of shelled peanuts and had them stored well. The prefecture prefulfilled its grain procurement plan by over 20 days and peanut plan, by over 1 month. [SK160142 Jinan Shandong Provincial Service in Mandarin 2300 GMT 14 Nov 82 SK]

COTTON, GRAIN HARVESTS--In 1982, Shandong Province's Liaocheng Prefecture reaped bumper cotton harvests. It is expected that the prefecture will harvest 4.5 million dan of cotton this year, an increase of about 1 million dan over 1981. As of 21 November, the prefecture had sold 3.66 million dan of ginned cotton. This year, the prefecture harvested 2,580 million jin of grain, showing an increase of 110 million jin over that of 1981. This year, the prefecture earned 560 million yuan from diversified economy, a 100-percent increase over 1978. The prefecture's annual agricultural output value in 1982 reached 1,820 million yuan, an increase of more than 200 percent over 1978. [SK270711 Jinan Shandong Provincial Service in Mandarin 2300 GMT 25 Nov 82 SK]

SUBMARINE CABLE--The first 35,000-volt submarine cable of Shandong Province was completed and went into operation on 31 October. The submarine cable is between Penglai and Changdao counties, the latter being an island county that is the last county in the province to be merged into the Shandong power grid. The four-wire cable is 11 km long with a total weight of 660 tons. It was especially designed by the Shanghai cable plant for transmitting electricity to offshore islands of our country. [Jinan DAZHONG RIBAO in Chinese 12 Nov 82 p 1 SK]

GRAIN HARVEST--This year, Shandong Province harvested 47 billion jin of grain, a 1 billion jin increase over 1981. [SK050340 Jinan Shandong Provincial Service in Mandarin 2300 GMT 3 Dec 82 SK]

LINQING COUNTY COTTON HARVEST--Linqing County, Shandong Province, has reaped a bumper harvest on its 500,000 mu of cotton fields with per-mu yield reaching 130 jin and total output 650,000 dan, a record. [Jinan Shandong Provincial Service in Mandarin 2300 GMT 5 Dec 82 SK]

SHANDONG AFFORESTATION PROGRESS--Jinan, 7 Nov (XINHUA)--The spring-summer tree-planting drive this year has added to Shandong Province more than 48,000 hectares of afforested hilly land, 28,000 hectares of nurseries, 210 million trees along roadsides and around houses and 165,000 hectares of windbreaks bordering fields, according to a recent provincial forestry conference. The province now has a total of 1.4 million hectares of afforested land, 2.4 million hectares of farmland shelter belts, and 480,000 hectares interplanted with date and tung-oil trees, in addition to 240,000 hectares of fruit trees. The afforestation campaign over the past years has increased the forest cover in the province to 9.2 percent as against 1.9 percent some thirty years ago. The three have not only diminished soil erosion and provided fruits and fuel, but also increased provincial timber reserves to 26 million cubic meters. URGENT MEETING HELD ON FOREST DESTRUCTION

HK130526 Taiyuan Shanxi Provincial Service in Mandarin 2300 GMT 12 Nov 82

[Summary] The Shanxi Provincial People's Government recently held an urgent conference in Taiyuan on curbing indiscriminate lumbering. The meeting pointed out: The evil wind of indiscriminate lumbering has been curbed in some places in the province in the past 2 years. However, in many places it has never been arrested. This particularly applies to Jishan, Fangshan, Shenchi, Fanshi and Hongtong counties, where forest destruction has tended to spread and develop.

The problems aired at this meeting showed: "Large tracts of state forest have been seized and cut down in these places. In some places there is not one tree left. Apart from brazenly seizing and looting the forests, some people even savagely beat up forestry protection and public security personnel, heaving in an extremely arrogant fashion."

The meeting pointed out: "The leading cadres in these counties have long lacked sufficient understanding of the gravity of indiscriminate lumbering there and have paid no attention to it. Some have even protected and connived at those who engage in it. In addition the law enforcement departments there have failed to enforce the law. In particular, they have failed to effectively handle certain major and important cases. For instance the instance of tree-fellers in Jishan County beating up Xiangning County forestry protection and public security personnel, which occurred in April, was not handled for a long time. In counties where some cases have been dealt with, only the ordinary masses and not the grassroots cadres have been punished. As a result, many grassroots cadres have become still more bold in directing or personally leading people up the mountains to engage in indiscriminate lumbering. In addition, certain forestry management departments have failed to carry out regulations and engaged in embezzlement. For instance, the Fangshan County Forestry Bureau has long engaged in illegal activities in lumbering, sales, transport and so on. This has intensified forest destruction."

Vice Governor Wu Guangtang stressed at the meeting: "We must seriously implement the urgent instructions of the Central Committee and State Council and immediately arrest the destruction of forests. Specifically, the whole party must get mobilized to take comprehensive measures to deal with the problem. In particular, the county party and government leaders must take the lead in implementing the spirit of the urgent central instructions and mobilize the forces of all sectors to publicize them deeply and extensively among the masses." It is essential to cultivate an excellent social mood of planting, cherishing and protecting trees. Appropriate punishment must be meted out to units and individuals engaged in indiscriminate lumbering. The management departments must improve and systematize their work. Party and government leaders must take concrete and effective steps to immediately curb the evil trend of forest destruction.

WATER, SOIL CONSERVATION URGED

SK071115 Taiyuan SHANXI RIBAO in Chinese 14 Nov 82 p 1

[Commentator's article: "The Lifeblood of Mountainous Area Construction"]

[Excerpts] In our province, 60 percent of the land suffers from soil erosion. In eroded areas, only by making consistent efforts in water and soil conservation to protect soil, fertility and water, can agriculture, forestry, animal husbandry and sideline production be greatly developed and culture, education, public health and transportation be promoted. Water and soil conservation is the lifeblood of economic development in mountainous areas and is the most important capital construction in these areas.

The purpose of checking soil erosion is to properly utilize water and soil resources and make land yield economic benefits. In view of our current actual situation, we should emphasize two tasks in order to achieve a good ecological cycle in our province's vast mountainous areas within a short period of time. First, we should deeply turn up the soil and improve land through farmland improvement projects, engage in scientific farming and turn our farmland into high- and stable-yield farmland so as to guarantee grain production. Second, we should sign various specialized contracts for improving rivulet basins and, in line with specific local conditions, develop diversified production, such as forestry, fruit, mulberry, tussah cocoon and medicinal herb production, plaiting industry and breeding so as to promote water and soil conservation work and enable mountainous areas to become prosperous at an early date.

Water and soil conservation is a great task for improving mountains and rivers, stopping poverty, achieving prosperity and benefiting the coming generations. All our party committees and governments should regard this task as an important component of mountainous area construction, further emancipate their minds, do their work boldly, fully arouse the enthusiasm of the masses of peasants, organize and coordinate financial, material and manpower resources of all departments and create a new situation in water and soil conservation work.

SHANXI

BRIEFS

YANBEI PREFECTURE FARM OUTPUT--Yanbei Prefecture, Shanxi Province, had an all-round good harvest of its 10 million mu of crops. Total grain output topped 2 billion jin, up 32.6 percent over the good harvest year of 1981. Output in four of the prefecture's 12 counties--Ying, Suo, Huiyuan and Yanggao--surpassed 200 million jin. Output of the prefecture's 1.27 million mu of oil-bearing crops was 116.54 million jin, an increase of 97 percent over the best amount on record. Some 164,000 tons of sugarbeets were reaped on 130,000 mu of land, up 72 percent over 1981. The prefecture's income from collective agriculture is expected to reach 490 million yuan, up 53 percent over 1981; per capita distribution for the collectives is expected to be 143 yuan, an increase of 65 yuan over 1981. [SK210114 Taiyuan SHANXI RIBAO in Chinese 28 Oct 82 p 1 SK]

HIGHWAY CONSTRUCTION--Over the past 3 years Shanxi Province, in addition to arterials, has had 1,890 km of highways built by counties and communes, of which 579 km are up to the standards of fourth-grade highways. Some 280 km of asphalt roads, 75 large and medium-sized bridges with a total length of 3,906 meters and 14 tunnels with a total length of 1,637 meters have been constructed in that period. The province's 1982 plan for rebuilding 1,875 km of highways has by and large been completed. The plan for constructing 21 large and medium-sized bridges with a total length of 1,990 meters has been virtually completed. [Taiyuan SHANXI RIBAO in Chinese 29 Oct 82 p 2 SK]

JINNANDONG PREFECTURE HIGHWAY CONSTRUCTION--Jinnandong Prefecture, in Shanxi Province, has actively mobilized people in the prefecture to build highways to improve traffic in mountainous areas. In the past year or so, construction on 118 highways with a total length of 1,248 km has begun, of which 85, with a total length of 1,004 km, have been completed and open to traffic. [Taiyuan SHANXI RIBAO in Chinese 29 Oct 82 p 2 SK]

SHANXI COTTON PROCUREMENT--By 25 October Shanxi Province had procured 547,000 dan of ginned cotton, fulfilling 42 percent of the plan. [Taiyuan SHANXI RIBAO in Chinese 30 Oct 82 p 1 SK]

PINGLU COUNTY GRAIN OUTPUT--Pinglu County, Shanxi Province, has reaped a bumper grain harvest this year. According to statistics, the 119.3 million jin of grain and 10.06 million jin of oil-bearing seeds. Thanks to the bumper harvest resulting from the enactment of production responsibility systems, the county has scored a per capita income of 194 yuan this year, compared with only 20.1 yuan in 1978. Meanwhile, it is expected the county will hand over 15 million jin of grain and 1.5 million jin of oil-bearing seeds to the state this year. [Taiyuan SHANXI RIBAO in Chinese 31 Oct 82 p 1 SK]

BUMPER COTTON HARVEST--Shanxi Province has reaped a bumper cotton harvest this year. By 20 November, the province had procured some 131 million jin of new ginned cotton, which accounted for some 100 percent of the state annual quota and was some 200 percent more than in the corresponding period last year. [Taiyuan Shanxi Provincial Service in Mandarin 2300 GMT 24 Nov 82 HK]

YUNCHENG PREFECTURE COTTON HARVEST--This year Yuncheng Prefecture, Shanxi Province, has reaped a good harvest on 1.97 million mu of cotton fields. Total yield of ginned cotton will reach 1.07 million dan and that of marketable cotton will reach 1 million dan. [SK271245 Taiyuan SHANXI RIBAO in Chinese 10 Nov 82 p 1 SK]

YANBEI PREFECTURE OIL-BEARING SEEDS--Yanbei Prefecture, Shanxi Province, has reaped a bumper harvest on 1.13 million mu of oil-bearing seeds fields. Total output has reached 114.49 million jin, an increase of 93.5 percent over 1978. [Taiyuan SHANXI RIBAO in Chinese [no date and page given]

NOTICE ON 'INDISCRIMINATE' TREE-FELLING DISCUSSED

HK300159 Chengdu Sichuan Provincial Service in Mandarin 2300 GMT 29 Nov 82

[Summary] The Sichuan Provincial CCP Committee and government issued a circular on 16 November on implementing the urgent central instructions on curbing indiscriminate tree-felling. The circular pointed out: "Indiscriminate tree-felling has never ceased in some places in the province. In a few places, this practice is even growing more and more rampant. The main reason for this is that the party and government leading organs concerned lack sufficient understanding of the importance of illegal destruction of forests and fail to deal effective blows at it. Some even ignore the matter completely and let things go their own way."

The circular demanded that party committees and government throughout the province seriously study and resolutely implement the urgent central instructions, put a stop to the evil practice of indiscriminate tree-felling and create a new situation in forestry. The circular made the following points:

1. Party committees and government must seriously check on whether indiscriminate tree-felling has been halted. All forest farms, communes and brigades must carry out this check. Cases discovered must be severely dealt with immediately, in the appropriate way.

2. The key to curbing indiscriminate tree-felling lies in the cadres. The cadres, CPC and CYL members must set an example for the masses in observing the law and caring for the forests, and also wage resolute struggle against destruction of forests. Forest destruction cases involving cadres, especially leading cadres, must be severely dealt with.

3. Stabilize the mountain and forest rights and implement the forestry responsibility systems. This is a fundamental measures for curbing indiscriminate tree-felling. This work must be completed and forestry rights certificates issued by yearend.

4. Forestry management work must be strengthened. The procedures for cutting down state-owned and collective trees must be strictly followed. No trees may be cut without permission. Timber free markets may not be opened in forest area counties and communes and in areas bordering forests, and those that have been opened must be closed.

5. The urgent central instructions must be publicized with great fanfare, to ensure that everyone knows them.

SICHUAN NPC DEPUTY ON RESPONSIBILITY SYSTEM

OW060843 Beijing XINHUA in English 0739 GMT 6 Dec 82

[Text] Beijing, 6 Dec (XINHUA)--Li Linzhi, a deputy from Sichuan Province to the National People's Congress, said here today that the adoption of a responsibility system has been key to the rapid development of China's rural economy in recent years.

Now a vice chairman of the Provincial People's Congress Standing Committee, Li Linzhi worked for 15 years as vice governor of Sichuan in charge of agricultural work.

He told XINHUA that under the responsibility system, collectively-owned land is apportioned among working groups or peasant households, who will work the land in line with the requirements of the state plan, deliver a fixed amount of their products to the state and the collective as is laid down in the contracts they have signed with their collective, and keep the rest of their output. Land remains the property of the collective.

Li Linzhi said this system has given the initiative to the peasants and encouraged them to display their ability to the fullest.

Since the system was introduced on a trial basis in 1978, first in some places, he said, Sichuan's grain output has increased every year and is expected to reach 37 million tons this year, or six percent more than 1981.

Before coming here to attend the National People's Congress, Li Linzhi visited four counties in Sichuan. He found in every household a sizable store of surplus grain. "Cats have become a most welcome animal among the peasants, because the grain storage is drawing an increasing number of mice," he said.

A sample survey of 125 rural production teams in Sichuan shows that the average income for each person there in 1981 was 221 yuan, nearly double that of 1978 or 2.5 times the annual average for the 20 years from 1957 to 1976.

In 1981, Li Linzhi said, each peasant of these production teams consumed an average of 254.5 kg of grain, 15.75 kg of meat, and 2.55 kg of wine.

Meanwhile, total savings deposits throughout Sichuan's rural areas last year were 4.6 times the 1978 figure.

More than ever before, he said, the peasants are eager to improve their farming technique through the study of science.

Sichuan is one of the first provinces in China to introduce the responsibility system in farm production. Since they are now free to arrange their time and work, many peasant households have found time to undertake more side occupations, such as raising poultry or weaving straw mats. Gradually, some of these households began doing such jobs full time. Their skill and efficiency has given them higher income. In Wenjiang Prefecture, some 100 households earned an average income of about 10,000 yuan last year.

Though such households now account only for 8 percent of the total number of peasant households in the prefecture, Li Linzhi said, they represent an embryo of specialized commodity production, which will further invigorate the rural economy.

As production develops, he continued, specialized households have begun joining hands on a voluntary basis to expand production in such areas as bee keeping and flower planting.

"This development is inevitable, because it conforms to the objective laws of economics," Li Linzhi said.

SICHUAN

BRIEFS

WATER, SOIL CONSERVATION--A Sichuan provincial conference on water and soil conservation was held in Pujiang County from 4 to 9 December. The meeting studied and conveyed the spirit of the fourth national conference on this topic, introduced the experiences of Pujiang and Suining Counties, and discussed and amended the provincial regulations on water and soil conservation. The meeting held: "Sichuan has scored a certain degree of success in water and soil conservation work. However, due to the influence of leftist ideology together with errors in work, forests and vegetation have been seriously damaged, resulting in extremely serious soil erosion in many places. Major flood disasters have occurred in the past 2 years. Failure to grasp water and soil conservation well was one of the reasons for this. Hence, water and soil conservation is indeed a lifeline in construction in mountain and hilly areas, a fundamental measure for harnessing the rivers, and a major aspect of tidying up the land." The meeting demanded that the cadres and masses seriously study and implement the provisions in the new constitution on protecting the ecological environment and natural resources, and strictly adhere to the regulations on water and soil conservation promulgated by the State Council. Departments concerned must closely cooperate to formulate local water and soil conservation plans and also be responsible for carrying them out. The province should strive to change its ecological environment from a vicious to a benign cycle within 10 years. [HK100321 Chengdu Sichuan Provincial Service in Mandarin 2300 GMT 9 Dec 82]

AGRICULTURAL PRODUCTION--The provincial statistics bureau estimates that Sichuan has reaped another bumper harvest this year, for the sixth time since the "gang of four" were smashed. Despite a reduction in the sown area of 2 million mu, total grain output is expected to show a new record by reaching 74 billion jin, an increase of 5.3 billion jin over last year. Total rice output is estimated at 35.4 billion jin, an increase of 2.6 billion jin over last year. Wheat production was 12.7 billion jin, an increase of 2.4 billion jin over last year. The biggest production increases were recorded in Mianyang, Nanchong, Neijiang and Wenjiang prefectures, which were hit by severe natural disasters last year. The province scored relatively great increases in industrial crop production, except for cotton, jute and bluish dogbane, the planned sowing areas of which were cut. According to statistics, silk cocoon production reached 1.93 million dan, 7.4 percent higher than last year. Tea output may reach 68,000 dan, a rise of 4.3 percent. The number of pigs at yearend is expected to be about 50.5 million, an increase of 0.5 percent over the same time last year. Total agricultural output value is estimated to show a rise of 1.8 billion yuan--8.5 percent--over last year. [HK020411 Chengdu Sichuan Provincial Service in Mandarin 2315 GMT 1 Dec 82]

JOINT VENTURES DEVELOP--Agricultural-commercial joint ventures in Sichuan Province have developed vigorously. By the end of August, some 130 county supply and marketing cooperatives throughout the province had begun developing agricultural-commercial joint ventures. About 140,000 production teams and specialized groups, some 550,000 specialized households and commune members' sideline households and some 630 commune and brigade enterprises and other production and management units have taken part in agricultural-commercial joint ventures, which now produce fruit, tea, draft cattle, lacquer, bamboo, poultry, fish, mushrooms, pepper and vegetables and process cotton, tinned food, brews and building materials. Through this transformation, production, supply and sale of agricultural and sideline products can be even better coordinated. BRIEFS

WATER PROVISIONS--On 1 November the (Weishan) sluice gate in Liaocheng Prefecture of Shandong Province was lifted 15 days ahead of schedule to deliver Huang He water to Tianjin. According to plans for this autumn and winter, Huang He water is to be delivered to Tianjin from the (Weishan) sluice gate in Liaocheng Prefecture and the (Panzhuang) sluice gate in Dezhou Prefecture of Shandong Province beginning 15 November. [Tianjin City Service in Mandarin 0030 GMT 3 Nov 82 SK]

FORAGE INDUSTRY--Tianjin has made rapid progress in the forage industry. Over the past 3 years, the output and sales volume of mixed feed have increased at an average rate of 71.6 percent annually. Three years ago, the municipal annual production capacity of forage was 32 million jin. By the end of September 1982, Tianjin had 11 medium-sized mixed feed plants. Their annual production capacity was from 3,000 to 5,000 tons. By the end of this year, Tianjin's total production capacity of mixed feed will reach 130 million jin. Three years hence, Tianjin will have 25 medium-sized mixed feed plants and the total annual production capacity will reach 500 million jin. [SK040252 Tianjin City Service in Mandarin 1430 GMT 29 Oct 82 SK]

GRAIN OUTPUT--Combatting 3 consecutive years of droughts, Tianjin city reaped good harvests of grains, cotton and oil-bearing crops. The city's total grain output is approximately 2.4 billion jin, registering an increase of nearly 20 percent over the 1981 figure. The total cotton output is expected to be 9.14 million jin, doubling the 1981 figure. The total output of oil-bearing crops is 84 million jin, showing an increase in per-unit output. The city's total agricultural output is estimated to be approximately 2 billion yuan, a 7-percent increase over 1981. [Tianjin City Service in Mandarin 0030 GMT 3 Dec 82 SK]

RURAL ECONOMY--The rural economy is growing more and more prosperous in Ninghe County, Tianjin Municipality. Ninghe County has reaped bumper harvests in grain, cotton and oil-bearing seeds this year despite serious drought. Grain output totals 250 million jin, an increase of 24 percent over 1981. Output of ginned cotton totals 2.45 million jin and per-unit yield averages 70 jin, a record high. Although the acreage sown to oil-bearing seeds decreased this year, total output still holds the record. It is estimated that total agricultural output value will increase by 16 percent over 1981. This year each peasant owns 937 jin of grain, up 91 jin over 1981. Per capita income will reach 300 yuan, up 70 yuan over 1981. A half of the 60,000 peasant households will have over 1,000 yuan of income. Savings deposits of peasants total 11 million yuan, up 28 percent over 1981. Over the past few years, peasants throughout the county have built 104,000 new houses, accounting for one-third of the total. [Tianjin City Service in Mandarin 0030 GMT 25 Nov 82 SK]

CIRCULAR ON CURBING TREE-FELLING ISSUED

HK190337 Urumqi Xinjiang Regional Service in Mandarin 1300 GMT 18 Nov 82

[Summary] The Xinjiang Regional CPC Committee and government issued a circular on 15 November on implementing the urgent instructions of the Central Committee and State Council on curbing indiscriminate tree-felling.

The circular said: "Since implementing the State Council's urgent circular and the decision of the Central Committee and State Council on a number of questions in protecting the forests and developing forestry, instances of destroying forests for reclaiming land for agriculture or grazing and large-scale indiscriminate tree-felling have been basically curbed. However, the problem of indiscriminate tree-felling remains very serious in some places. There are still problems of failure to observe the forestry protection laws or strictly enforce them, and illegalities and anomalies in timber management. The main reason is that the party and government leaders in some places lack sufficient understanding of the importance of forestry. They hold that as forest rights are not owned by the local authorities, it is no business of those authorities if the forests suffer destruction. Others say, the forest is growing here, and it is natural to cut it down and use it. Hence, they do nothing about indiscriminate tree-felling and illegal elements and speculate in timber. As a result, incidents of forest destruction are tending to spread and develop in some major forestry areas. Unless we take urgent action to deal with these problems, trees that have taken a century to grow will be destroyed in a moment and irreparable damage will be done." The circular, therefore, made the following points:

1. Party committees and government at all levels must get a thoroughly good grasp of implementing the urgent instructions of the Central Committee and State Council. This particularly applies to county CPC committees and governments. Forestry protection work must be strengthened. No matter who owns the forest rights, the local party and government, especially the county CPC committees and governments, have the responsibility to protect and look after the forests. If they fail to do so, the upper-level party committees and governments must investigate the responsibilities of the county leaders.

2. Party discipline inspection departments, the public security departments, procuratorates and courts, and the industry and commerce administrative departments must cooperate with forestry departments in investigating cases of destruction of forests and speculation in timber. Speedy and severe punishment must be dealt out.

3. Do a proper job of defining forest rights, private forest tracts, and forestry responsibility systems. This work should be completed this winter and next spring.

4. Strengthen unified timber management and transport work.

5. Forestry departments must work out plans for closing the mountains to facilitate afforestation and protect the forests.

The circular said: The regional CPC committee and government have decided to dispatch work teams to inspect the implementation of the urgent central instructions in key parts of Xinjiang. The local party committees and governments must cooperate with these teams and help them in their work.

LIVESTOCK PRODUCTION INCREASE NOTED

OW130946 Beijing XINHUA in English 0801 GMT 13 Nov 82

[Text] Urumqi, 13 Nov (XINHUA)--Xinjiang, one of China's five major pastoral areas, reports a record production of animal meat and other animal products this year.

According to the regional government, as of October 31 this year the region purchased 32,000 tons of meat, 15.8 percent more than the same period last year; 20,000 tons of wool for textile industry, 15 percent increase. In the same time the region exported 150,000 hides, 79 percent increase; 198 tons of cashmere, 32 percent increase; and 19 tons of camel hair, 19 percent increase.

Xinjiang had at the end of the 1982 stockbreeding year (July 1, 1981-June 30, 1982) 34.5 million head of livestock--a record and 1.54 million head or 4.68 percent more than last stockbreeding year. As of June 30, the region had 9.5 million young horses, cattle, camels and sheep, a 3.01-percent increase in the survival rate above 1981.

The regional government said livestock production in Xinjiang has gone up averagely by 4.5 percent each year since 1978 as a result of the new policies that benefit herders, and scientific methods of raising livestock.

Herders in Altay Prefecture have improved the variety of sheep and shortened the period of rearing. As of October 20, the prefecture had sold to the state 5,000 tons of meat, fulfilling the annual quota ahead of schedule.

Encouraged by the new policies, herders in the region have raised more domestic animals for personal needs. The region has 9.24 million head of privately owned livestock this year, an increase of 90 percent above 1978.

To raise more livestock, herders have increased the percentage of dams in the total livestock from 43.2 in 1978 to 45.7 last year. There were 12.93 million dams in the region last year, 20.8 percent more than in 1978.

Xinjiang has 80 million hectares of grassland, of which 50 million hectares or one-fourth of the nation's total can be used to feed domestic animals. Livestock raising in Xinjiang ranks second in the country, next to Inner Mongolia Autonomous Region.

XINJIANG'S AGRICULTURE, INDUSTRY MAKE ADVANCES

OW151255 Beijing XINHUA in English 1607 GMT 12 Nov 82

[Text] Urumqi, 12 Nov (XINHUA)--China's western-most Xinjiang Uygur Autonomous Region expects a bigger grain crop this year than last, despite inclement weather and natural disasters while cotton and sugarbeet production grew 30 percent and 35 percent.

The region also reports a record number of domestic animals, 29 million, on its vast pasture lands.

Wang Enmao, first secretary of the Regional Party Committee of the Chinese Communist Party, announced the figures Thursday at a conference commending organisations and individuals for contributions to unity among the region's nationalities.

Other achievements he cited for 1982's first nine months include an industrial output value of 3.19 billion yuan, an 8 percent increase from the same period last year, a 2 percent increase in capital construction and good returns in regional financial revenue.

Wang Enmao said the region, with the biggest single administrative area in China, has a bright future because of the work of the past 32 years. He said the region has modern factories and enterprises, producing iron and steel, machinery, coal, electricity, chemical products, cement, nonferrous metal, textiles, paper and other manufactured goods, Xinjiang's industrial have been marketed both nationwide and abroad. [sentence as received]

Wang said the region's 1981 industrial output value was 41.25 times the 1949 figure, while that of agriculture and animal husbandry was 5.33 times, with grain output 4.6 times higher and the number of domestic animals 2.7 times.

Along with development of production and transportation, he said, the region has 903 hospitals, 18.8 times the 1949 figure, and 12 colleges and institutes enrolling 7,900 students.

Wang said Xinjiang is appropriate for industry, agriculture and animal husbandry because of its size, one-sixth of China, and its resources. He called on the region's residents to turn it into a major supplier of cotton, sugarbeet, melon, fruit and domestic animals.

Rich coal anrljtroleum deposits he said, could make Xinjiang (?one) of China's great energy bases by the end of this century.

BRIEFS

NEWLY PROSPERING COMMUNE--According to reports by XIZANG RIBAO, Yin Fatang, first secretary of the Xizang Regional CPC Committee, while conducting investigations in Biru County, paid a special visit to the cadres and commune members of the (Mengqing) commune, which shook off poverty in 2 years and changed rapidly from poverty to prosperity. He encouraged them to try their best to become even more prosperous in the spirit of the 12th Party Congress. The (Mengqing) commune used to be the poorest commune in Biru County. By 1980, the commune members owed debts totaling some 19,700 yuan. In order to change this situation, the Nagqu Prefectural CPC Committee, the Biru County CPC Committee and the district CPC committee sent one work group after another to improve work there, but no marked results were obtained. In October 1980, the (Mengqing) commune implemented the production responsibility system of assigning land to each household in exchange for specific levies. This inspired the commune members with the hope of becoming well-off. Their enthusiasm for labor as masters of the commune became higher than ever before. Last year, with the efforts of all the commune members, the average output of the 1,312 mu of contracted land for grain crops in the commune was 159 jin, 13 percent higher than the average output in normal years since the commune was set up. The commune's income from sideline production totaled over 39,000 yuan, some 70 percent more than in 1980. The total income of the commune was 61 percent more than in 1980. Per capita income was 167.89 yuan, which exceeded the average level of the whole county. [Excerpts] [HK100313 Lhasa Xizang Regional Service in Mandarin 1130 GMT 9 Nov 82]

MEETING CALLS FOR CURBING TREE-FELLING

HK061230 Kunming Yunnan Provincial Service in Mandarin 1100 GMT 5 Dec 82

[Summary] Yesterday evening the Yunnan Provincial CPC Committee and the provincial people's government held a telephone conference on seriously implementing the urgent instruction of the CPC Central Committee and the State Council on curbing indiscriminate tree-felling. The conference put forward measures to curb indiscriminate tree-felling and stressed eliminating the unhealthy trend of indiscriminate tree-felling.

(Liu Shusheng), deputy secretary of the provincial CPC committee, presided over the conference. Zhang Yun, provincial CPC committee Standing Committee member and vice governor, spoke at the conference.

The conference pointed out: "Since the CPC Central Committee and the State Council issued the instruction on curbing indiscriminate tree-felling, the provincial CPC committee and the provincial people's government have organized seven work groups, which have gone to 11 prefectures, autonomous prefectures, municipalities and counties, to conduct supervision and inspections and to help them implement the urgent instruction. In coordination with them, political and legal departments at the provincial level have stepped up investigation and dealing with cases of damaging trees. All prefectures, autonomous prefectures, municipalities and counties have also implemented the instruction, taken various forms to conduct publicity and education in grassroots units, organized forces to deal with cases of damaging trees and taken some necessary measures to curb indiscriminate tree-felling."

In prefectures, autonomous prefectures and municipalities, including Kunming, Qujing and Honghe, and in counties, including Fumin, Lianghe and Fuyuan, leaders have attached importance to the work of curbing indiscriminate tree-felling, worked quickly and taken vigorous measures. Fumin County has basically eliminated the unhealthy trend of indiscriminate tree-felling. "However, judging from the situation of the whole province, the serious situation of indiscriminate tree-felling and of damaging forests has not been completely eliminated, old cases of damaging forests have not been thoroughly investigated and dealt with and new cases of damaging forests have occurred. Free timber markets in many places have not yet been closed down. Lumbering which is not being done in a planned way or is done beyond quotas still continues. Some places have not meted out severe punishments or have not struck vigorous enough blows in cases of apparent sabotage of forests in some places."

The conference stressed that in implementing the urgent instruction, a pressing matter at the moment is to immediately and resolutely curb the unhealthy trend of indiscriminate tree-felling. "In counties where this unhealthy trend cannot be curbed, the responsibility of county CPC committee secretaries, county heads and leaders at the upper levels must be investigated and affixed."

To seriously implement the urgent instruction of the CPC Central Committee and the State Council on curbing indiscriminate tree-felling, in light of the actual situation of the province, the conference put forward the following demands:

1. CPC committees and governments at all levels must further deepen their understanding, unify their thinking, seriously inspect the situation in implementing the urgent instruction some time ago and, in light of the existing problems, take vigorous measures to implement the urgent instruction and the spirit of the circular of the provincial CPC committee and the provincial government.

2. In the course of implementing the urgent instruction, all places must completely deal with the cases of sabotage of forests. In coordination with each other, public security organs, procuratorates, courts and industrial, commercial and forestry departments must immediately go into action and severely and quickly deal with the serious cases, particularly those who are still sabotaging forests.

3. It is necessary to do well in fixing rights of forests, fixing private forests and fixing the forestry production responsibility system. In places where the "three fixes in forestry" have or have not been completed, those who have not lumbered in a planned way or have lumbered beyond their quotas must immediately stop lumbering and make written reports to the provincial CPC committee and the provincial people's government. The timber lumbered above their quotas must be purchased by the provincial forstry department in a unified way and the profits from these sales must all be earmarked as provincial afforestation funds. All free timber markets must be closed down immediately. No units or individuals are allowed to buy or sell timber illegally; otherwise, they will be punished for violating the law of forests.

4. It is imperative to do well in preventing hill fires.

5. CPC committees and governments at all levels must grasp the implementation of the urgent instruction as a current major task and regard the protection of forests and the development of forestry as a long-term task in the future. All prefectures, autonomous prefectures, municipalities and counties must each assign a leading comrade to take charge of this work and to set up a work group with the participation of relevant departments.

The conference demanded that in the coming winter and spring all places do well in curbing indiscriminate tree-felling, in curbing reclamation of land from forests, in preventing hill fires and in the "three fixes in forestry."

CSO: 4007/67

TIE YING PRAISES RESPONSIBILITY SYSTEM

OW052059 Beijing XINHUA Domestic Service in Chinese 1308 GMT 3 Dec 82

[Text] Beijing, 3 Dec (XINHUA)--NPC Deputy Tie Ying spoke at a meeting of the second group of the NPC Zhejiang delegation discussing Premier Zhao Ziyang's report on the Sixth 5-Year Plan.

He said: A lot of work has to be done in order to create a new situation of our economic construction, fulfill the Sixth 5-Year Plan and achieve the strategic objective of quadrupling industrial and agricultural output value. Considering the situation of Zhejiang, we should particularly make more efforts to emancipate our minds and have the courage to reform.

He said: We have had profound experience in agricultural questions. The system of responsibility for production is a breakthrough to create a new situation of agricultural production. It is also a new way to develop agriculture devised by the hundreds of millions of peasants in the course of practice under the guidance of the guidelines of the 3d Plenary Session of the 11th CPC Central Committee. However, many of our comrades at the beginning did not have sufficient understanding of this great creation by the broad masses of peasants. Particularly there were heated disputes over whether it is advisable to implement the system of fixing farm output quotas on a household basis and the system of "bao gan dao hu" [under the unified management of the production team, each household retains everything produced on the land assigned to it after paying taxes and contributing its share to the accumulation and public welfare funds as a member of the collective] in fairly developed agricultural regions. We too had quite a few misgivings. Now the masses' practice has given an affirmative answer to this question--on the question of the system of responsibility for production, the economically more developed regions are "no exception" because the system of responsibility for production by fixing output quotas under a contract can remarkably increased production there as well.

He said: Recently several comrades of the provincial party committee and I visited Jiaxing Prefecture and conducted investigations and studies there. We visited some communes and production brigades and teams of various types. Some of them were in a backward situation for a long time. After they implemented the system of fixing output quotas on a household basis or the system of "bao gan dao hu," they increased the production of everything and improved their situation in a year. Since the implementation of the system of responsibility for production by fixing output quotas under a contract, some high-yield units have further increase their production. All the cadres and people praise the system of responsibility by fixing output quotas under a contract and describe it as "capable of tapping the potential of high-yield brigades and teams, demonstrating its might at low-yield brigades and teams and having great appeal to peasant families." It is like a "magnet" attracting the peasants to march towards becoming "well-to-do."

Tie Ying pointed out: The question concerning the system of responsibility for agricultural production has on the whole been emancipated enough. We still have to further emancipate our minds in order to further develop and perfect the system of responsibility for agricultural production and to reform the economy as a whole. Particularly in industrial and commercial fields, we need to emancipate our minds even more and make determination to reform in order to enliven the economy and create a new situation. At present, commodity circulation in rural areas is choked and sluggish. This conspicuous problem will impede rural economic development if it is not solved.

Ti Ying held: In order to emancipate our minds and have the courage to reform, we must go among the masses to conduct thorough investigations and studies. Since the 3d Plenary Session of the 11th CPC Central Committee, the masses have devised many creations and gained a great deal of experience through practice. This is greatly helpful to us in further emancipating our minds, widening our views and stimulating our thinking. At present, the leading organs at all levels in our province are formulating plans and studying how to achieve the strategic objective of quadrupling industrial and agricultural output value. The planners must go among the masses to conduct investigations and studies. It is meaningless if they just consult past data, reason according to the past growth rate of total industrial and agricultural output value, or merely ask the lower levels to abide by the demand for "quadrupling the output value" put forward by the 12th CPC National Congress. In this way, they will be unable to work out any inspiring and feasible plans.

Tie Ying said: When formulating agricultural development plans, some comrades rely only on past data to consider questions and fail to take into full account enthusiasm fired among the masses since the implementation of the responsibility system. Therefore, they always think that it is very difficult to make great developments in agriculture. They even lack the confidence that our agricultural production can be restored to the 1979 level. In fact, the agricultural growth in some localities in recent years is much bigger than in the past. During my recent investigation tour in Jiaxing Prefecture, I gathered some contrasting materials. I think that they are quite convincing. One is contrasting material on grain production between Tiaonan commune and Zhenxi commune in Huzhou Municipality, between Zhongjiabing production brigade and Xiaohengjie production brigade under Shanxi commune in Jiashan County, and between 59 production teams of Xiaocun commune in Tongxiang County and 85 other production teams in the same commune. While their production conditions are basically the same, the per-mu grain yield of those implementing the system of fixing output quotas under a contract is generally about 200 jin bigger than others working under contract for small sections of land. Another is contrasting material on silk cocoon production. The silk cocoon production of Huzhou Municipality this year increased by 12 percent compared with last year; however, the rates of increase in Huzhou's Tangnan, Tiaonan and Zhacun communes, that implement the system of fixing silk cocoon output quotas on the individual basis, are 50.4 percent, 36.3 percent and 30.4 percent respectively, larger than the municipality's average rate of increase. The third is contrasting material on inland pond fish breeding. On an average, the fish production of Xiaang commune in Huzhou Municipality increased by 16.5 percent this year, but seven of its production teams that have contracted fish ponds to commune members' families yielded a 60 to 70 percent increase. These facts show that even the more developed agricultural regions also have great potential to increase production. The thing is, we must eliminate "leftist" influence, adopt an ideological line of seeking truth from facts and raise our consciousness in implementing the line, principles and policies laid down since the 3d Plenary Session of the 11th CPC Central Committee. This is an indispensable subjective condition for fulfilling the Sixth 5-Year Plan and achieving the strategic objective of quadrupling industrial and agricultural output value.

CENTRAL GROUP TO INVESTIGATE GUANXI FOREST CASE

HK170801 Hong Kong WEN WEI PO in Chinese 17 Nov 82 p 3

[Special dispatch by Tai Bo [1132 0130]: "Central Discipline Inspection Commission Work Group Arrives Nanning To Investigate Looting of Forest Farm"]

[Text] Nanning--A work group of the Central Discipline Inspection Commission led by Cheng Xin, a cadre at the ministry level, arrived in Nanning early in November. The group will help the Guangxi Regional People's Government's serious investigations and deal with a case which occurred in the Gaofeng Forest Farm. Over the past year or so, many state-owned forest trees in this farm have been looted and a large area of forest has been destroyed.

The Gaofeng Forest Farm, which covers an area of 640,000 mu, is one of Guangxi's major artificial forest bases. It has 460,000 mu of artificial pine and fir forest. Since the second half of 1979, the trees in this farm have been continuously looted by nearby communes and brigades. In a branch farm at the Taiping commune, Wuming County, alone, nearly 6,000 mu of forest has been looted and damaged, and the forest guards have often been scolded, beaten and threatened by the looters.

What is more serious is that the looting of the Gaofeng State Forest Farm was led and organized by some county, commune and brigade cadres in Wuming County. In April and June this year, some party members and cadres in the office in charge of the work concerning commune and brigade enterprises in Taiping Commune, Wuming County, together with some party members and cadres of Wenxi and Tonggui brigades, employed more than 90 laborers from other areas and brazenly felled large numbers of full-grown trees in the Aisha branch farm with the diesel-powered circular saw they had installed. They then processed the timber for on-the-spot sale.

How could these people dare to ignore state law? It is because some leaders of the Wuming County CPC committee and people's government supported, encouraged and provoked them. At a meeting to discuss the disputes between the forest farm and nearby communes and brigades, one of this county's chief cadres went so far as to call for continuous looting of state-owned forests. He beat his breast and said: "Do not be afraid! I will be responsible for all that might happen. If anyone is to be imprisoned, I will be the one!" It was discovered through investigation that this responsible cadres [words indistinct] "rebellion" during the Cultural Revolution. In 1974, he wrote some vicious articles to criticize the capitalist roaders and, for this, he was sent to study in the Hongqi editorial office, which was then controlled by Yao Wenyuan. In 1975, he returned to Guangxi and was promptly appointed by some people deputy chief editor (second in command) of GUANGXI RIBAO. He was a most active henchman in the movement to "criticize Deng Xiaoping" and to counter the rightist deviationist trend to reverse correct verdicts. After the fall of the "gang of four," since there were too many reproaches concerning his promotion, some people had to transfer him to the county level and let him take up his present post in Wuming County, so that he would be able to be "promoted step by step" again "in the future." The masses have a deep hatred for these people who rose to prominence through rebellion and who have neither learning nor skill. They strongly demand an investigation and the assigning of responsibility for the criminal case which occurred in the Gaofeng Forest Farm.

CSO: 4007/67 END
